INDEX OF CHEMISTRY AND INDUSTRY REVIEW
Vol. I. 1923

A

PAGE

Abrasive materials in the United States in 1921 717
  New "Sira" ——. 1123
Abrasives, Artificial ——. M. Barrett 710
Absorbents, Solid; Use of ——. R. Furness .. 850, 1164
Absorption tower; Study of the ——. M. B. Donald.. 1139
Académie des Sciences 422, 541, 622, 680, 734, 772, 791, 832, 910, 986, 1010, 1082, 1187, 1235
Accelerators; Analysis of organic rubber vulcanising ——. T. Callan and N. Strafford 1209
  Analysis of rubber vulcanising ——. 1160
  Methods for comparing the activity of ——. .. 1160, 1208
Acetic acid consumption in Malaya 998
Acids; Chemistry of the glutaconic ——. 1033
  Polarity effects in the isomeric ω-bromo toluic ——. .. 1134
Acidity; Co-ordination and ——. T. M. Lowry 1048
Agar-agar industry of Japan 1191
Agriculture in Jamaica 156
Air; A new process for dehydrating ——. P. Dumanois .. 910
  Liquid; Explosions in —— rectification plant 152
  Rapid admixture of hot combustible gases with ——. .. 1080
Alchemist; Thomas Norton, an —— of Bristol. E. J. Holmyard 574
Alcohol; New denaturant for ——. Bordas and Touplain 541
  Denatured; Notes on —— in Canada. R. E. Gilmore 369, 802
  Excise duty on ——. 278
  industry in Formosa 753
  Methyl; Concentration cells in ——. 680
  industry 19, 682
Alembic Club 732
Algeria: Cream of tartar industry in France and ——. .. 214
  Mineral output in —— in 1922 699
Alizarin, German.. .. .. 245, 1068
Alkali centenary 383, 487
Alkali; Production of —— by bacteria as registered by different indicators ——. J. A. Reddie 421
Alkali works; Report on ——. 990
Alloy; New —— for firebars 375
Alloys; Cathodic behaviour of ——. S. Glasstone 1162
  Effects of rate of cooling on the density and composition of metals and ——. 907
  Magnesium; Mechanical properties of ——. L. Aitchison 302
  resistant to corrosion; Discussion on ——. 398
  Structure of ——. W. Rosenhain 472
  ultra-light; Magnesium and other ——. A. Portevin .. 542
Aluminium, 1919–21 306
  and bauxite in the United States in 1921 966
  hollow-ware 246
  hollow-ware; Imports of ——. 308
  industry in Germany 402
  The constitution and age-hardening of the quaternary alloys of ——. L. V. Gayler 908
American Association for the Advancement of Science .. 98
American Chemical Prize 1113
p-Amidophenol; Determination of —— in presence of metol. W. F. A. Ermen 538
Ammonia; Alkalinity of ——. A. E. Clarence Smith .. 578
  and sodium hypobromite; Reaction between ——. .. 368
  Basic strength of —— and allied bases. R. M. Caven .. 164
  Strength of —— as a base 127
  Synthetic —— in Spain 524
Ammonium hydroxide; Existence of —— in solution. T. S. Moore 343, 641
  R. M. Caven 448, 744

PAGE

Ammonium; Existence of —— in solution 564
  phosphates 353
  sulphate (export regulations) 775
  sulphate; Price of ——. 1923 185
Anæsthetics; Measurement of the degree of anæsthesia produced by local ——. T. Regnier 986
Analysis; Electrometrical methods of ——. 1079
  of organic rubber vulcanising accelerators 1209
  of rubber vulcanising accelerators. T. Callan and N. Strafford 1160
  Short cuts in ——. J. R. Green 1070
Angola; Report on ——. 1923 1170
Annali di Chimica Applicata 399
Anthracene; Crystalline structure of ——. 271
Anthrax 91
Antimony in the United States in 1921 327
Aphrogen, a new saponin in Germany 214
Argentina; Report on —— 1921–22 406
Argentojarosite; New silver mineral in the United States .. 660
Arsenic; Discussion on detection of small quantities of ——. 124
  industry in Canada 682
  industry in the United States 276
  in malt 151
Asbestos 1199
  in the United States in 1921 915
Ashes, Boiler; Combustible matter in ——. W. S. Patterson 904
Association of British Chemical Manufacturers 51, 150, 273, 399, 497, 622, 716, 910, 1010, 1107, 1237
Association of Tar Distillers 172
Atom; The Bohr ——. J. D. Main Smith 1073
  Bohr —— and covalency. N. V. Sidgwick 1203
  Bohr —— and the periodic law. N. V. Sidgwick .. 901
  Modern theories of the structure of the ——. H. S. Allen 13, 338
Atomic constitution; Theory of spectra and ——. W. L. Bragg 690
  theory and the progress of chemistry. E. Pascal .. 912
Atoms, Solute: Volumes occupied by —— in certain metallic solid solutions and their consequent hardening effects. A. L. Norbury 1163
Australia; Gold discovery in Western ——. 326
  Gold output in —— 1922 242
  Metal output in —— in 1922 659
  Metallurgy; New chair of —— in ——. 1041
  Mineral output in Queensland in 1922 699
  Oil; Eucalyptus —— as a motor fuel 818
  Report on —— 1920–1922 107
  Silver-lead ore discovery in Queensland 1166
  Sugar industry in ——. 430, 698
  Sulphur output in ——. 1150
  Superphosphate manufacture in Tasmania 734
  Zinc concentrates in ——. 735
Austria; Coal and iron industry in 1922 433
Austria Hungary; Partition of industries of ——. 154
  Soapstone; New deposit of ——. 934

Authors of Signed Articles:—

  Abrams, A. 1094
  Allen, H. S. 338
  Armstrong, Dr. E. F. 603, 950
  Armstrong, Prof. H. E. 923
  Bailey, H. J. 362
  Baly, Prof. E. C. C. 256
  Barrett, M. 710
  Bragg, Prof. W. L. 690
  Brindley, W. H. 64
  Butler, R. R. 980
  Callan, Dr. T. 466, 828

PAGE

Authors of Signed Articles—*continued.*
  Caven, Prof. R. M. .. 164, 448, 744
  Cheetham, Howard .. 679
  Collins, H. F .. 88, 114
  Coster, Dr. D., and Dr. G. Hevesy .. 258
  Craven, Dr. E. C. .. 577
  Crooks, W. E. .. 955
  Dauvillier, A. .. 1182
  Deschiens, Maurice .. 228
  Donnan, Prof. F. G. .. 892
  Drummond, A. A. .. 769
  Drummond, Prof. J. C. .. 811
  Duff, Prof. .. 1094
  Easterfield, T. H. .. 936
  Ehrhardt, Dr. E. F. .. 314
  Ermen, W. F. A. .. 486, 538
  Furness, Rex .. 196, 358, 728, 850, 1001, 1126
  Gilmore, R. E. .. 802
  Gray, H. H. .. 225, 956
  Greenfield, G. J. .. 390, 417
  Hevesy, Dr. G. von .. 258, 929
  Higgins, S. H. .. 1026
  Hind, H. Lloyd .. 554
  Hinchley, Prof. J. W. .. 489, 883, 911
  Hirst, S. .. 140
  Holmyard, E. J. .. 387, 574, 958, 976
  Hopkins, Prof. F. Gowland .. 676
  Howe. H. E. .. 610, 530
  Huebner, J. .. 227
  Ingold, Dr. C. K. .. 612
  Jones, G. C. .. 211
  Jones, T W. .. 1099
  Jordan, Dr. L. A. .. 362
  Lander, Dr. C. H. .. 1052
  Levinstein, Dr. H. .. 259, 294
  Louis, Prof. H. .. 252, 286
  Lowry, Prof. T. M. 43, 224, 316, 412, 462, 711, 747, 1004, 1048
  McBain, Prof. J. W. .. 615
  McClelland, N. .. 936
  McKee, Prof. R. H. .. 193
  Merriman, R. W. .. 290
  Moore, Prof. T. S. .. 343, 641
  Morgan, Prof. G. T. .. 868
  Morgan, Prof. J. J. .. 1178
  Partington, Prof. J. R. .. 636, 790
  Patterson, Prof. T. S. .. 692
  Patterson, W. S. .. 904
  Pope, Sir W. .. 5, 52, 72, 117, 169, 809
  Price, Dr. T. Slater .. 292
  Prideaux, Dr. E. B. R. .. 672, 954
  Race, Joseph .. 166
  Radcliffe, L. G. .. 64
  Rideal, Dr. E. K. .. 614
  Rutherford, Prof. Sir E. .. 874
  Semmens, E. S. .. 954
  Shatwell, H. G. .. 1028
  Shimomura, Akira .. 617
  Shimomura, Kotaro .. 556
  Sidgwick, Dr. N. V. .. 901, 1202
  Silberrad, C. A. .. 924
  Smith, Dr. A. E. Clarence .. 578
  Smith, Dr. J. D. Main .. 847, 1072
  Spiers, C. H. .. 534
  Sutton, F. C. .. 710
  Thompson, Edwin .. 1152
  Thorpe, Prof. J. F. .. 612
  Tilden, Sir W. A. .. 138
  Urbain, G. .. 764
  Usherwood, E. H. .. 1246
  Vakil, K. H. .. 788
  West, J. H. .. 1024
  White, Rev. B. V. .. 120, 202, 319, 583
  Whitehead, H. R. .. 1226

B

Bacteria; Action of —— on cellulosic material .. 491
Bacteriology; Ellis's practical —— for chemical students.
    D. Ellis .. 1037, 1143
    R. F. Hunwicke .. 1038
    A. Renshaw .. 1060
Barium minerals in Canada .. 80
  Presence of —— and strontium in natural brines. A. G. Francis .. 494
  products; Barytes and —— in the United States in 1921 752
Barytes and barium products in 1921 in the United States .. 752
  industry in Shropshire .. 215
Base metal industry; Review of the ——. Sir R. Redmayne 424
Bauxite and aluminium in the United States in 1921 .. 966
Bauxites, clays, etc; Behaviour of —— on heating. H. S. Houldsworth and J. W. Cobb .. 516
Bayberry oil .. 241, 275, 325, 373, 400
Bees; effect of insecticides on ——. .. 750
  Lead arsenate sprays and ——. .. 624, 658
Belgian Congo; Investigation of Uranium minerals in the ——. .. 1061
Belgium; Metallurgy in ——. .. 1061
  Report on —— in 1922 .. 545
Bentonite in Canada .. 80
  Occurrence and uses of ——. .. 433
Benzene derivatives; An empirical rule for substitution in ——. .. 348
  series; An empirical rule for substitution in the ——. .. 453
Benzol recovery; Practice and control of —— from gas and the use of solid absorbents. R. Furness .. 850, 1164
Biochemical Society .. 208, 372
Birmingham: New laboratory at the —— technical school 1113
  University Chemical Society .. 101, 1036, 1105, 1236
Bismuth industry in Transbaikalia .. 432
Bleaching .. 1123
  industry; Chemistry and the ——. S. H. Higgins .. 1026
Bonds, Double; Polarity of ——. .. 302
Books Reviewed.—*See under Reviews.*
Boric acid; Estimation of —— in "liquid eggs" and other foodstuffs. G. Monier-Williams .. 372
  acid; Power and —— from natural steam in Tuscany .. 1022
Boron; Atomic weights of —— and silicon .. 243
Brazil; Report on —— 1915–1922 .. 82
Brewing industry; Some points in the history of fermentation particularly as applied to the ——. .. 1234
British Association .. 80
British Association of Chemists .. 1084
British Chemical and Dyestuffs Traders' Association .. 508
British Chemical Plant Manufacturers' Association .. 791
British Chemical Standards' Movement .. 324
British dyestuffs industry .. 1189, 1214
British Empire Exhibition, 1924 .. 40, 303, 1011, 1264
British Engineering Standards Association .. 816
British India; Cinchona and quinine in ——. .. 269
  Coal industry in ——. .. 183
  Copper deposits in ——. .. 1200
  Distillation works in Mysore .. 659
  Glue-making in Madras .. 153
  Groundnut crop; Forecast of the ——. 1922–23 .. 350
  Groundnut crop; Forecast of the ——. 1923–24 .. 1216
  Indigo crop; Forecast of the ——. 1922–23, 1923–24 105, 1167
  Iron works in Mysore .. 659
  Oilseeds; Forecasts of winter —— crop .. 131, 374, 659
  Opium output in ——. .. 456
  Salt duty .. 405
  Sesamum crop; Forecast of the ——. 105, 214, 566, 940, 1238
  Sugar-cane crop; Forecast of the ——. .. 326, 938, 1238
Brass; Cause of red stains on sheet ——. .. 907
British Industries Fair .. 405, 782
British Leather Manufacturers' Research Association .. 1213
British Malaya; Acetic acid consumption in ——. .. 998
  Chemical trade in ——. .. 250
  Dyes, Coal-tar; Imports of —— into ——. .. 782
  Rubber exports in —— in 1922 .. 162
British Non-Ferrous Metals Research Association .. 169
British West Indies; Report on ——. .. 439
Bromides; Crystalline —— of linseed oil .. 1210
Bromine; Action of —— on phenylhydrazones. .. 423
  in the United States in 1921–22 .. 955
Building materials in the U.S.A. in 1921 .. 1112
  materials; Science of ——. B. Haberstroh .. 566
  stone; Preservation of ——. .. 1167
Bulgaria: Report on —— in 1921–23 .. 662
  Salt production ——. .. 626
  Sugar-beet crop of ——. .. 594
Burettes; Notes on ——. V. Stott .. 583

C

Cadmium in the United States in 1921 and 1922 .. 773
Calcium carbide industry in Norway .. 455
  carbide inquiry; Sir A. Colefax .. 75, 239
    Sir W. Pope .. 5, 117, 169
  chloride in the United States in 1921–22 .. 955
  cyanamide industry in Norway .. 455
  cyanamide; Toxic action of ——. .. 16
  lactate .. 454, 522
Calorimeter; Electrical contacts for bomb ——. .. 913
Calorizing process .. 552
Camphor and celluloid industries of Japan .. 682, 922
  Proposed cultivation of —— in the Philippines .. 430
  Refined natural *d*-; The melting point and iodine value of ——. M. S. Salamon .. 495
Canada. Alcohol, Denatured ——. .. 369, 802
  Arsenic industry .. 682
  Barium minerals .. 80
  Bentonite .. 80
  Carbonisation; Low-temperature ——. .. 753
  Chemical industry in 1921 .. 940
  Coal-distillation plant; New low-temperature ——. 1166
  Cobalt output in 1922 .. 1216
  Felspar; New —— deposit .. 734
  Hydro-electric progress in 1922 .. 350
  Iron and steel industry in 1920–1921 .. 131, 401, 625
  Leather industry in 1921 .. 643
  Mineral output in 1921 .. 914

PAGE

Canada—*continued.*
  Mineral output in 1922 .. 374, 989
  Mineral output in 1922–23 .. 941
  Minerals; Output of non-metallic —— in 1922 .. 1176
  Mining industry in Quebec .. 773
  Paper and pulp industry in 1922 .. 1012, 1238
  Nickel in ——. .. 1041
  Petroleum; Crude —— in 1922 .. 1216
  Report on ——. .. 57, 1259
  Silica in —— .. 1013
  Silk; Prospects for an artificial —— industry .. 659
  Strontium minerals in ——. .. 80
  Titanium in ——. .. 543
  Trade in —— in 1922–23 .. 762
Canal construction; A proposal regarding ——. W. R. Hodgkinson .. 1060
Cantharidin; A new source of —— in the United States .. 833
Carbon; Absorption activity of ——. J. B. Firth .. 451
  Activated —— *v.* silica gel .. 1141
  black. S. A. Wisdom .. 1134
  black; Trade in ——. .. 378
  dioxide; Absorption of ——. .. 857
  monoxide; Formula of ——. .. 681
  monoxide in gas .. 595
Carbonisation; Low-temperature ——. .. 858, 1100
  Low temperature —— in Canada .. 753
Carbons, Arc-lamp .. 353
Casein; Estimation of fat in ——. .. 146
  output in 1922 .. 833
Cassiterides, The .. 696
Catalysis .. 103, 1214
  Contact. E. K. Rideal .. 614
Cells; Concentration —— in methyl alcohol J. Grant and J. R. Partington .. 680
Celluloid and camphor industries of Japan .. 682
Cellulose, Acetate; Elasticity of organogels of ——. E. W. J. Mardles .. 519
Cellulose fermentation with special reference to the utilisation of spent hops and brewers' grains .. 237
Celluloses; Behaviour of the principal —— towards iodine and dyestuffs. J. Huebner and J. H. Sinha .. 470
Celtium .. 765, 784, 792, 832, 884
  The high-frequency lines of ——. A. Dauvillier .. 1182
Cement industry; Developments in the ——. R. Furness 728
  industry in Esthonia .. 1264
  market in Jamaica .. 20
  output in the Far East .. 626
  Portland —— industry of South Africa .. 818
  Portland; Research on ——. .. 402
Ceramic Society .. 516, 1008
Ceylon in 1921 .. 190
Charcoal; Determination of the density of ——. .. 680
  Catalytic decomposition of hydrogen peroxide solution by blood ——. .. 1162
Chemical action, particularly at solid surfaces .. 96
  change; Linear *v.* logarithmic rate of ——. .. 1163
  congress; Proposed international —— in South America 699
Chemical Engineering Group. *See under* Sections.
Chemical export trade to Germany .. 634
  factories in the Ruhr district .. 308
  firms, German; Capital increases of ——. .. 336
Chemical Industry Club .. 1140, 1160
Chemical industry of Canada in 1921 .. 940
  industry and the Ruhr occupation in Germany .. 431
  industry in France. *See under* France.
  industry in the Netherlands .. 156
  industry in Poland .. 774
  industry in Russia, 1922 .. 443
  industry; Profits in the Italian ——. .. 698
  industry; Legislative and departmental interference with ——. Prof. H. E. Armstrong .. 9, 23, 47, 91
  industry; Progress of the British —— since 1914. H. Levinstein .. 259, 294
  industry; Wages in the German —— 1922 .. 327, 753
  Organic —— industry in the United States .. 374
  prize in America .. 1113
Chemical Society .. 13, 72, 81, 129, 180, 238, 301, 423, 431, 496, 588, 656, 984, 1033, 1080, 1105, 1136, 1211
  Some early years at the ——. Sir W. A. Tilden .. 138
Chemical society; German —— and trade with Japan .. 20
  society; A new —— in the United States .. 131
  standard; New British ——. Basic slag "A" .. 183
  trade in British Malaya .. 250
  trade of Finland in 1922 .. 762
  trade of Germany in 1922 .. 443
  trade regulations .. 185
  trade, Heavy; Wages in —— .. 382
  trade in the United States in 1922 .. 444
  works; New heating system for ——. .. 544
Chemicals at the British Empire Exhibition, 1924 .. 40
  Fine. E. I. Lewis .. 497
  Imports of —— into the United States .. 572
  Japanese heavy —— market in 1922 .. 1091
  Prices of —— in Germany in 1922 .. 443
  Prices of —— in Germany in 1923 .. 834
  Synthetic organic ——. .. 290

PAGE

Chemist; Al-Rāzi as a ——. .. 373
  Government; Report on work of the —— for year ending March 31, 1923 .. 969
  and business training .. 1039, 1109
  and the public .. 1085, 1143
Chemist and industry. H. H. Gray .. 956, 1039
  and industry. J. H. West. .. 1024
  Functions of the —— in the departments of the Canadian Government .. 231
  Industrial ——. .. 1058
  Title of ——. 274, 304, 326, 373, 426, 427, 453, 475, 600
  Work of the —— in connexion with the textile industries. L. L. Lloyd .. 1159
  Analytical. E. M. Hawkins .. 1059
Chemistry and Industry. E. F. Armstrong .. 603
  Correspondence relating to ——.
    Pope, Sir W. .. 2
    Brunner, R. .. 3
    Lane Fox, Col. G. R. .. 3
    Walker, Sir J. .. 4
    Kestner, Monsieur P. .. 4
    Muspratt, Sir M. .. 4
    Reavell, J. A. .. 22
    Leverhulme, Rt. Hon. Viscount .. 22
    Alexander, Brigadier-General Sir W. .. 23
Chemistry and the bleaching industry. S. H. Higgins .. 1026
  and the safety of the workers .. 229
  Palace of ——. .. 26
  Applied; Reports of the Progress of ——. .. 446, 585
  Arabic; Critical examination of Berthelot's work upon ——. E. J. Holmyard .. 959, 976
  as the maker and breaker of nations .. 205
  International Union of Pure and Applied —— at Cambridge .. 645
  British —— and German publications .. 593
  Colloid; Bibliography of —— in the United States .. 566
  Colloid .. 274
  Colloid; Recent advances in ——. A. V. Slater. .. 1187
  Colloid; Study of soap solutions and its bearing upon —— 615
  Industrial; Third congress of —— in France .. 857
  in France in the XVIIth and XVIIIth centuries. C. A. Silberrad .. 924
  in the electrical industry. A. A. Drummond .. 769
  in mediæval Islam. E. J. Holmyard .. 387
  in relation to tinplate manufacture. H. J. Bailey .. 362
  of hafnium. G. von Hevesy .. 929
  of polycyclic structures in relation to their homocyclic unsaturated isomerides. R. C. Grimwood, C. K. Ingold and J. F. Thorpe .. 1035
  of the glutaconic acids. F. R. Goss, C. K. Ingold and J. F. Thorpe .. 1033
  of the three-carbon system. Part I. S. F. Birch, G. A. R. Kon, and W. S. G. P. Norris .. 423
  Old and new problems in agricultural —— .. 1079
  Physical; Symposium on the —— of the photographic process .. 562
  Recent developments of electrometric methods in analytical —— .. 1079
  Recent progress in ——. H. Levinstein. .. 984
  Advances in our knowledge of the —— of starch .. 1036
  Importance of —— to the community .. 1032
  Atomic theory and the progress of —— .. 912
  —the key to international relations. H. E. Howe 510, 530
  The new —— .. 1102
Chemists' Club; Silver anniversary of —— in New York 1041
Chile; Copper output of —— .. 1150
  Nitrate industry of —— .. 819
  Report on —— 1922–23 .. 1169
  State aid for the iron and steel industry of —— .. 1091
  Sulphur industry in —— .. 558
China: gallnuts; Output of —— .. 467
  Report on —— in 1921, 1922 and 1923 .. 108, 1219
  Saltpetre in —— .. 155
Chlorselenic acid; Selenium trioxide and —— .. 1034
Chromite in the United States in 1921 .. 793

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, JANUARY 5, 1923 No. 1

EDITORIAL

THE Council in deciding to issue the Journal of the Society of Chemical Industry weekly has taken a bold, perhaps a rash course. The Journal has from its commencement made progress, and has steadily improved its usefulness and circulation. It has by no means reached a final state ; as time proceeds, and as the editorial staff becomes more accustomed to the new venture, further experiments will be made and new features will appear in the Journal. Some of these will be successful, some no doubt will be found to be unsuitable and will be discarded. Mistakes will naturally be made, and our readers will complain of omissions and errors of judgment ; "that no grievance ever should arise in the commonwealth, that let no man in this world expect ; but when complaints are freely heard, deeply considered, and speedily reformed, then is the utmost bound of civil liberty attained, that wise men look for." We shall endeavour to profit by this excellent and time-honoured precept, and with the support of our readers, of which the letters we print in this issue are abundant evidence, we look forward to the new conditions without any misgiving, believing that, when we have recovered from such a dislocation as the present change involves, we shall have opportunities of increasing the amount of matter in the weekly Journal, its attractiveness and its interest.

It is the ambition of the Council to have a Journal which will appeal to every one who is concerned with chemistry. Those who are engaged in teaching or studying the science, those who manufacture chemicals and chemical plant, whether they are directors, managers, chemists or salesmen, those who buy and sell chemicals, and those who direct the fortunes of this country from Whitehall and Downing Street, will all find something of value to them in our pages.

Our readers abroad—and these are a large and growing number—will be informed of the news and gossip in chemical circles not only in this country but in all countries in Europe, in America, and the other continents. Our Journal already circulates in every country where chemistry is practised, and it is one of our aims to enable our readers in every country to keep acquainted with the news in the rest of the world. We rely on their co-operation and help.

* * *

The beginning of a New Year provides us with recollections and anticipations which we usually do not indulge in at other seasons. We have a sort of holiday, we assemble family parties, we gossip over by-gone days, and step aside for a moment to survey from a suitable mound the course of our lives. So far as this Journal is concerned the prospect is one of sudden change ; a well-disciplined and orderly march has enabled information on one special branch of knowledge to be purveyed at the leisurely intervals of twice a month. Now we must, within three days' of the issue of our last volume, commence the publication of a new one, at double the former speed and dealing with a larger domain of learning. We are in a measure merchants of knowledge ; we have to acquire our news, our articles, our cargoes of weighty matter; these must be sampled, re-packed, put into an attractive form, and distributed in quantities such as our customers require and at very definite times. We can never plead delay in transit, barratry, Acts of God, or the King's Enemies or any of the other moving accidents which are mentioned in detail in charter-parties, bills of lading and sundry commercial documents. Readers receive their weekly Journals with a regularity which should be a marvel, but it is taken as a matter of course. "We never came into our dining-room but at twelve and six o'clock we found excellent meat and drink on the table; our clothes were never worn out, but next morning a tailor brought us a new suit: and without question it will be so ever." So we think, carelessly, but at the New Year, when they survey the world around, we ask our readers to spare a few moments to reflect on the responsibilities of printers and editors.

* * *

America is a great country and has ideas commensurate with its greatness. We mention elsewhere an important announcement which will excite feelings of admiration and envy in the minds of British Chemists. The Allied Chemical and Dye Corporation, of which Dr. W. H. Nichols is Chairman, announced an annual gift of twenty-five thousand dollars to reward the American chemist who contributes most to the benefit of the science and the world. This is an extremely handsome proposal, well worthy of the Corporation which makes it, the Chairman who announces it and the country of its origin. It recalls the valuable Nobel Prizes, the great donations of the late Monsieur Solvay and some other benefactions. In this country we lag behind in the endowment of science. We are a small country—so is Sweden—so is Belgium. At the moment we are a poor country, and our once wealthy companies and our once wealthy men are not in a position to make princely gifts. But this was not so eight years ago, and will not be so eight years hence. The spirit of generosity remains with us yet, and we have comparatively recent instances in some handsome endowments handed over to the Universities of Oxford and Cambridge and the bequests made by Dr. Ludwig Mond and Dr. Messel. Even at the present time something might be done in this country for the advancement of chemistry by those who are comparatively well off. No amount of money will enable a second class chemist to become one of the first rank, but money will be a great help in organising the science, in promoting the application of it to industry, in the speedy publication of chemical information, in the easier means of enabling chemists here to become acquainted with their colleagues all over the world and the new discoveries which are being made.

LETTERS

From

Sir William Pope, K.B.E., F.R.S.

President of the Federal Council for Pure and Applied Chemistry

The decision of the Council to issue the JOURNAL weekly from the beginning of 1923 marks a fresh development in the activities of the Society of Chemical Industry. The Society was founded early in 1881 with a membership of 297, and published a now rare volume of 60 pages of the proceedings at its first annual meeting. From the commencement of 1882 the JOURNAL of the Society was issued in monthly numbers under the editorship of our late friend, Mr. Watson Smith, and included from its first issue "Transactions" and "Abstracts" under continuous pagination. The JOURNAL became a fortnightly issue in 1902, and was continued in the same form until the end of 1917; since January, 1918, it has appeared in fortnightly numbers, each containing an instalment of the "Review," the "Transactions," and the "Abstracts," with a separate pagination for each section.

The history of the Society's publications is one of steady progress; the aim of the Council has always been to increase the amount of information placed before the members and to render that information available with ever-increasing promptness. This being the object in view, it is clear that the next step in advance consists in converting the fortnightly issue into a weekly one.

A fortnightly issue suffers under many disadvantages. The subscriber to a weekly journal learns to expect his copy on one particular day of the week, whilst a periodical which arrives fortnightly is apt to appear as an intruder which finds no allotted place in the week's routine. Further, current information of interest which can be served up fresh in a weekly journal, grows cold when it has to wait for a fortnightly issue. Considerations such as these provide a basis for many of the criticisms which have been directed against the "Review" from time to time; they indicate that the Society will grow in vigour and in usefulness with a weekly issue of its JOURNAL.

Naturally, a weekly journal must aim at the prompt dissemination of much information of general interest to chemists, and its success will depend largely upon the extent to which the enthusiastic collaboration of all chemists can be secured; reports of meetings of societies at which chemical topics are dealt with must be obtained and published at the earliest possible moment. After conference with the Federal Council for Pure and Applied Chemistry it has been decided to make the JOURNAL the official organ of that body for the purpose of enlisting the sympathy and aid of all the societies concerned with chemical affairs in what should be, to a greater extent than has been possible with the "Review," the chemical newspaper.

Whilst the JOURNAL will remain in every sense of the term the Journal of the Society of Chemistry, the new development represents an earnest attempt by the Society to amalgamate the corporate interests of chemical science and technology. Since the widened scope of the JOURNAL should secure for its more topical part, that represented by the present "Review," a circulation outside present members of the Society, it is proposed to change the title of this section to "Chemistry and Industry" and to place this on sale separately. For members of the Society, "Chemistry and Industry" will be issued in the same blue cover as the "Transactions" and the "Abstracts," each of the three sections being separately paged as at present. A tentative arrangement has been already made for supplying Fellows of the Chemical Society with "Chemistry and Industry."

The discussions concerning the new development have been lengthy, having extended over the last two years; they have been anxious ones, by reason of the magnitude of the financial responsibilities which the Society is assuming. The scheme of work which is now being embarked upon is the result of mature reflection and consideration; it may not be perfect in every detail, but the Council may be trusted to apply the appropriate remedy to any defects which experience may reveal.

The duty now devolves upon all interested in the chemical industry and chemical science of the Empire to promote the success of "Chemistry and Industry" by contributing items of news and articles of chemical interest and by using its columns for the ventilation and discussion of technical and scientific questions.

From

Colonel G. R. Lane Fox, M.P.

H.M. Secretary for Mines

It is with much pleasure that I hear of the intention of the Society of Chemical Industry to start a weekly Journal. The reputation of the present Journal is firmly established, and for many years now it has played an important part in bringing the results of Research work in Chemistry before those concerned in the industrial application of those results and before the public generally. It is of special interest to me now, as Secretary for Mines, that the Society and its Journal have made valuable contributions to the solution of the economic and safety problems of the great mining industry of this country, and I wish the Journal in its new form every success in all its spheres of work, but particularly in this.

From

Roscoe Brunner, Esq.

Chairman of Messrs. Brunner, Mond & Co., Ltd.

I am very interested in the decision of the Society of Chemical Industry to publish the Review portion of its JOURNAL weekly instead of twice a month, and I hope and believe that this new venture will be as successful as the efforts of its promoters deserve.

In the present state of world-trade everyone, whatever his political views or prejudices may be, must welcome every possibility of improving trade, and thus increasing the production of wealth upon which the standard of life of all depends.

After the Napoleonic wars at the beginning of the last century, the loss of wealth which had been incurred in those wars was rapidly restored by the vast and unprecedented growth of trade all over the world which, as is well known, was in the main due to the large number of scientific discoveries and the industrial application of them to increased production. A similar increase in the production of wealth is once again required to repair the tremendous losses of the late war, and to no industry can the world look with such hope and such confidence as to the Chemical Industry. In that industry there are always possibilities of discoveries, or the application of discoveries already made, which may revolutionise industrial methods and render available hitherto unsuspected sources of energy and wealth.

It seems to me that such a weekly journal as you propose to publish will be of great assistance in helping the Chemical Industry to realise these possibilities. You are wisely proposing, I notice, to deal with pure chemistry and physical chemistry, as well as with applied or industrial chemistry. This combination of the two aspects of the science should be of assistance both to the chemist primarily concerned with industry, and also to the pure scientist producing results some of which may prove of value to the manufacturer.

There is no doubt that in the past there has been some justification for the reproach levelled against British industry that it was not sufficiently alive to the possibilities of research work, and of the application of the results of research work to industrial processes. A considerable improvement has taken place in this respect both during and since the war, but there is still room for further improvement and for further co-operation between the industrialist and the scientist. In this matter your new venture should perform a very great service, and be of equal assistance to both parties. I am looking forward to its first number with considerable interest, and I feel certain that all those who have the Chemical Industry at heart will, as I do, give you their warmest wishes for its unqualified prosperity and success

From

Sir Max Muspratt, Bart.

Chairman of the United Alkali Co., Ltd.

You have asked me to write a few words concerning the suggested change in the issue of the "Review" portion of our Journal. I do so with pleasure.

In the first place, may I be allowed to congratulate those responsible for the proposal which appears to me to be one likely to appeal to the majority of the members and so add materially to the usefulness of our Society?

The Society of Chemical Industry, as the older members know, grew rapidly from a comparatively small and local beginning. Its Journal, with the publication of original papers, abstracts of patents, and chemical literature, received early recognition, and almost from the start became indispensable to any chemist interested in the industrial aspect of our science.

During the earlier period of the Society's existence, and whilst its membership and activities were confined to these Islands, monthly publication sufficed. The extension of membership and the foundation of Sections in the United States of America and the Colonies, coupled with the formation of other scientific associations dealing with special branches of chemistry and the consequent increase in the volume of research work published, naturally added to the pages of our Journal, and the present bi-monthly publication has fully justified its inception.

The initiation of the "Review" portion of the Journal was again clearly in the line of progress. For its past success I feel the congratulations of all members will be accorded to the late editor, Dr. E. H. Tripp. There is no doubt the present "Review" is a distinct success; it possesses in its "News and Notes" a human element and permits the introduction of many items of interest which might less readily find a place in the purely scientific pages.

The early publication of abstracts of papers read before our own Sections, or reports of meetings of other societies; the summarised accounts of progress in special branches of science and technology are of interest to all, but perhaps more particularly to those busied with the commercial aspect of industry who desire reports of progress to be early and concise.

I heartily welcome the suggestion of weekly publication of this interesting and valuable portion of our Journal, and I wish the Society and yourself as the new editor all success in the venture.

From

M. Paul Kestner

President of the Société de Chimie Industrielle

Vous voulez bien m'apprendre que la Society of Chemical Industry a décidé de faire paraître dorénavant hebdomadairement son bulletin, ou tout au moins la portion de ce bulletin consacrée à la revue.

En me faisant cette communication vous voulez m'associer l'un des premiers à votre joie et à votre légitime fierté. Vous me savez un des plus anciens membres de votre Société, l'un de ses plus fidèles amis; vous avez eu la délicate pensée que je devais être l'un des premiers à connaître l'heureuse nouvelle; je vous en remercie.

A cette occasion, je me souviens du plaisir que déjà j'avais ressenti lorsque votre Société avait réussi à franchir cette première grande étape, rêve de toutes les Associations à leur début: la parution bi-mensuelle des annales et de la documentation.

Quel service votre Journal a ainsi rendu en augmentant sa périodicité!

J'en appelle au témoignage de tous ceux pour qui, comme pour moi, il a été un instrument de travail infiniment précieux, toujours attendu avec impatience.

Et maintenant, c'est la perfection même que vous allez atteindre en arrivant à l'étape dernière: celle de la parution hebdomadaire; ainsi se trouvera parachevée la belle oeuvre qui a été celle de la Society of Chemical Industry, cette oeuvre que vos amis français n'ont cessée d'admirer, et en même temps, je puis le dire, de vous envier.

Je ne puis mieux vous exprimer mon approbation qu'en vous disant: votre Société est pour nous un modèle; votre dernière initiative sera un stimulant puissant qui nous décidera à nous engager nous-mêmes dans la voie que vous nous tracez.

Vers cette voie tend depuis longtemps notre préoccupation constante; à votre exemple, nous nous y engagerons, je l'espère, avec la même volonté et la même énergie.

From

Sir James Walker, F.R.S.

President of the Chemical Society

The establishment of a new weekly journal of Chemistry which students, teachers and industrialists alike may read is an event certain to have most beneficial and far-reaching consequences.

The student with his antiquated text-books—all text-books are in reality antiquated—is only late, if at all, brought into touch with current scientific research through lectures and journals: the young research worker is too apt to become a premature specialist: the teacher, harassed by the work of instruction or administration, too readily loses heart before the accumulating pile of chemical literature. And if such be the case on the academic side, notable for its leisured ease, how must it be aggravated for the busy industrialist. Furthermore, the technical chemist has no time to make himself acquainted with what is going on in the domain of pure chemistry; and the academic chemist remains ignorant of technical advances for the same reason. Each branch of our science should serve as a stimulus and auxiliary to the other, and it is a chief function of the new journal to bring this to pass by publishing short readable articles on the things that matter in the chemistry of the day, whether pure or applied. Mutual knowledge is the basis for effective collaboration.

The generous offer made by the Society of Chemical Industry to the Chemical Society in respect to the first year's issue of the new weekly is welcome evidence of the spirit of co-operation that already exists between the Councils of these Societies, a spirit which *Chemistry and Industry* will, amongst the membership, do much to foster. It enters on its career with the good wishes of chemists of every occupation and every interest.

THE CALCIUM CARBIDE INQUIRY

SIR WILLIAM J. POPE

Part I

THE hearing of an application before a Board of Trade Referee early in 1922, for the inclusion of calcium carbide among the substances covered by the Safeguarding of Industries Act evoked a lengthy discussion of the definition of an organic compound; the learned Referee ultimately stated as his opinion that calcium carbide was properly excluded from the list of synthetic organic chemicals and the application accordingly failed.

The transcript of the shorthand notes shows that, from the standpoint of the chemist, the proceedings degenerated into an orgy of misapprehension and misinterpretation; commenting on the subject in a letter to the *Times*, I remarked that "owing to the fact that the Referee, himself a distinguished lawyer, has not been given the assistance of a chemist as assessor, these Board of Trade inquiries have become ridiculous farces played to the shame of British methods of legal procedure." Sir Arthur Colefax, one of the leading counsel engaged in the inquiry, is not convinced by my criticisms, which he says "are not well-founded and are ungenerous"; it seems therefore desirable that the grounds for regarding calcium carbide as a typical synthetic organic compound should be discussed in one of our technical journals.

The Definition of an Organic Compound

The modern and very precise meaning attaching to the term "organic compound" began to take shape at the overthrow of the Berzelius' assumption that "the elements present in living bodies obey laws totally different from those which rule inanimate nature." The intervention of a vital force in the formation of chemical products by living matter became superfluous and as Kekulé stated, "whilst, formerly, chemistry was divided because a boundary was seen, afterwards, such a boundary was looked for because it was found convenient to have one"—*Lehrbuch der organischen Chemie oder der Chemie der Kohlenstoffverbindungen*, 1859, vol. 1, page 8.

The new standpoint was given by A. Laurent (*Chemical Method, Odling's translation*, page 179).

1. "We maintain for our part, that an organic substance is simply a substance containing carbon; thus marble, cyanogen, carbonic acid, chloro-carbonic acid, etc. are organic substances. As on the one hand, cyanogen, carbonic acid and acetic acid can combine with all the metals and on the other hand, we have carbon compounds containing sulphur, selenium, chlorine, nitrogen, etc., it is clear that organic chemistry comprises, not only the combinations of carbon with hydrogen, oxygen and nitrogen, as is ordinarily stated, but also the combinations of carbon with all simple bodies whatever. Organic chemistry thus defined, or the chemistry of carbon, differs from mineral chemistry by the unlimited number of combinations which may be produced when but two or three simple substances are associated with carbon."

There is no ambiguity in this careful statement: every compound of carbon is an organic compound; but it only became the accepted definition after long and exhaustive discussion. Dumas never freed his mind from the definition of his youth (Faraday Lecture, *Chemical News*, July 2, 1869); Gmelin (*Handbook of Chemistry*, 1852, vol. 7, page 5), in objecting to the oxides of carbon being included among organic substances, referred to the then hypothetical, but now well-known oxalic anhydride, C_2O_3. Ultimately, however, every definition of an organic compound given by an acknowledged master of organic chemistry, in which modern knowledge disclosed no inconsistency, was found to conform very closely to that of Laurent. The following is a representative list of these definitions.

2. "We thus define organic chemistry as the chemistry of the carbon compounds."—A. von Kekulé, *loc. cit.*, page 11.

3. "Chemistry is the study of the atom; organic chemistry is thus that of the carbon atom . . . . organic chemistry has for its object not only the study of the compounds of carbon but also that of the element itself."—J. H. van't Hoff, *Ansichten über die organische Chemie*, 1881, vol. 1, page 1.

4. "Organic chemistry may be generally defined as the chemistry of carbon and its compounds, since carbon is the one essential element in all organic compounds."—H. E. Armstrong, *Organic Chemistry; the Chemistry of Carbon and its Compounds*, 1886, page 1.

5. "In order not to have to describe carbonic acid as an organic compound, L. Gmelin defined organic chemistry as the chemistry of those carbon compounds which contain more than one atom of carbon in the molecule. Wood spirit, CH_4O, and the formic acid, CH_2O_2, contained in ants would thus not be organic compounds. As is seen, this limitation cannot be retained and we must define organic chemistry as the chemistry of all the carbon compounds."—F. Beilstein, *Handbuch der organischen Chemie*, 1893, vol. 1, page 1.

6. "And organic chemistry becomes the chemistry of the carbon compounds."—J. B. Cohen, *Theoretical Organic Chemistry*, 1903, page 3.

7. "Organic chemistry is the chemistry of the carbon compounds—partly upon grounds of convenience, carbon itself and some of its principal compounds, such as carbonic acid, which is so widely distributed in the mineral kingdom, are treated of under inorganic chemistry."—A. Bernthsen, *Textbook of Organic Chemistry*, 1906, page 1.

8. "At the present day we mean by 'organic compounds' simply the compounds of carbon. . . . There is apparently no *a priori* reason why any element should not be associated with carbon, and enter into the composition of an organic compound."—T. E. Thorpe, *History of Chemistry*, 1909, vol. 1, page 128.

9. "Organic chemistry is hence the chemistry of the carbon compounds."—V. von Richter, *Chemie der Kohlenstoffverbindungen oder organische Chemie*, 1909, page 2.

10. "Organic chemistry, therefore, is the chemistry of the carbon compounds. Some of the simpler compounds of carbon, such as carbon dioxide and carbon monoxide, which are of general importance, are always described in works on inorganic chemistry for the sake of convenience; they are, nevertheless, organic compounds, because they contain carbon."—W. H. Perkin and F. S. Kipping, *Organic Chemistry*, 1911, page 3.

11. "Organic chemistry is the chemistry of the carbon compounds."—A. F. Hollemann, *Textbook of Organic Chemistry*, 1914, page 1.

12. "Organic chemistry is the chemistry of all carbon compounds; every carbon compound is, by definition, an organic substance." C. Moureu, *Fundamental Principles of Organic Chemistry*, 1921, page 2.

13. "The organic chemistry of to-day is a chemistry of the carbon compounds. . . . Organic chemistry embraces all the compounds of this element; only a few of the most simple—carbonic oxide, carbonic acid and its salts and certain compounds of carbon with other metalloids or metals (carbides) produced at high temperatures—are treated on grounds of expediency in inorganic chemistry."—V. Meyer and P. Jacobson, *Lehrbuch der organischen Chemie*, 1907, vol. 1, page 2.

The above definitions of the scope of organic chemistry are quoted from the writings of celebrated organic chemists who have spent their lives in developing their subject and who, in this occupation, have necessarily given profound attention to the meaning of the term "organic compound." These definitions agree that every compound of carbon is to be regarded as an organic compound but a few others, also of outstanding authority, have been designed for the express purpose of excluding carbon monoxide and dioxide from the class of organic substances; we thus have—

14. "We consequently define organic chemistry as the chemistry of the hydrocarbons and their derivatives."—C. Schorlemmer, *Lehrbuch der Kohlenstoffverbindungen oder der organischen Chemie*, 1897, page 7. Whilst this probably excludes carbon monoxide it includes carbon dioxide as a simple derivative of methane and is indefinite to the extent that it may be taken to exclude purine, as being too distantly derived from a hydrocarbon.

15. "The name organic is commonly restricted, by chemists, to compounds the molecules of which consist of one or more atoms of carbon *directly* combined either with carbon, nitrogen or hydrogen. Thus, according to this definition, carbonic anhydride and hydric potassium carbonate are mineral or inorganic compounds, because the carbon which they contain is directly combined with oxygen only."—E. Frankland, *Lecture Notes for Chemical Students*, 1872, vol. 2, page 1. This definition is faulty in that it excludes perchloromethyl ether, $(CCl_3)_2O$, from the category of organic compounds.

The following statement emphasises an aspect of the question which arose during the carbide enquiry:—

16. "The name chemistry of the compounds of carbon has been objected to as being too broad. Strictly speaking, this title includes the carbonates, and it is customary to treat of these widely distributed substances under the head of inorganic chemistry."—Ira Remsen, *The Study of the Compounds of Carbon or Organic Chemistry*, 1886, page 2. Although Remsen regards the carbonates as organic substances he notes that they are treated under the head of inorganic chemistry because their omnipresence makes them of interest to others than specialists in organic chemistry.

The situation may now be summarised as follows:—All definitions of an organic compound which have been given by organic chemists of repute and which have not become invalidated by modern knowledge agree in including the compounds of carbon generally; a small minority of such chemists exclude from their definitions, carbonic oxide, carbonic anhydride and the salts of carbonic acid with inorganic bases. No other compounds of carbon are excluded from the definition by any organic chemist of repute.

Statements discordant with the foregoing have, of course, been advanced; but these are not the production of organic chemists of repute or even of chemists who, by virtue of their devotion to original investigation, have had need to reflect carefully upon questions of definition. We thus have the following:—

17. "Indeed it may be said that no exact definition of an 'organic' compound has ever been framed, and we have to accept the general statement that 'organic' chemistry is the chemistry of the carbon compounds with certain generally acknowledged exceptions." G. S. Newth, *Textbook of Inorganic Chemistry*, 1903, page 296. The opening phrase of this statement is erroneous in view of the many exact and concordant definitions previously quoted; the fact that the writer has not been a contributor to organic chemical knowledge renders his statement of as little authority as those given by the dictionaries. *Lloyd's Encyclopædic Dictionary*, 1895, defines organic chemistry as "The chemistry of the carbon compounds in which the hydrogen or nitrogen of the substance is directly united with carbon"; this definition is clearly unacceptable because it excludes such organic compounds as tetrabromothiophene, croconic acid and perchlorobenzene. It is nearly as objectionable as the following:—

18. "In all organic compounds carbon and hydrogen appear as never-failing constituents."—E. P. Möller, *The Law of Atomic Linking*, 1895, page 4.

The wealth of available definitions, identical in purport, by outstanding organic chemists and the reason why no importance can be attributed to conceptions of an organic compound formulated by authors unknown to organic chemistry did not transpire during the calcium carbide hearing. The idea was promulgated that because a particular compound is treated in works on inorganic chemistry it is necessarily not an organic compound; this is, of course, absurd, for text-books on inorganic chemistry deal habitually with many well-recognised organic compounds. Thus, H. Erdmann in his *Lehrbuch der Anorganischen Chemie*, treats at length of the hydrocarbons methane, ethylene and acetylene and discusses the constitutions of the paraffin hydrocarbons in general; W. Ramsay, in his *System of Inorganic Chemistry* deals at length with methane, ethylene, acetylene and the organometallic compounds and Alexander Smith in his *General Inorganic Chemistry*, describes many hydrocarbons, acetic and oxalic acids, the starches and sugars, ethyl alcohol, ether, the soaps, drying oils, etc., and discusses in notable detail the constitution and behaviour of organic compounds. This is, of course, all in harmony with the definition, accepted by all the authorities, that organic chemistry is the chemistry of the carbon compounds; it is in recognition of the fact that the inorganic chemist in order to be efficient, must know something about organic chemistry, just as he must know something about the elementary laws of physics and something of elementary mathematics.

The most eminent organic chemist called in the hearing, Professor W. H. Perkin, was unshaken in his adhesion to the classical definition of an organic compound. The Referee was, however, much impressed by the fact that von Groth, who is not a chemist, describes the crystallographic properties of the carbides under an inorganic heading although he does not remark that the same author deals with many complex organic compounds under a similar heading. The Referee then quoted in his decision the following mistranslation of the definition by Meyer and Jacobson (No. 13 above)—"in Meyer and Jacobson it is stated that organic chemistry embraces all compounds of carbon except the simplest—viz., carbon monoxide, carbon dioxide and its salts, and certain compounds which arise at very high temperatures—viz., the carbides, which are usually dealt with in the inorganic branch on the ground of suitability." Meyer and Jacobson's definition includes carbon monoxide, carbon dioxide and the carbides as organic substances but the Referee translates it as meaning that these are not organic compounds. The bias arising from the mistranslation is reflected in the Referee's later observation, again in his decision, that—"The strongest statement in favour of the complainants is found in Richter, who says in terms that calcium carbide is organic, but he also says that carbon dioxide and carbon monoxide are organic, whereas it is conceded that they are not so regarded." The mistranslation of one authoritative definition is thus used to contradict the others. The Referee gathered the further erroneous impression that the expressions "compounds of carbon without exception," "hydrocarbons and their derivatives" and "compounds of carbon which contain an organic radicle" are so discordant as to justify him in concluding that "there is not a technical meaning of the words 'organic chemical' which has been generally accepted by chemists."

In a later communication it will be shown that calcium carbide is not only an organic compound but that it is a synthetic compound which is a simple derivative of the hydrocarbon acetylene and contains an organic radicle.

FROM THE TIMES 11th DECEMBER 1922

SAFEGUARDING OF INDUSTRIES ACT

To the Editor of The Times

Sir,—The debate in the Commons on the Safeguarding of Industries Act, 1921, showed that, whatever differences of opinion exist as to the wisdom of the measure, the attack upon it was advisedly based upon the manner of its interpretation rather than upon its spirit. The tactics of the Opposition were sound; probably few pieces of legislation have been so marred by faulty drafting of the explanatory schedule as has been that designed for the protection of the key industries.

Without discussing the whole of the schedule I would draw attention to its last paragraph, which describes as imported "goods chargeable with duty" the following:—

> All synthetic organic chemicals (other than synthetic organic dyestuffs, colours, and colouring matters imported for use as such, and organic intermediate products imported for their manufacture), analytical reagents, all other fine chemicals (except sulphate of quinine of vegetable origin) and chemicals manufactured by fermentation processes.

The chemical trade distinguishes between a "fine chemical" and a "heavy chemical," just as ordinary mortals distinguish a "heavy dog" from a "fine dog"; the really heavy or the really fine is unmistakable, but no definition of either can be given without prescribing numerical dimensions of heaviness or fineness in an entirely arbitrary manner. The introduction of the term "fine chemical" into the interpreting schedule is as direct an invitation to litigation as if statute exempted heavy dogs but charged 40s. for a licence to keep a fine dog; the legal profession has good reason to know that the invitation has been widely accepted.

Similar incompetence marks the drafting of other phrases in the schedule. To speak of "sulphate of quinine of vegetable origin" is as tautological as to specify mutton chops got from the sheep, because all sulphate of quinine is of vegetable origin; the expression "chemicals manufactured by fermentation processes" embraces unintentionally too wide a field, for it includes Chile nitrate and natural indigo.

But whilst the Government official who drafted the schedule has exhibited a marked talent for vague and inaccurate expression, the legal interpreters have shown him to be not without close competitors. Early in the year an application was heard before a Board of Trade referee for the inclusion of calcium carbide among the scheduled chemicals as belonging to the class of "synthetic organic chemicals"; the legal arguments turned largely on what is meant by an organic compound. Many definitions of an organic compound have been given by eminent organic chemists, and all, though different in wording, agree in stating that the term "organic compound" includes all the compounds of carbon.

The referee, in his decision, quoted a very carefully worded definition by a German authority, but quoted it in the form of a mistranslation which entirely altered its meaning; on this erroneous statement of fact, the referee rejected the application. Calcium carbide, one of the most typical synthetic organic compounds, is declared by the referee, on a false translation of a German definition, not to be an organic chemical.

The history of the calcium carbide inquiry has been repeated in connexion with many other applications concerning the interpretation of the schedule; in all, the definitions and facts of organic chemistry, one of the exact sciences, have been misinterpreted and remoulded in a manner which would have delighted Lewis Carroll. Owing to the fact that the referee, himself a distinguished lawyer, has not been given the assistance of a chemist as assessor, these Board of Trade inquiries have become ridiculous farces played to the shame of British methods of legal procedure.

William J. Pope

Cambridge, Dec. 8

FROM THE TIMES 16th DECEMBER 1922

SAFEGUARDING OF INDUSTRIES ACT

To the Editor of The Times

Sir,—If Sir William Pope had confined himself, in the letter which you published on December 11, to contending that the drafting of that portion of the schedule to the Safeguarding of Industries Act which he quotes is unsatisfactory, he would have found few, if any, of those who have had to consider the meaning of the expressions used therein in disagreement with him.

It should, however, I think, be recognised that it must have been a task of considerable difficulty to draft this portion of the schedule so as to carry out the policy of the Act; and, further, it should not be overlooked that, in respect of the list of many thousands of substances—being the Board of Trade's interpretation of such portion of the schedule—the applications for revision of such list which have been brought to a hearing number sixteen, and that probably not half-a-dozen more will be brought to a hearing. Sir William is on safe ground in his criticism of the expression "fine chemical." It lacks desirable precision. It is not a scientific term, and, as a trade term, it is of doubtful significance. His criticisms, however, of the "legal interpreters" and of "these Board of Trade inquiries" are not well-founded and are ungenerous.

There has been only one legal interpreter of the above portion of the schedule—a distinguished lawyer, as Sir William acknowledges. He was appointed, as provided by the Act, by the late Lord Chancellor, and, I suggest, is improperly described as "a Board of Trade Referee." I believe I shall have the consent of all who have been engaged in these hearings—whether as party, witnesses, or counsel—in maintaining that the learned Referee has discharged his difficult duties in a remarkably able, painstaking, and conscientious manner. When Sir William says that "owing to the fact that the Referee, himself a distinguished lawyer, has not been given the assistance of a chemist as assessor, these Board of Trade inquiries have become ridiculous farces, played to the shame of British methods of legal procedure," he appears to be unmindful of the fact that the learned Referee has had the duty, and has discharged it, of deciding the applications on the evidence before him. as also of the fact that such evidence has, in the main, been the evidence of chemists, not only fully qualified, but distinguished as such, although Sir William has not—and this is undoubtedly to be regretted—himself been a witness in any of the inquiries.

Sir William refers to, and apparently relies in support of the views expressed in the passage in his letter which I have quoted above, upon the calcium carbide application. He says that calcium carbide is one of the most typical synthetic organic compounds. He further says that all definitions of the expression "organic compound," given by eminent organic chemists, agree in stating that the term includes all the compounds of carbon. I, as counsel, was present throughout the inquiry, and heard the whole of the evidence. So far from all the chemists agreeing that the term "organic compound" includes all carbon compounds, all the distinguished chemists, whether eminent in organic or inorganic chemistry, who gave evidence excluded one or other carbon compound from the definition of "organic compound." Further, there was the sharpest division of opinion on the part of the chemists as to whether calcium carbide—which Sir William regards as one of the most typical synthetic organic compounds—was either a synthetic or an organic compound. On the evidence as a whole, and not on any isolated definition, such as Sir William says was mistranslated, the Referee decided the case, holding that the applicants had not established that calcium carbide was a synthetic organic chemical.

I submit that, had Sir William been better informed, he would have refrained from criticising these inquiries or their results, at any rate in language which does not bear the impress of that accuracy in statement or care in consideration which, in fairness to the learned Referee and those who have taken part in such inquiries, may reasonably be demanded.

Yours faithfully,
ARTHUR COLEFAX

The Temple

LEGISLATIVE AND DEPARTMENTAL INTERFERENCE WITH INDUSTRY AND THE COMMON WEAL*

By PROF. H. E. ARMSTRONG, F.R.S.

MILK

I begin with mother's milk. To what extent are chemists advising the mothers that milk is not made out of nothing and that inability to satisfy, if not to feed the child at all, more often than not is the mother's fault, due to the fact that she has been insufficiently and ineffectively fed, may be even in her own distant infancy? How many chemists pay any attention to the subject and can advise even their own wives?

Passing to the cow—we chemists have done an evil thing in connexion with cow's milk, in having been parties during nearly fifty years to an early abuse of the Food Adulteration Act, without ever seeking to remedy its consequences. When the Act became operative, some vendors were charged with watering milk, the ground being that the percentages of fat, etc., were below the imposed standard. Proof was given by not a few that there had been no watering; the milk was merely poor in quality. Instead of enforcing improvement of quality, the standard was lowered, I believe, to admit all natural milks; as a consequence, milk may be legally watered down to this standard. It is not possible to say to what extent, if at all, milk is now diluted; but it is well known that the large vendors standardise by mixing milks of all qualities and that no premium is placed upon the production of milk of high quality. As a consequence, the quality of the milk supply of large towns has in no way been improved in recent years, especially as no care is taken by most to mix the morning and afternoon milks, which are often very different in quality.

The matter has been left in the hands of the Public Analyst. The condition of affairs is well known, however, to the Board of Agriculture, to the Ministry of Health, to the Somerset House Authorities and to the Agricultural Societies; but neither the Government Departments nor chemists have yet had the wit to promote any improvement. Is it surprising that the public gain no faith in science, if science make no appearance, by coming forward in its protection, in so vital a situation?

Now a still worse thing is happening. The Ministry of Health, acting independently, if not against the Ministry of Agriculture, has secured the passing of a measure, to come into operation on January 1st, 1923, which will legalise the application to milk of an unnatural treatment known to have a most definite and, without hesitation be it said, detrimental effect upon its food value. So far as I have been able to discover, no attempt was made to discuss the possible effect of the measure in any proper scientific manner, to determine to what extent the supposed advantage of the treatment outweighs the disadvantages, known or conceivable; doubtless it was drafted to satisfy some popular cry and in accordance with the whim of one or more departmental experts.

---

* A paper read before the Nottingham Section on December 13, 1922.

The position is one of extraordinary difficulty. On all sides there is very properly an outcry for clean milk and the advance of knowledge is leading an increasing proportion of dairymen to do their best to meet the demand and produce milk of high quality; but the low standard to which I have referred is against advance; now there is danger, that this may be further checked by the operation of the new Act, as the Act provides a means, viz., heating, which it is assumed will render dirty, infected milk harmless, in the sense that it will not carry infectious disease.

In the later years of the war, when there was a shortage of milk, not a little that was known to be very dirty was *pasteurised*, by the vendors, to render it safe; the practice has grown apace, without the public being consulted or made aware of the change. It is stated that whereas in 1918 thirty per cent. of the milk sold in London was pasteurised, now up to eighty per cent. is so treated. Londoners, for the most part, are dealing with a whited sepulchre.

It is the old question, whether we should—

> "rather bear those ills we have
> Than fly to others that we know not of ?"

Conscience has made no cowards of the milk vendors; to serve commercial ends in the main, the trade is boldly, without permission asked, changing the character of our fundamental food, that upon which our infants and children are nourished. Their whole lives may be imperilled by this change: their growth stunted and their level of health lowered.

That milk is changed by heating above blood heat is certain—no one who has the slightest knowledge of the subject will deny this; the extent of the change, the number of factors affected, be they advitants or enzymes or unknowns of other kinds, is entirely unknown to us. All we can assert is, that being present in so vital a product—vital in the sense that it is made by the living for the living—it is unlikely that they should not each and all have their purpose and be essential to complete and healthy growth. Heated milk, we know, produces scurvy in sensitive animals and not infrequently in human infants; moreover, it is found that before the external symptoms of scurvy are apparent, the structure of the teeth is seriously affected; for all we know, there may be other effects not open to present observation, more or less deep-seated, even coming into operation later in life.

Why should we "denaturalise" our milk as we do spirit by methylating it? In the latter case, the object is clear and admitted; in the former, the object is definitely charitable but the result is possibly as uncharitable as that which is aimed at and secured in the latter.

The vendors aim at making the milk keep, *i.e.* at preventing it from turning sour, an almost natural change, which does not depreciate its dietetic value—as instanced by the advocacy and use of sour milk by the Metchnikoff school. In Denmark the desired result is secured by cooling. If the state of Denmark be not rotten in such respect, why should ours be? Why should we seek to kill when we can easily cure by simple means? Answer:—because we are a lazy and totally unorganised people, in the hands of an unthinking bureaucracy, without light of scientific method.

We are guided by science, may be the retort. Have we not a bacteriologist? have we not made experiments with guinea pigs? even with a monkey who was cured by heated milk? —as we were solemnly told at University College, London, a few days ago.

Due respect we must have for those fearsome wild fowl, the bacteria—but we need not bow down and worship them always, at the command of those who perpetually gaze upon them and have no time left for the exercise of a reasonable logic. The real issue is the "to be or not to be" of tubercular disease of bovine origin and on that the medical profession is in no way at one. The assumed risk is 6·5 per cent. of the total number of deaths from tuberculosis; the accuracy of the estimate is open to question but even if it be accepted, such a loss is small in comparison with the injury which may conceivably be wrought upon the population at large by denaturalising our primary food. The battle of life cannot be fought without loss by the way. We shall need to fight with hale forces in future; our population is at least double what our country can carry; it is desirable to eliminate the unfit. To-day we are forced to put sentiment aside; if we do not, the incidence of natural economic causes, if not sudden revolt, will bring about what we have not the sense to accomplish.

The bacteria themselves are against our stupid ways. They at once take advantage of the gaps we introduce to attack us. Nothing so predisposes to disease as insufficient and faulty feeding. This is particularly true of tubercular disease, the modern cure for which is a high diet and exercise in the fresh air.

You know the awful example held up in *Struwelpeter*:—

> "Augustus was a chubby lad,
> Fresh rosy cheeks Augustus had,"

until one day he began to damn his soup and refused to take it; thence-forward he languished and soon died.

Apparently the "soup" is, in some way taken from milk, when it is heated. The infant fed on dried milk, at first, is like Augustus—though only when coaxed with fruit juice, cold-drawn cod liver oil, etc., but in the second year is peculiarly susceptible to infectious disease. We have yet to write the after-history of its teeth and other delicate parts of its mechanism.

Up to within half a dozen years ago, the value of food was assessed upon a basis of calories—as if it were so much timber. It was recognised, that a certain ratio of fat, carbohydrate and protein was desirable ; but beyond this little real attention was paid to quality. The doctrine was long taught in the cookery schools, that the value of protein foods was to be reckoned in terms of nitrogen ; Emil Fischer's work made this view impossible. Then came the discovery of advitants—of a class of natural condiments in the absence of which from food,

"the hungry sheep look up and are not fed."

Three at least are recognised already ; there may be thirty for all we know, the inquiry is so new and so difficult. Some if not all, are very sensitive to change. Modern methods of preserving food, modern methods of cooking food—especially the substitution of baking for roasting, an unfortunate consequence of the use of gas stoves—seem all to favour this destruction. In some way our urbanized civilisation has gone astray, we know ; some explanation of our large C3 population has to be given—to say that faulty feeding is one of its great causes is no mere guess. Sir Arthur Keith tells us—"In olden days the teeth were often ground down to their sockets (which means that the food was uncooked) ; nowadays, even after sixty years of wear, we may observe *in such of them as have survived the modern disease of caries,* that their chewing surfaces are scarcely worn." It is significant, as I have said already, that before the external symptoms of scurvy are apparent, the structure of the teeth is adversely affected. Caries has been detected in Prehistoric Man, though in rare cases ; so the disease is not of modern origin ; as few now escape it, there must be some favouring condition at work and the indications are all towards our denaturalised diet, rather than to loss of an aforetime natural occupation. Quite a number of inmates of our asylums, we know, were done to death in all kindness by feeding them on food stewed so long that it was deprived of all "goodness," to use the popular phrase : of advitants, in our scientific jargon. The advitants apparently are vegetable products and are but passed on to the animal. We have yet to feed ourselves rationally. Abroad, no chief meal is served without some sort of green salad or fresh fruit ; here neither is thought to be a necessary regular article of diet.

(*To be continued*)

OBSERVATIONS BY "EYE-WITNESS"

"THE Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them."

The new guise in which the old Journal of the Society now makes its appearance affords an opportunity for a weekly comment on matters chemical which has hitherto been lacking. The expression of official policy which all editors are by reason of their position condemned to expound in editorial articles places a restraint upon them which makes for tranquillity but not always for progress. I am happy, then, to accept the Editor's suggestion that I should comment on the passing events in the chemical world, and where necessary ventilate those unorthodox opinions which it is the privilege of the extremely young and the very old to express.

Why are there so many Chemical Societies and Associations ?

This is one of the questions which is constantly in the minds of chemists and chemical industrialists, and even found expression in a speech delivered by the President of the Society of Chemical Industry a few weeks ago. There are a lot of them. They seem to have arisen because the older societies were unwilling or unable to broaden their bases and adapt themselves quickly to the changing needs of the times. But I am not convinced that there are too many societies. Man is a gregarious animal and the scientific variety of the species likes to congregate if a reasonable excuse can be provided for so doing. The numerous Societies provide the excuse ; they enable us to deceive ourselves into thinking we are performing serious duties, when in reality we are merely, but wisely, broadening our minds by mixing with our fellow-chemists. The real weakness of the numerous Societies is the lack of co-ordination—a blessed word.

What about the Federal Council ?

Whether the Federal Council can supply the missing adhesive depends on several factors. What is wanted is a body which by reason of its outstanding prestige, its single-mindedness and its known impartiality shall command the confidence of all the learned and semi-learned societies and associations. I suppose the Royal Society might have done the job if it had not been burdened with the weight of its own great prestige and its age-long traditions. What is wanted is a body which can unite the existing organisations in one representative whole. It must stimulate any society which is falling behind in the march of progress. It must, where necessary, promote the formation of new societies under its own ægis. It must even prevent the frivolous formation of a society which proposes to cover ground already covered by existing societies. This means a sinking to a small extent of the individuality which the societies overprize, and—be it whispered—the conversion of the permanent officials of the societies to a working together with other officials in a manner which is not always relished. I am all in favour of giving the Federal Council a chance. It is up to the members of its Council to justify the confidence they are receiving before they apply for a further instalment.

The Federal Council Applies for Funds

I was very glad to see that the Federal Council had issued an appeal for funds I shall send my mite a little later on. It is, of course, very right and proper that the first list should consist of contributions from those of our leaders who are willing to head the list with £50 notes. I am sure no one will criticise their generosity. In one way it shows the members of the Federal Council are prepared to dip into their pockets before searching other people's. I like the leaders who lead, but if the movement is to be a success it must be enthusiastically supported by the rank and file, and I would like to see a thousand one-guinea subscriptions and a similar number of half-guineas. That is the company with which I shall march.

Congratulations to Dr. Hodgkinson,

who has recently attained, so my newspaper informs me, the dignity of a Borough Councillor in Woolwich. My favourite reading nowadays is the newspaper, and an item of this description always catches my eye, possibly because it is so infrequent. I often wonder why so few of our scientific men take any active part in public life. Whatever the cause, the result is bad for science. The tendency of scientific men to become absorbed in their own subject is responsible in a large degree for the public attitude of indifference which characterised this country up to the time of the war and which will again become prevalent unless a greater number of scientists are prepared to engage in public work. I looked through the published list of members of Council; how few of them are in the public eye as they ought to be. Sir William Pope? Yes, and his scientific work and reputation has not suffered by it. The same applies to Sir Max Muspratt and Dr. E. F. Armstrong; but they are engaged in industry. Mr. Woolcock, of course, does not even pretend to more than a speaking acquaintance with the subject. But what about the others? Ought not they to follow in Dr. Hodgkinson's footsteps?

Chestnuts

I saw another interesting announcement in another of my newspapers to the effect that five thousand tons of chestnuts were among the cargo of the White Star liner *Homeric* when she sailed from Southampton for New York the other day; this is in addition to the quantity taken back personally by Dr. Ellwood Hendrick. This news will cause a sigh of relief from those of us who have to listen to so many after-dinner speeches at chemical functions. Let us hope that the next crop may exhibit the fruits of much research and careful fertilisation before they are produced for our delectation. I asked one of our most prolific talkers how he managed to use the apposite but somewhat aged stories with which he is accustomed to embellish his post-prandial oratory. He told me that he thinks of a story and then fits his speech round it. Very much like the man who used to pay the butler to slam the door as he left the room and then began: "Was that a gun? It reminds me once I was shooting in Burmah . . ."

Dr. M. O. Forster

Which reminds *me* that a friend of mine showed me a letter from our old friend Forster, who has now taken up his quarters in Bangalore. He seems from his letter to have had a delightful and profitable voyage—bridge was played. The Indian Institute of Science has over 300 acres, two to three miles out of Bangalore, and a large rectangle about half a mile long and a quarter of a mile wide has been reclaimed from the jungle and converted into a sort of garden city. In the middle are the library and offices, an imposing and spacious building with a tower, and at intervals round three sides of the rectangle are the hostel, the laboratories and the staff-bungalows, all built very substantially of local stone. I am sure we all wish Dr. Forster good fortune and hope we shall hear more of him from time to time.

A STIMULUS TO CHEMISTRY IN AMERICA

The Journal of Industrial and Engineering Chemistry recently published a letter from the Allied Chemical and Dye Corporation offering an annual prize of twenty-five thousand dollars to reward the chemist, residing in the United States, who in the opinion of a properly constituted jury has contributed most to the benefit of the science and the world. A committee is to be appointed to consider and suggest the rules governing the selection each year of the chemist who is deemed most worthy.

We comment on this interesting announcement in our editorial columns.

NEWS FROM THE SECTIONS

EDINBURGH AND EAST OF SCOTLAND

The third ordinary general meeting of the present session was held jointly with the Royal Scottish Society of Arts, the Glasgow Section of the Society of Chemical Industry and the Edinburgh Section of the Institute of Chemistry in the Hall of the Royal Scottish Society of Arts in Edinburgh on December 11. Dr. T. W. Drinkwater, vice-president of the Royal Scottish Society of Arts, presided over a large attendance including twenty-two members of the Glasgow Section of the Society of Chemical Industry, and Prof. H. S. Allen read a paper on "Modern Theories of the Structure of the Atom." In reviewing the present state of knowledge regarding the atom from the arithmetical, geometrical, and dynamical points of view, Professor Allen referred to the researches of Sir J. J. Thomson, Mr. C. T. R. Wilson and Sir Ernest Rutherford, and to the theory of atomic numbers advanced by Moseley. Greatly as the chemical balance had enabled the chemist to add to our knowledge, the gold-leaf electroscope had proved an even more powerful instrument of research in the hands of the physicist. The work of Sir William Bragg and Prof. W. L. Bragg on crystal structure was discussed, and also the theories of Professor Bohr, Professor Lewis, and Dr. Irving Langmuir, whose exposition at the Edinburgh meeting of the British Association was recalled. Magnetic theories of the atom had been advanced by Parsons, Sir Alfred Ewing, Principal Laurie and Professor Whittaker. After mentioning the researches of Professor Barkla, Professor Soddy and Dr. Aston, all Nobel prize-winners, the lecturer referred to Sir Ernest Rutherford's remark that the study of the nucleus of atoms might profitably be left to the next generation, but added that Sir Ernest had since tackled this problem himself. The lecture was illustrated with models and lantern slides and was followed by a discussion opened by the chairman, other speakers being Professor Caven, Glasgow, Dr. Cranston, Glasgow, and Messrs. Winklow and J. A. Watson, Edinburgh.

GLASGOW SECTION

The third meeting, held at Edinburgh on December 11, was the first of the joint meetings of the Scottish Sections; and, judging from the number travelling from Glasgow, it would seem that the proposal to hold joint meetings has been received favourably by the members.

The fourth meeting was held in the Institute of Engineers and Shipbuilders, Glasgow, on December 14, when Dr. Knox read a paper on "Nitrogen Fixation."

In his introductory remarks, Dr. Knox briefly reviewed the development of the nitrogen industries and explained that owing to recent economic conditions no comparison of costs would be made. Short accounts were given of the main features of the arc process, the manufacture of cyanamide, and the production of synthetic ammonia as well as its subsequent oxidation to nitric acid.

Arc Process.—The manufacture of nitric acid by the direct oxidation of atmospheric nitrogen involved the use of cheap electrical power, and the main reactions were the production of nitric oxide and its oxidation to nitrogen peroxide. The chief drawbacks in the process were the low electrical efficiency, and the necessity of providing a large absorption plant. Mention was made of the Häusser process, which was still in the experimental stage.

Calcium Cyanamide or "Nitrolim" was manufactured by causing nitrogen, obtained from liquid air, to react with calcium carbide at the temperature of the electric furnace. The product of such a reaction could be used as a fertiliser, for the production of ammonia, or for the production of low-grade cyanides. Reference was also made to Bücher's process for producing cyanides from sodium carbonate and the nitrogen of producer gas at a temperature of 900° C. in presence of iron as a catalyst.

Synthetic Ammonia.—The Haber process, in which atmospheric nitrogen combined with pure hydrogen at a temperature of 600° C. in presence of iron as catalyst and a promoter, the exact nature of which was a trade secret, was outlined. A modification of the process had been introduced by Claude, who utilised a pressure of 1000 atmospheres, thereby greatly reducing the size of the plant required. The ammonia so prepared could be oxidised catalytically to nitric acid. In conclusion attention was drawn to the fact that, compared with other countries, Britain was not paying sufficient attention to this important industry.

An interesting discussion followed, in which Mr. J. H. Young stated that, in 1913, he had prepared cyanides by a method similar to that published by Bücher, four years later, in 1917.

MEETINGS OF OTHER SOCIETIES

CHEMICAL SOCIETY

Two papers were read at the meeting of the Chemical Society on December 21, Sir James Walker presiding:—

"Benzbisthiazoles, Part II," by S. R. H. Edge; "Ring Chain Tautomerism, Part IV—The Effect of the Methyl Ethyl Grouping on the Carbon Tetrahedral Angle," by J. F. Thorpe and B. Singh.

The names were submitted of 92 candidates for election to the Society.

INSTITUTION OF CHEMICAL ENGINEERS

The fifteenth meeting of the Provisional Committee was held on December 6 at 166, Piccadilly, London, W., Sir Arthur Duckham presiding.

The hon. treasurer's report revealed the fact that the balance at the bank and in hand was £27 18s. As this sum will be insufficient to carry the Institution forward to the time when the first Council is elected, the hon. treasurer was requested to ask subscribers for a second instalment of their donations. The solicitor's report stated that the Board of Trade had announced that the licence had been granted and would be issued in a few days. A hearty vote of thanks was passed to Mr. Bonus for his work as solicitor.

A report was submitted on the work of the Selection Committee, and further names were put forward of gentlemen who were qualified for membership and associate-membership. The Selection Committee stated that many applications were held in abeyance until they could be dealt with by the first Council, when formed.

INSTITUTE OF CHEMISTRY

The Huddersfield Section held a meeting on November 24 jointly with the Huddersfield Engineering and Textile Societies, the local Section of the Society of Dyers and Colourists, and the West Yorkshire Metallurgical Society.

Dr. H. T. Calvert, of the Ministry of Health, addressed a large meeting on the subject of "Water for Industrial Purposes, with Special Reference to Textile and Engineering Needs." Dr. Calvert observed that water is the most neglected of the raw materials of industry, and pointed out that local sections such as those of the Institute of Chemistry, should be of great value in educating local manufacturers to realise that trained men are available to attack with every prospect of success the industrial problems which present themselves daily. Dr. Calvert proceeded to give an account of the sources of our water supply and the origin of the various impurities, including the various forms of life which may so multiply as to become the cause of considerable trouble.

"First secure your water" is a good maxim to adopt, for by suitable treatment it is technically possible to render any water suitable for any particular purpose. The practicability is largely a question of local conditions and expense.

The storage of water and its purification were dealt with systematically. For the textile industries a purer water is generally required than for the engineering industries, or rather, a purer water is usually obtained because the damage caused by unsuitable water is more immediately evident. The processes used for potable water, generally find application in the industries some five or ten years later. Amongst these processes in increasing order of cost are:—(1) Sedimentation; (2) chemical precipitation or coagulation followed by sedimentation; (3) filtration; (4) sterilisation. Of these, the last has at present a very limited application in industry in this country, though perhaps it will be generally adopted when it is realised how many faults and defects in the finished products are due to moulds and bacteria present in the raw water used in the processes.

THE OPTICAL SOCIETY

At the meeting held at the Imperial College on December 14, Sir F. W. Dyson presiding, the following papers were read:

(1) "A Large Aperture Aplanatic Lens not Corrected for Colour." (2) "The Optical Cosine Law." By T. Smith, M.A. (1) A lens suitable for spectroscopic work with aplanatic corrections for all zones may have as large an aperture as f/1 or still greater, all the surfaces being strictly spherical. An actual lens made by Messrs. Ross, Ltd., of 3-in. aperture possesses corrections comparable with those given by the theoretical investigation. With a slightly reduced aperture, correction for colour may be obtained without prejudice to the quality of the spherical corrections. The investigation shows that the production of suitable glass discs is the outstanding difficulty in the way of great increases in the relative apertures of telescope objectives. (2) The law of refraction, the sine law relating to coma, and other exact laws of optical instruments are particular cases of a very general law which assumes the form of a cosine relation. As an example of the application of the law, the principles which should govern the construction of a variable power telescope yielding aplanatic correction at all magnifications are investigated.

(3) "A Constant Bubble." By S. Weston. A difficulty always encountered in an accurate spirit level of the type usually mounted on surveying instruments is the alteration of the length of the air bubble due to variation of temperature. This difficulty has been entirely overcome in a new type of level. The first consideration in the manufacture of such a bubble is to obtain the exact proportion of air and spirit. The cross-section of the tube containing the liquid is so shaped that as the temperature rises and the surface tension gradually decreases only the cross-sectional area of the bubble is affected, its length remaining unaltered.

Demonstrations were also given by Dr. J. S. Anderson on (1) a method of measuring the internal diameters of transparent tubes; and (2) a differential refractometer.

PERSONALIA

Mr. W. R. Cooper has been appointed editor of *Science Abstracts*.

Dr. R. C. Farmer has rejoined the Research Department of the War Office as Deputy Director of Explosives Research.

The President of the Board of Trade has appointed Captain G. E. W. Bowyer, M.C., M.P., to be his Parliamentary Private Secretary (unpaid), and Captain V. A. Cazalet, M.C., to be an Assistant Private Secretary (unpaid).

Dr. W. Rosenhain, superintendent of the Metallurgy Department of the National Physical Laboratory, will leave England in February for an extended tour in the United States, where he will lecture on metallurgical subjects before various universities and educational organisations.

The list of New-Year Honours includes the names of Sir Frank Baines, C.B.E., M.V.O., who is appointed a Commander of the Royal Victorian Order (C.V.O.); Dr. D. O. Masson, professor of chemistry in the University of Melbourne, who is promoted to a knighthood of the Order of the British Empire (K.B.E.), and Dr. J. W. Evans, F.R.S., representative of the Colonies on the Governing Body of the Imperial Mineral Resources Bureau, who has been appointed a C.B.E.

Awards recently made by the Society of Engineers for papers read or published during 1922 include the president's gold medal to Dr. C. V. Drysdale for his paper on "The Testing of Small Electrical Plant," the Nursey premium to Dr. H. Chatley for his paper on "The Physical Properties of Claymud," a Society premium to Mr. A. S. E. Ackermann for his paper on "The Physical Properties of Clay," and the Green premium to Mr. A. G. Short for his paper on "Heating."

* * *

The death is announced of Mr. A. W. Phillips, president and general manager of Dewis Chemical Products, Inc. (U.S.A.), and known for his work on the production of smokeless powder.

From France the death is announced of Monsieur E. Bouty, professor of experimental physics at the Sorbonne, and editor of the *Journal de Physique*, and of the *Annales de Physique*.

NEWS AND NOTES

UNITED STATES

Silica in 1920

The United States Geological Survey reports that sales of silica in the United States during 1920 totalled 328,740 short tons, valued at $3,152,734, and comprised 68,190 t. of quartz, 1,183,014 t. of sand and sandstone, 569,677 t. of tripoli, and 1,079,693 t. of diatomaceous earth. An increase of 8 per cent. in quantity and a decrease of 14 per cent. in value were shown by the sales of quartz, pegmatite and quartzite.

Quicksilver in 1920

The progressive decrease in the output of mercury in the United States that has been recorded since 1918 by the U.S. Geological Survey (*cf.* J., 1921, 310 R), continued in 1920 and by the end of the year all the mines except the New Almaden (California) and Chisos (Texas) mines had suspended operations. The output from 17 mines was 13,392 flasks (flask=75 lb.), valued at $1,066,807; not only was this the lowest recorded since 1860, but an even lower production was anticipated in 1921, possibly less than in 1850 (7723 flasks), the year when production first became important. This decrease is due to the fact that the ores now available in the United States are mostly too low in grade for profitable working. For this reason and because of the high exchange value of the dollar, exports fell by 7614 to 1553 flasks and imports rose by 3534 to 14,169 flasks. The apparent consumption was 26,008 flasks, an increase over that in 1919, but smaller than in 1917; the demand, however, was small towards the end of the year and manufacturers of mercurial products apparently held large stocks.

FRANCE

Eirini-d'Eyrinys, a Forgotten Predecessor of Pasteur

In the issue of the *Chemiker-Zeitung* for November 28, 1922, M. A. Rakusin draws attention to one of the appendices to the Russian translation of Sporny's treatise on "Asphalt and Bitumens," published in 1878. This appendix, of which the original source is not indicated, consists of a dissertation by a French physician, Prof. Eirini-d'Eyrinys, and describes the results of experiments on the disinfecting and prophylactic properties of asphalt, carried out in the year 1721 in the Hôtel des Invalides. In it the view is expressed that epidemic diseases are caused by "an immense number of invisible infusoria" which propagate with great rapidity and are transmitted from place to place on clothing, etc. Further, it is stated that the experimental results obtained show that either the oil isolated from asphalt or the fumes of burning asphalt will exterminate worms, bugs, etc., remove stench and purify the air, and disinfect clothing and other articles which have been in contact with persons suffering from plague, furniture and metallic objects remaining unharmed. The investigations were prosecuted at the instance of Le Blanc, then the French Minister of War, and it is possible that a complete account of it is to be found in the archives of the Invalides. Although Pasteur discussed the achievements of his predecessors up to the time of van Helmont in detail, he made no mention of Eirini-d'Eyrinys in his classical communications to the French Chemical Society in 1859 and to the Académie des Sciences in 1860.

Pasteur Celebrations

Prior to the celebration of Pasteur's centenary in May, 1923 (*cf.* J., 1922, 111 R), meetings in his honour will be held in this country from February 2 to 19, 1923, under the auspices of the Federated Committees of the Alliance Française in the United Kingdom. The hon. secretary of the Federated Committees, Mlle. Yvonne Salmo, of 14, Morgan Road, Reading, informs us that Dr. Pasteur Vallery-Radot, the grandson of Pasteur, will deliver a lecture on his grandfather's life and work in the rooms of the Royal Society of Medicine, London, and this will be followed by a banquet which will be attended by members of that Society and of the Institute of Brewing, and to which it is proposed to invite members of the various chemical societies. M. René Vallery-Radot will come to London, but his health will not permit him to go to the provinces, where Dr. P. Vallery-Radot will visit Manchester, Newcastle, Bradford, Liverpool, Cardiff, Reading, Leicester, Wolverhampton, Southampton, and Portsmouth (Feb. 19). In each of these towns the local branch of the Alliance Française is inviting the medical and chemical societies to take part in the proceedings. The Lord Mayor of Cardiff will extend a civic welcome to the visitors, and at Newcastle-on-Tyne Sir Theodore Morison will offer the hospitality of Armstrong College.

GERMANY

The Crisis in German Research Laboratories in 1922

Prof. A. von Wassermann, Director of the Kaiser-Wilhelm Institute for Experimental Therapy in Berlin-Dahlem, has recently discussed in a lecture the crisis that has arisen in the financial affairs of German scientific institutions. He said that, owing to the enormous depreciation of the currency, most of these places were on the brink of ruin, especially those engaged in experimental research. What a disaster the closing, through lack of funds, of any of these institutes would be to Germany, could easily be understood, when it was remembered that progress in all branches of natural science depended on experimental work, and that each branch was more or less dependent on others. Thus, medicine is dependent for its advancement on physical chemistry, especially on the colloidal branch of that science. He compared the interdependence of the sciences to the mechanism of a clock, which is completely put out of gear when one wheel is stopped, and stated that the work of the institutes was being hindered by the inability to purchase new instruments and material, as well as by the impossibility of obtaining foreign literature owing to its high cost in marks. The layman was reminded that biological research had an important bearing on public health; for example, experimental research on syphilis during the last 18 years had rendered possible a sure diagnosis, and produced cures for and protection against the disease, results which 500 years of careful observation had previously failed to produce. In the cure of other diseases due to specific bacteria success had also been obtained, and further advancement was possible only if the work of scientific research could be carried on uninterruptedly. It should be remembered that the ultimate aid of all reasearch was to produce, not only academic, but principally practical results and that, for this reason, all modern clinics and hospitals of any importance maintained their own bacteriological, chemical and X-ray laboratories, which were ever working in the service of the sick. Everyone should therefore realise, he said, what it would mean if these laboratories were unable to obtain the necessary means for carrying out their work, for not only would all research activity cease, but a retrograde step would be taken in the task of alleviating and curing the sufferings of mankind.

GENERAL

Federal Council for Pure and Applied Chemistry

The constituent societies of the Federal Council have appointed the following as their representatives on that body:—

Chemical Society:—Sir Wm. J. Pope, K.B.E., F.R.S.; Prof. J. C. Philip, F.R.S.; Prof. J. F. Thorpe, F.R.S.

Society of Chemical Industry:—F. H. Carr, O.B.E.; W. J. U. Woolcock, O.B.E.; Dr. Stephen Miall.

Association of British Chemical Manufacturers:—Dr. E. F. Armstrong, F.R.S.; E. V .Evans, F.I.C.; Dr. P. C. C. Isherwood.

Society of Public Analysts:—Dr. S. Rideal.

Faraday Society:—W. R. Cooper.

Biochemical Society:—Dr. J. C. Drummond.

Institute of Brewing:—A. Chaston Chapman, F.R.S.

Society of Dyers and Colourists:—C. F. Cross, F.R.S.

Society of Glass Technology:—Dr. W. E. Turner.

Iron and Steel Institute:—Sir Robert Hadfield, Bart., F.R.S.; F. W. Harbord.

Ceramic Society:—Dr. Mellor.

Institute of Chemistry:—Sir Herbert Jackson, K.B.E., F.R.S.

Institution of Gas Engineers:—Dr. H. G. Colman.

Society of Leather Trade Chemists (British Section):—J. T. Wood.

Mineralogical Society:—Dr. G. T. Prior, F.R.S.

Institute of Metals:—Sir Thomas Rose.

Royal Agricultural Society:—Dr. J. A. Voelcker.

Co-opted Members:—Dr. M. O. Forster, F.R.S.; H. E. Coley.

The Toxic Action of Cyanamide

It has been found that persons working with cyanamide are liable to fleeting exanthemata of the head and chest, accompanied by rapid breathing, increased action of the heart, and low blood-pressure, the attack lasting about an hour. The attack only comes on when the patient has consumed alcohol, so that persons working with the fertiliser should abstain from alcoholic drinks. The effect is due not to the toxic nature of the cyanamide, but to its power of energising the action of substances such as chloral hydrate, sodium bromide, theobromine, etc. Thus a man who took a dose of cyanamide in the morning and a glass of beer in the evening developed typical symptoms, the attack lasting six hours. Similarly, if a guinea-pig be given a physiologically inactive dose of sodium bromide, and a subsequent dose of cyanamide, symptoms of acute bromide-poisoning are immediately observed. —(*J. Ind. Hygiene, Sept.*, 1922.)

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for December* 21 *and* 28)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Algiers	Chemicals	716
Argentina	Glazed tiles	692
Australia, New Zealand	Tinplate, enamelled ware	662
Bulgaria	Porcelain insulators	9550/F.E./E.C.
Canada	Epsom salts	10169/E.D./E.C.
Chile	Ingots of antimony, tin, lead and zinc, pig iron, coke (tender for)	6858/F.L./E.C.
,,	Iron, steel, brass, paint, varnish (tender for)	7204/F.L./G.P.
Egypt	Oils, paint, asbestos, chemicals (tender for)	9621/F.E./G.P.
Egypt, Sudan, Palestine	Washing blue, starch	714
Italy	Paper, electric lamps	673
Netherlands	Iron, steel, non-ferrous metals	677
,,	Cottonseed oil	699
,,	Tin, tin foil	702
,,	Tinplate	703
New Zealand	Celluloid goods	666
,,	Druggists' supplies	670
Poland	Emery, sand paper	679
,,	Leather	681
Spain	Pitch	708
Spain, Portugal	Tinplate, tin, earthenware, copper sulphate	662
Switzerland	Paper, cardboard	686
,,	Leather, artificial leather	712
United States	Glassware, pottery	687
,,	Chemicals, colours, oils, wax, minerals	717
,,	Druggists' supplies	718
Yugoslavia	Tin	682

TARIFF CUSTOMS EXCISE

Austria—Czechoslovakia.—The commercial convention between these two countries came into force on November 14, 1922.

Canada.—Proprietary medicines must be provided with a label bearing the registered number of the medicine, the name and address of the manufacturer, and the proportion of any scheduled drug or drugs contained in the medicine.

Federated Malay States.—A list of export duties on rubber and of import duties on alcoholic liquors is given in the issue for December 21.

France.—A Bill has been introduced to modify the "turnover" tax and abolish the import tax.

Germany.—An import licence is required for foods (fruits, etc.) prepared with sugar. The export of composition wax is prohibited save under licence.

Greece.—The prohibition on the importation of "luxury" articles has been withdrawn, and the "coefficients of increase" applied to the duties on petrol, chocolate, white metal, etc. have been modified.

Grenada.—Additional export duties have been applied to cotton, cottonseed, and cocoa.

Guadeloupe.—The text of the regulations controlling the importation and sale of poisons may be consulted at the Department.

Norway.—Spirits and strong alcoholic liquors containing over 14 per cent. of alcohol by volume may be imported only through the A./S. Vinmonopolet.

Poland.—Salts and compounds containing gold, silver and platinum, organic compounds of iodine, certain compounds of mercury and of bismuth, synthetic organic colours, pigments, and varnish have been added to the list of goods the duties on which are subject to a surtax of 149,900 per cent. when paid in paper money.

Russia.—Regulations have been issued defining the procedure for importing and exporting goods.

Straits Settlements.—The new export duties proposed for rubber and the revised import duties on alcoholic liquors are detailed in the issue for December 21.

REPORTS

Report on the Economic and Financial Conditions in Venezuela, Dated September, 1922. *By* H. H. D. Beaumont, *H.B.M. Minister, Caracas. Pp.* 40. *Department of Overseas Trade. London: H.M. Stationery Office*, 1922. *Price* 1s.

Since the publication of the last report on Venezuela (*cf.* J., 1922, 14 R), the trade depression has not lifted, but the gradual exhaustion of stocks of imported goods is considered a more hopeful sign. Exports of sugar (refined and unrefined) in 1921 amounted to 13,782 tons, valued at 5,299,472 bolivars, against 18,811 tons, valued at bs. 17,920,272 in 1920, and it appears that in future the sugar industry will hardly be able to compete in the world's markets. The exports of hides and skins decreased from 2242 tons (bs. 6,022,059) in 1920 to 1127 (bs. 1,012,751) in 1921. Exports of balata were 979 tons in 1921, as compared with 1412 tons in 1920; prices at present are very low. The Caribbean Petroleum Co. remains the only oil-producing firm, and has now reached the profit-earning stage; its output rose from 69,539 tons of crude oil in 1920 to 218,246 t. in 1921, a year when 183,949 tons were exported. Exports of gold in 1921 increased by 4370 oz. troy to 30,257 oz., and of asphalt by 24,243 t. to 46,165 t. Owing to a fire in two of the most productive seams, and to labour difficulties, the production of coal fell by 7000 tons to 22,094 tons. Successful experiments have been made with briquettes, which are produced on a small scale. Only 11,323 tons of copper ore was mined by the South American Copper Syndicate in 1921, 6422 tons being exported; a smelting plant is now being erected at the mines.

Exports during 1921 totalled bs. 133,559,884 in value (the value of the bolivar during this period averaged 10·3d.; par value = 9·5d.), the United States taking 39·7 per cent., Holland and Curacao 22·9 per cent., Spain 11 per cent., France 9·1 per cent., and Great Britain and Trinidad 9·0 per cent. Of the imports, valued at bs. 95,508,367, the United States supplied 57·5 per cent. and Great Britain 18·7 per cent. Among the chief imports were:—Cement 10,222 tons (bs. 1,356,000); drugs 331 t. (bs. 2,379,000); perfumes, soaps, etc. 151 t. (bs. 1,004,000); skins 70 t. (bs. 979,000); and stearin 414 t. (bs. 561,000). The total value of the trade decreased from about £23,644,000 in 1920 to £9,433,000 in 1921; but whereas in the former year imports exceeded exports by £7,708,000, in 1921 the exports were the larger by £1,629,000.

REVIEWS

The Chemical Engineering Catalog. *Seventh annual edition. Pp.* 1183. *New York: The Chemical Catalog Co., Inc.*, 1922. *Price* $10, *or on loan for one year* $2.

The seventh edition of this volume fully maintains the standard of quality of its predecessors. The size is a little reduced but its 1100 odd pages (8½ x 11½ in.) fulfil the declared purpose of providing "a direct, permanent and economical information system, completely covering the entire worth-while buying power of the Chemical Industries of U.S.A."

The volume is published under the supervision of a committee appointed by the American Institute of Chemical Engineers, the American Chemical Society and the Society of Chemical Industry. No matter is passed for publication which is merely display advertising, but those taking space are expected to give data, facts, suggestions and details of application to specific technical and scientific problems. The present volume shows a distinct advance in the quality of the information supplied by advertisers.

A most useful feature is the classified directory of plant and materials which is amply cross-indexed and is primarily a record of manufacturers and their exclusive agents; it includes many firms who have not taken space in the catalogue. The plant and equipment section, which forms the body of the compilation, is well filled with illustrations and diagrams which help materially in showing what plant is available, data as to materials treated, processes catered for; overall sizes, power consumption, etc. form a prominent feature.

It has been recognised that chemical engineers and others in charge of production are responsible not only for the specifically chemical equipment, but also for the power plant, hoisting, conveying and power-transmission equipment, not to speak of testing, measuring and recording apparatus and materials of construction. The corresponding manufacturers are consequently well represented in the catalogue. On the average each has about 1·8 pages, but many have far more, one firm taking 66 pages. The section on chemicals and materials is not so large and on the average fewer data are given. Nevertheless, in many cases average analyses appear, together with specific gravities, melting-points, technical applications, and details of standard containers.

An index of some 1200 technical and scientific books is a helpful feature and there is a good synopsis of each work indexed.

Such a compilation is excellent advertising for American industry and must be specially helpful to its export trade. Can our own industry afford to ignore the possibilities latent in co-operative advertising of this nature?

E. A. A.

MARKET REPORT

This Market Report is compiled from special information received by the Society from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The condition of this section is practically the same as reported last week. An advance is recorded in the price of **Sodium Acetate** 97/98% to £23 per ton. Quotations for products not reported last week are as follows :—

Nitric Acid 80° Tw. ..	£25 per ton.
Sulphuric Acid 94% arsenical	£6 10s. per ton.
Potassium Bichromate	6¼d. per lb. delivered.
Salammoniac ..	£32 per ton delivered.
Sodium Nitrite ..	£30 per ton, 100% basis, delivered.
Sodium Sulphite, anhydrous for home consumption.	
5 ton lots ..	£27 10s. f.o.r. London.
2 ton lots ..	£28 f.o.r. London.
1 cwt.	drums included.

WOOD DISTILLATION PRODUCTS

Acetic Acid and **Acetone** have for some time past been the outstanding features of this section, supplies of the latter being particularly scarce. The price of the British Standard Specification is about £130 per ton. With regard to other products trade generally shows signs of improvement, but orders are rather difficult to obtain on pre-war quantities. Quotations for the principal products in this section are as follows :

Acetate of Lime, Brown	£8 per ton delivered.
Acetate of Lime, Grey 80% ..	£14 per ton delivered.
Acetate of Lime, Liquor	9d. per gall. 32° Tw. delivered.
Brown Sugar of Lead	£35 per ton delivered.
Charcoal	£9 10s. to £10 per ton.
Iron Liquor ..	1s. 6d. 32° Tw. 1s. 2d. 24° Tw.
Red Liquor ..	1s. 3d. 14/15° Tw.
Wood Creosote ..	2s. 6d. per gall. unrefined.
Wood Naphtha, Miscible	5s. per gall. 60% O.P.
Wood Naphtha, Solvent	4s. 6d. per gall. 60% O.P.
Wood Tar	£4 per ton delivered.

TAR PRODUCTS

Very little change is to be reported in this branch, The weakness of **Pitch** has proved to be only temporary, as was expected in view of the small amount available, and the position is again firmer. An improvement is also reported in the markets for **Toluol** and **Solvent Naphtha.** Current prices may be judged by the following quotations :—

Benzole, Crude 65's	1s. 2d. per gallon.
Benzole, Standard Motor	1s. 11d. to 2s. per gallon.
Benzole, Pure ..	2s. to 2s. 6d. per gallon.
Toluol 90% ..	1s. 10d. per gallon.
Toluol, Pure ..	2s. per gallon.
Xylol	3s. to 3s. 4d. per gallon.
Creosote, Standard Specification ..	7d. to 8d. per gallon.
Naphtha Solvent 90/160	1s. 8d. to 1s. 9d. per gallon.
Naphthalene Crude, drained Creosote Salt	£5 to £7 per ton.
Napthalene, Crude, hot pressed ..	£9 per ton.
Naphthalene, Crystals	£16 per ton.
Naphthalene, Flaked	£14 10s. per ton.

DYESTUFFS INTERMEDIATES

The tendency of dyestuffs prices to fall seems to have been arrested and business is reported to be fairly good with orders being placed for larger quantities. Trade is bound to be quiet, however, until after the holidays, but a further improvement is confidently anticipated in the New Year.

Manufacturers' quotations for the chief intermediates are as follows, prices being carriage paid and inclusive of packages.

Acid H.	5s. 4d. lb. 100% basis.
Acid Naphthionic ..	2s. 8d. ,, ,, ,,
Acid Neville and Minther	6s. ,, ,, ,,
Acid Sulphanilic ..	1s. 6d. ,, ,, ,,
Benzidine Base ..	6s. 6d. ,, ,, ,,
Dinitrobenzene ..	1s. 3d. ,,
Diphenylamine ..	4s. 1d. ,,
α-Naphthol ..	2s. 9d. ,,
β-Naphthol ..	1s. 2d. ,,
α-Naphthylamine ..	1s. 7d. ,,
β-Naphthylamine ..	4s. 6d. ,,
p-Nitraniline ..	3s. ,,
Nitronaphthalene ..	1s. ,,
R. Salt	2s. 5d. ,, 100% basis
Napthionate Soda	2s. 8½d. ,, ,, ,,
Aniline Oil and Salts	10d. per lb. naked sellers' works
Dinitrotoluene 48/50	8½d. ,, ,, ,, ,, ,,
,, 66/68	1s. 2½d. ,, ,, ,, ,,
Nitrobenzene ..	8d. ,, ,, ,, ,, ,,

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The raw material for **Citric** and **Tartaric Acid** derivatives is again dearer this week owing to the continued appreciation of the Italian exchange and prices of these products therefore keep firm. The market for **Citric Acid** is still quiet at 1s. 6d.—1s. 8d., and **Tartaric Acid** 1s. 1½d. to 1s. 2½d., both delivered and less 5 per cent.

Cream of Tartar is in good demand and prices are firm at 100s. per cwt., less 2½ per cent. delivered.

Acetyl Salicylic Acid is in very strong demand at 3s. per lb. The same applies to **Salicylic Acid** at 1s. 4d. to 1s. 6d.

There is a fair demand for **Bismuth Salts** at unchanged prices, but the market for **Bromides** is rather flat.

Iron Perchloride is unsteady at 18s. to 20s. per cwt. in consequence of German offers at low prices.

Magnesium Oxide, heavy, is steady at 2s. to 2s. 3d. per lb.

Mercurials are unchanged in price, although **Mercury** itself is rather dearer.

Potassium Iodide. The demand for this product is extraordinarily heavy at 15s. 8d. to 16s. 5d., and no offers are being made from Japan. There is a possibility of an increase in the price of **Iodine.**

Among photographic chemicals **Amidol** is offered at 9s. per lb., carriage paid, while **Sodium Hyposulphite Pea Crystals** are quoted at £15 to £17 per ton, according to quantity, carriage paid to buyers' station.

Paraldehyde is offered at 1s. 6d. per lb.

With regard to other products in this section the position is substantially the same as reported last week.

PERFUMERY CHEMICALS

Several of the products in this class show a fall in value this week, notably **Linalol** and **Linalyl Acetate, Phenyl Ethyl Alcohol, Terpeneol** and **Vanillin.** Exceptionally, however, **Methyl Benzoate** shows a sharp rise in price.

Prices of the chief chemicals in this section are as follows :—

Amyl Acetate	2s. 3d. per lb.
Amyl Butyrate	8s. ,, ,,
Amyl Salicylate	3s. 3d. ,, ,,
Anethol - Melting point 21/22° C.	4s. 6d. ,, ,,
Benzyl Acetate from Chlorine free Benzyl-Alcohol	3s. 3d. ,, ,,
Benzyl Alcohol free from Chlorine	3s. 3d. ,, ,,
Benzaldehyde free from Chlorine	3s. 3d. ,, ,,
Benzyl Benzoate 19.5° C. ..	3s. 3d. ,, ,,
Cinnamic Aldehyde 98/100 Natural	15s. ,, ,,
Citronellol	22s. 6d. ,, ,,
Citrol 100%	10s. 6d. ,, ,,
Ethyl Phthalate	4s. 6d. ,, ,,
Eugenol 100%	10s. 6d. ,, ,,
Geraniol (from Palmarosa)	32s. 6d. ,, ,,
Geraniol	5s. 6d. to 12s. 6d. per lb.
Linalol ex Bois de Rose ..	18s. 6d. per lb.
Linalyl Acetate ex Bois de Rose Linalol	19s. 6d. ,, ,,
Methyl Benzoate	10s. 6d. ,, ,,
Phenyl Ethyl Acetate ..	10s. ,, ,,
Phenyl Ethyl Alcohol ..	17s. 6d. ,, ,,
Rhodinol	52s. 6d. ,, ,,
Terpineol	2s. 10½d. ,,
Vanillin, 100%	25s. ,, ,,

ESSENTIAL OILS

Almond Oil, foreign, 17s. per lb., English 20s.

Anise Oil has recovered to 2s. 2d. per lb. after a short set-back.

Bergamot Oil, 14s. to 16s., according to quality.

Bourbon Geranium Oil, 24s. 9d. to 26s., spot, supplies are very scarce and forward quotations very firm.

Camphor Oil (White), 85s. per cwt., very quiet.

Cananga Oil (Java), 8s. 9d. to 10s. per lb.

Cinnamon Oil, leaf, 4d. to 4½d. per oz., rather more enquiry.

Cassia Oil, 8s. 7½d. to 9s., scarce on spot. Forward quotations are about 2s. cheaper.

Citronella Oil (Java), firm at 3s. 3d. to 3s. 6d.

Citronella Oil (Ceylon), 2s. 5d. to 2s. 6d. per lb.

Clove Oil, 8s. to 9s. per lb. Quotations for Jan-Feb. delivery are being made from 6s. to 6s. 3d.

Eucalyptus Oil, 1s. 4d. to 1s. 10d., according to quality.

Lavender Oil, 11s. to 14s. 6d., according to quality

Lemon Oil, 2s. 10d., spot. The product fluctuates considerably, but on the whole the tendency is upward.

Lemon Grass Oil, 2¾d. per oz., is very quiet.

Orange Oil (Sweet), 9s. to 9s. 6d., spot. Quotations for shipment, 8s. to 8s. 6d. per lb.

Otto of Rose Oil (Anatolian), 24s.

Palma Rosa Oil, 22s. to 24s., spot, but difficult to find. Quotations for shipment, 16s. c.i.f.

Peppermint Oil (English), 70s. to 80s., but demand small.

Peppermint Oil (Wayne County), 13s. to 13s. 6d., firm and slightly dearer.

Peppermint Oil (Japanese), 8s. to 8s. 6d., slightly cheaper.

Petitgrain Oil (Paraguay), 6s. 9d. to 7s. per lb., flat and being offered freely.

TRADE NOTES

The Quebracho Industry in S. America

The quebracho forests of Argentina and Paraguay are in danger of extinction unless provision is made for systematic replanting and general conservation. In 1922 not more than 71·3 million metric tons of quebracho was standing in Argentina and 3·5 mill. t. in Paraguay. As the potential production of quebracho extract in the two Republics is at least 240,000 t. per annum, and 1 ton of extract is obtained from 4·75 t. of logs, the annual cut of wood for the tanning industry alone must amount to 1·4 mill. tons. The danger of denudation becomes still more evident when it is realised that large quantities of wood are consumed for constructional purposes, and that there is a large annual output of logs (108,945 t. in 1917; 56,582 t. in 1920). Further, as the railways extend through the forestal regions exploitation of quebracho will be facilitated. From these and other causes it is estimated that the life of the existing forests will be reduced to 20 or 25 years. Re-afforestation should not prove difficult, because the natural stock can be replaced in 25 to 50 years, if suitable methods are used.

The dissolution is announced of the Quebracho Trust, which comprised about 70 per cent. of the producers of extract, the chief being the Forestal Land, Timber and Railways Co. The trust was organised for the sale of extract, but was not entirely successful, owing to competition from producers who were not members. As a result of the dissolution, prices have fallen from £23 to £21 per metric ton, and it is expected that the weaker producers will gradually be eliminated.—(*U.S. Com. Rep., Nov.* 6, 1922.)

The Alcohol Industry

Grain was originally used as the raw material of the German alcohol industry, but heavy taxation forced the distilleries to move into the country districts and substitute potatoes for grain as raw material. Before the war about 80 per cent. of the alcohol distilled in Germany was made from potatoes, of which 2·5 million tons was utilised by 6000 distilleries with an annual output of 66 million gallons. Supplies of raw material have always been short, especially in 1916–17, when the production fell by over 50 per cent., and the subsequent loss of the Posen district to Poland has reduced the productive capacity by 25 per cent. At present foreign grain has to be imported, as prices of potatoes are adjusted to conserve the crop for use as food. Since 1919 the industry has been a monopoly of the State, which supervises production and distribution and fixes the sale price. In recent years production of alcohol has been as follows:—

	Gallons
1913–14	84,568,000
1917–18	51,876,000
1918–19	29,062,000
1919–20	13,420,000
1920–21	40,304,000
1921–22	*24,200,000

* Estimated.

The increased output since 1919–20 is due chiefly to the use of imported grain. On August 15, 1922, the price of grain alcohol and of potato spirit was 5000 and 1000 marks per hectolitre, respectively, corresponding to 1s. 6d. and 3½d. per gallon, at the rate of exchange then current. Up to October, 1921, the price was the same for each kind.—(*U.S. Com. Rep., Oct.* 30, 1922.)

The German Chemical Society and Trade with Japan

The following items of interest are taken from the report of the meeting of the German Chemical Society on November 13:—

A new ship for the Hugo Stinnes Shipping and Overseas Trading Company was christened at Wilhelmshaven on October 14 by Mrs. Eugenie Piloty, a daughter of the late Prof. A. von Baeyer, the name "Adolph von Baeyer" being given to the vessel. Professor R. Willstätter delivered an address expressing the satisfaction of the German Chemical Society that this vessel of 8000 tons, intended for passenger and goods traffic between Germany and Japan, should carry the name of one of the founders of the Society.

At the unveiling of the Baeyer memorial at Munich on October 20, Dr. O. Hahn announced that the Japanese industrial leader, Mr. Hojimi Hoshi, who two years ago gave 2 million marks for the promotion of chemical science in Germany, had now signified his intention of making further gifts. Mr. Hoshi proposes to make a contribution of about 8 million paper marks (about 2000 yen) per month for three years for the support of chemical research, and to give a further sum of 40 million marks for general cultural purposes in order to express his sympathy for Germany.

The Cement Market in Jamaica

Imports of cement into Jamaica during 1921 totalled 3905 long tons, of which the United Kingdom supplied 53, the United States 28, and Canada 17 per cent. Most of the imported cement conformed to the British standard test and was therefore admitted at a reduced rate of duty; cement which does not pass the test is dutiable at a much higher rate. Wooden barrels holding 400 lb. are preferred as containers. The demand for cement is likely to increase in the near future, but, although the British product now dominates the market, Canadian competition is very keen.—(*Comm. Int. J., Can., Sept.* 23, 1922.)

The Match Industry in Latvia

The A.-G. W. A. Lapschin has purchased the match factories of L. A. Hirschmann in Goldingen, Libau, Riga, and Frauenburg, and as the administration has been transferred almost entirely from Russia to Riga, the company is entirely Latvian. New plant has been installed in the Libau factory, and the Goldingen factory is to be extended, so that the two factories will eventually produce from 100,000 to 120,000 cases of matches per annum, a quantity on which the excise duties alone will amount to 25 million roubles (Latvian rouble = about 0·17d.). The factory in Frauenburg produces only matchwood for export.—(*Chem. Ind., Sept.* 25, 1922.)

Transport of Samples by Passenger Train

We are informed by the Association of British Chemical Manufacturers that as the result of its negotiations with the Railway Companies the following new Regulation will come into force on and from January 1, 1923:—"Samples of inflammable liquids and substances made therefrom be accepted for conveyance by passenger train, provided each sample is contained in a sealed glass bottle, not exceeding 8 oz. in capacity, packed in a wooden box containing sufficient sawdust to absorb the whole of the liquid in the event of leakage; the traffic will be conveyed at owner's risk only and will be charged full parcels rates, including collection and delivery within the usual limits at places where arrangements for these services are in operation. The appropriate form of owner's risk consignment note must be signed."

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, JANUARY 12, 1923 No. 2

EDITORIAL

THE letter which we print in this week's issue from Viscount Leverhulme deals with so important an aspect of chemistry and industry that we feel it should receive more publicity than was possible in our first number, which was prepared and published in what was to many of our readers, a holiday period. Viscount Leverhulme hopes that we shall include the human element in industry, as well as the chemical formula. He has for many years made a special study of this problem and his advice is therefore of value. How can we do anything to help in arriving at that proper consideration of the industrial situation which will utlimately produce industrial peace ? Only by publishing articles on both sides of this question and so providing a place in which the employers and the employees may put forward their points of view, consider the facts, perhaps new to them, submitted by those on the other side of the table, and devise the best means of bringing harmony out of the conflicting interests. If we can be useful in this respect, we shall achieve a success even greater than our President and Lord Leverhulme expect, and we look forward to a discussion on this topic in our columns by them, and by others who similarly occupy positions of importance in the industrial world.

* * *

It is worthy of remark that chemistry, now becoming so exact a science, a branch of knowledge which affects us throughout every phase of our life and plays an important part in every branch of industry, a subject referred to in a host of Acts of Parliament and Orders in Council, should have so few definitions. For some purposes exact definitions need not be formally stated : large contracts are made in "pig-lead—our usual brand," "caustic," and "B.O.V.," in circumstances which both buyer and seller clearly understand. It is when chemistry and chemical operations become the subject of legislation and litigation that some definite meanings become essential to the harmonious progress of the science and the community. Hobbes says in his Leviathan, "The light of human minds is perspicuous words, but by exact definitions first snuffed, and purged from ambiguity." The late Mr. W. G. Pogson Smith wrote : "A definition must be held to be satisfactory if it be clear. The master claims a free and absolute right of arbitrary definition. Agreement on definition is the *sine qua non* of intelligible reasoning." What trouble there would be if the Federal Council were to attempt definitions of "sovereignty," "command," and "sanction" ! The master minds in chemistry have the right to lay down the definitions of their science, and we hope the article from Sir William Pope will lead to universal agreement on this fundamental one which forms the subject of his writing. We know that hasty legislation sometimes encourages the use of vague phrases, and that the wiliness of the politician sometimes deliberately finds these are the line of least resistance. Many a man in the old days was returned to Parliament as a Tariff Reformer, who would have been rejected if the exact meaning of Tariff Reform had been explained, the exact duties to be levied on each commodity set out in a schedule and so on. A vague phrase like "heavy chemicals" may be rushed through a tired House of Commons when a detailed list would provoke opposition which cannot be overcome.

The subject is of such importance to the whole chemical community that we are inviting other contributions on this topic and we hope at a later date to be able to deal with the matter in a manner worthy of the attention it requires.

* * *

One of the principal functions of *Chemistry and Industry* is to provide a record, week by week, of the meetings of the many and far-flung Sections of the Society. To do this, we perforce must depend on the zeal of the local Honorary Secretaries, whose services—recently applauded in a Presidential Address—are given so freely, despite the pressure of more urgent duties. But a weekly *Journal* has an insatiable maw, and we would urge, with Herrick, that "old time is still a-flying," and that the prompt dispatch of accounts of Sectional Meetings is essential if our "News from the Sections" is to be of real service and interest. "News" which reaches us long after a meeting has already lost some of its value; other accounts may have been published elsewhere, and the member who, prevented from attending a meeting by seasonal ills or more frivolous engagements, is desirous of acquainting himself with the proceedings, and fails to find an account in these columns within a reasonable time, is not without just cause of complaint. No time is lost between our receipt of any News from the Sections and its dispatch to the printers, and we therefore ask all Honorary Secretaries of Sections and Authors of papers to collaborate with us in ensuring that reports of Sectional Meetings are published with the minimum delay.

* * *

In our last issue we published an article in which Prof. H. E. Armstrong strongly condemned a recent legislative effort in connexion with the supply of pure milk. An interesting commentary on this criticism is supplied by a note in the *Manchester Guardian*, which states that although the Milk Act has been in force a week, hardly any notice has been taken of it in London. On Thursday, a request for "a pint of first-class milk" met with the response "what is first-class milk?" but on Saturday the same request elicited the reply that "first-class milk costs 7d. per pint . . . !" We are reminded of Sir William Pope's letter to the *Times*, quoted in our last issue, in which he suggests that, owing to faulty draughting in the Safeguarding of Industries Act, the confusion in interpreting terms such as "organic" and "fine" chemicals has not been without benefit to the legal profession. It is almost impossible to over-estimate the importance of the milk question. In the old days, when children were reared in the country and in small towns, they usually obtained a sufficient amount of good milk and of good and wholesome food of other descriptions. Now, owing to the huge population which this country has to support and to the habit, a product of our modern civilisation, of crowding together in large towns and cities, the young children who are to be our future citizens are becoming more and more dependent on foods artificially manipulated and preserved. The foods so treated have not the same qualities as the fresh ones. Preserved meats, preserved vegetables, highly cleaned and whitened flour and such things have not the same value as foodstuffs as the articles which were obtained fifty years ago. So long as fresh milk of a good quality was available this compensated to a great extent for the deficiencies of other foods for children. But now we are threatened with milk which has been sophisticated or pasteurised, and we have no reason to think that such milk will have the properties of fresh milk. The future of all young children in towns—and how large a proportion these form—is in jeopardy. The question requires urgent attention.

LETTERS

From

The Rt. Honble. Viscount Leverhulme

Chairman of Messrs. Lever Brothers, Ltd.

I am very glad to hear that the Society of Chemical Industry have decided that, commencing with next January, they will issue their Journal weekly under the title of "Chemistry and Industry," instead of fortnightly as at present.

One of the greatest Generals the world ever produced said that an army moved on its stomach, but I am certain that however an army might move, the art of warfare and the art of peace both equally move on the science of chemistry and industry. This science has made giant strides during the last century, and if only our knowledge of human nature and our handling of human nature in our industries had kept pace with the science of chemistry, I am confident that all the present so-called industrial unrest would never have existed.

Therefore the linking together of Chemistry and Industry in the title of your paper I hope includes the human element in industry as well as the chemical formula. There is just as certainly a formula for dealing with human nature as there is a formula for dealing with organic and inorganic chemistry, and the principle underlying the formula for human nature is "sympathy" and "brotherhood."

From

J. Arthur Reavell, Esq.

Chairman of the Chemical Engineering Group

The publication of the Society's Journal under its new name and as a weekly issue, instead of fortnightly, will no doubt be received with great satisfaction by the large majority of our members.

For a long while there has been severe criticism of the journal from many directions, and the most frequent criticism was that the news published in it had already appeared in the ordinary technical press.

If all the members will support the editor and his staff, and those who can write suitable articles and supply suitable technical matter to the new journal will do so, then the Society will have a really live publication that will appeal to every class of member.

The Journal of the French Society (*La Société de Chimie Industrielle*), started only a few years ago, has rapidly proved itself to be a most valuable technical journal, always providing its readers with thoroughly live technical matter. What has been done by our French colleagues can surely be done here, as we are certainly not lacking in talent, nor is the chemical industry in this country behind any other in the world.

There is no doubt that the Chemical Engineering Group will do their share in providing a considerable amount of up-to-date matter in the shape of papers read at their many meetings, and these papers should have the widest publicity for the benefit of the industry. Where can they get better publicity and a better reception than in the official publication of the Society ?

As Chairman of the Chemical Engineering Group, I will certainly give the new effort the heartiest possible support and I wish it every success.

From

Brigadier-General Sir William Alexander, K.B.E.

Chairman of British Dyestuffs Corporation, Ltd.

It is with great interest that I have heard of the proposal of the Society of Chemical Industry to publish weekly instead of fortnightly the Review portion of its Journal. "Bis dat qui cito dat" is as true of news as of subscriptions or presents, and it will be of real advantage to the members of the Society as also to subscribers in general to receive an earlier intimation of trade intelligence and of business operations. In making this change, the Society is treading the established path of development in the world of journalism. The tempo has been accelerated, and coexistent with the monthly and weekly reviews giving their considered surveys we have the daily papers keenly competing with each other for priority of news and the evening papers, with their many editions, recounting events, important and trivial, as they are taking place and occasionally showing the prescience of anticipation.

It is of the highest importance to the Chemical Industries, and thus to the community at large, that an expert finger should be kept constantly on the pulse of the news in its bearing, not only on commerce but on those advances in science which, in ever increasing measure and with greater promptness than before, are being exploited for the benefit of industry.

There is yet a further advantage in a quickened service. The pace at which information is scanned and absorbed and acted on bears some ratio to the intervals between its appearances.

The monthly reviews languish in state on our tables, while the columns of the evening paper are harvested immediately. The attention paid to news and reports will, I think, be increased by the weekly appearance of the Review, and there will also, no doubt, be some beneficial effect on the news-getting services themselves.

I congratulate the Society on this progressive move and wish all possible success to the new undertaking.

LEGISLATIVE AND DEPARTMENTAL INTERFERENCE WITH INDUSTRY AND THE COMMON WEAL

(*Continued*)

By PROF. H. E. ARMSTRONG, F.R.S.

The street-hawker of fruit to-day spells salvation to the masses and should be highly honoured of men; the town office-worker, who is no longer fed from the grill but on long-stewed food, would probably go under were it not for his services. If salads, fruit and raw milk were substituted for cigarettes, the proportion of C3's would most certainly be diminished.

I may say in conclusion, that I have had the opportunity, during the war, of seeing the detrimental effect, upon the development of a large number of boys, of the lowered diet to which they were necessarily condemned; the effect in medical opinion is continued and obvious to-day. Boys of the age of those I refer to when the experiment began, who have been under improved post-war conditions, are not showing similar effects—so that these cannot well be set down to the conditions of boarding-school life, other than feeding.

I have already spoken my mind on this subject in *Nature*. Thus far I have received no public support from my "biochemical" friends, neither have they sought to controvert my view. The prefix they have chosen to adopt appears to me to be meaningless—they are a lifeless crowd. The time is at hand when all chemists must realise that their first duty is to themselves—to understand themselves. The Organic Chemistry of to-day has nothing to do with real life; we must restore to the term organic its proper meaning and organic chemistry must be the primary study of every would-be chemist. To-day there are few whose opinion is of value on any vital problem—we prefer to consider problems of purely commercial value, instead of those of health and life. Hence my lone tears—for as yet I have found no one to weep openly with me. I trust I have moved some of you.

To deal with the subject exhaustively would occupy hours. My desire to-day is to stir you into activity on your own behalf—on behalf of your own and your friends' children and of the public at large. This will be upon your conscience, if you do not act! It is essential that you should aid in pressing upon the public the unique value of milk for children and in every way seek to promote the production of an ample supply of safe and high quality.

Smoke Abatement

I am led to touch upon this subject, as it was the chief topic of my address to this section in 1917; also and particularly, because I would call attention to the misdirected zeal displayed by the Ministry of Health and at least one other Government Department. That smoke is a curse to us in our cities, we are all aware, and need no proof of its evil effects. We regret fog the more as, in the winter season it is the product of fine weather; hence, this year in London, fogs have been exceptionally prevalent—there has been neither wind to blow them away nor rain to wash them down; but even in London they have been curiously patchy and sharply defined, an indication of special local conditions. What is science doing to rid us of the nuisance? Nothing; only measuring it! Continually it doth cry, regretting the magnitude thereof—but mere crocodile tears such as are shed will never wash the dirt from our sky. In one of our recent worst fogs, at South Kensington, the pundits were seen solemnly enumerating the soot particles, while close at hand the chimney of a works engaged in combating the nightmare was belching forth dense clouds of black smoke, which made the fog appear luminous—no doubt the "average" arrived at was duly recorded against the fog demon. Formerly we had the reputation of being a practical race; to-day we but live on this reputation, gained for us by our uneducated, unscientific forefathers. Seemingly education and science have deprived us of all *nous*!

Smoke has ranked with Divorce and the Criminal Courts, in public interest, during years past; every woman in the country is alive to the nuisance—and does her best to perpetuate it; many men have sufficient intelligence to bemoan it, as it interrupts their journey to "work." A Smoke Abatement Bill was introduced into the Upper House by Lord Newton, in the 1914 session. It was withdrawn, upon an assurance of the President of the Local Government Board that he would appoint a *strong* Departmental Committee to deal with the subject. A Committee was appointed but action was suspended during the war; it was reconstituted by the Ministry of Health in January, 1920, with Lord Newton as chairman. The Report has been the subject of recent discussion and a Bill embodying some of its recommendations was submitted to the House of Lords at the close of last session; this Bill did little more than increase the fines upon offenders; no notice was taken in it of the sparse constructive proposals in the Report of the Committee.

The Committee was charged to consider "the present state of the law with regard to the pollution of the air by smoke and other noxious vapours and its administration and to advise what steps are desirable and practicable with a view to diminishing the evils still arising from such pollution."

It was of the usual character, technically unqualified in the main; certainly not "strong"; it had but one chemist and he had been engaged only in measuring fog and its effects—things which no one wants measured, as they appear in every washing or decorator's bill—not constructively in promoting smoke prevention. As I remarked recently at the Royal Society of Arts, when appointing the Committee, the Ministry of Health should have applied to this Society to nominate three fit and proper persons to serve on the Committee, to deal constructively with the problems of smoke.

The Committee heard about 130 witnesses on 20 days. Nearly all the evidence was directed to proof of nuisance and in some cases to the difficulty, if not impossibility, of avoiding it. Very little constructive evidence was taken and this related to the use of gas or central-heating appliances. Smokeless, easily combustible, solid fuel was considered only on two occasions—the 13th and 20th days. No scientific evidence was given on the subject. The printed evidence occupies 390 folio pages and is an informing, though for the most part futile, document. Why it has not been issued, it would be interesting to know.

We are told that £1,517 5s. 10½d. is the estimated gross cost of printing and publishing the sketchy final Report and the interim Report, including the expenses of the Committee.

There can be no question that Lord Newton and the other members of the Committee did their utmost but the task was beyond such a body; it had not upon it a sufficient number of persons versed in the subject and particularly no one of constructive outlook. A great deal of money has been spent to no purpose—in proving what is generally known and deplored; the Committee had no proper scientific outlook, it therefore made no use of scientific method.

If the proposed Act had been passed, it would but have raised the fines to be laid upon the poor smoke producer, who sometimes suffers from his own ignorance but more often from that of his agents, whose carelessness it is almost impossible to overcome.

Our false system of education, affecting as it does all grades of society from that of the House of Peers downwards, is the main cause of the smoke nuisance. Had the responsible members of the Ministry of Health been properly educated, they would have constituted the Committee of men who would have dealt with the problem constructively from the beginning.

All the Committee has done on the constructive side is to advocate the greater use of gas and central-heating—two methods, we know, which have the disadvantage of being definitely less favourable to health than our present system of open firing. Dust fuel, which in the future is likely largely to displace gas firing and probably will be the solution of most of the difficulties of large scale heating, was not considered.

Smokeless Solid Fuel

This came under the notice of the Committee and it is clear that the advantages and possibilities of an easily combustible fuel produced by carbonising coal at low temperatures were realised. Apart from Mr. MacLauren's evidence on the 13th day, the subject was dealt with, as I happen to know, entirely by accident, only on the last (20th) day. A great opportunity was therefore missed of displaying to the public the case for such fuel free from partisan advocacy. The baldest possible reference is made to the subject in the report.

To quote one paragraph : " For some years various experts have been endeavouring to discover some practicable means of carrying out low-temperature carbonisation under commercial conditions. In particular, the Fuel Research Board have conducted, during the past two years, at H.M. Fuel Research Station, experiments with a considerable variety of coals and have determined the yields and quality of gas, oil and coke produced under definite conditions."

It is an astounding fact that the endeavours referred to have been made by persons having no connexion with coal interests—of the inventor type. Government has never moved in the matter. No colliery proprietor, none of the great users of coal at Sheffield or elsewhere, none of the Gas Companies, had touched the problem of low temperature carbonisation up to a few months ago. Fortunately, though methodless, we are a sporting race : as usual, private persons, gifted with some imagination, some foresight, some spirit of adventure have stepped into the breach and though technically utterly incompetent for the task and always unsystematic in their ways, at the expense of their own and other people's fortunes, have struggled on doggedly and won through—I say, won through advisedly. Given efficient co-operation of chemist and engineer and systematic study, the problem would have been solved years ago.

At last even the Gas World is catching the low temperature disease, though the technical press is still seeking to vaccinate against its spread. Success was being achieved, until recently without help from Science.

As to H.M. Fuel Research Board, referred to in Lord Newton's Report as though it represented something real, the information that has emanated from this august body is worthless for all practical purposes. Its programme seems to be merely to bake sponge cakes from every sort of coal, instead of from sugar and flour ; to find out what the cake weighs and what is lost in baking it. No one who has to deal with coal in practice will have any use for this information. The weight of the cake produced from a given coal at a given temperature is fairly constant and may be easily determined in any chemical laboratory, with ordinary appliances, at no great cost of money or time. The yield of gas and oil at a given temperature, under one set of conditions, is of little value ; by varying the conditions without varying the temperature great variations in the relative proportions of gas and oil are easily induced : the volume may be more than doubled.

The business of a National Fuel Research Board should be not to undertake work not even of academic value but to aim at practical results and to help, by honest co-operation with all the agencies in sight, to secure the result which, on all hands, is accounted to be that of greatest industrial importance in the life of our nation—the production of a suitable, smokeless fuel, at an economic price. If we can render our cities clean and clear and at the same time economise coal, we shall enter into a new heaven upon earth. There is no present prospect that H.M. Fuel Research Board will contribute to this end—it works in secret and takes no cognizance of outside knowledge ; it seems to have no practical outlook ; and what is its cost ? No accounts are published. Sir Charles Parsons told us at the Bournemouth British Association meeting in 1919, that the primary cost of the Station at Greenwich would be £250,000. There must have been a large maintenance expenditure in the interval. It is clear that the organisation needs overhauling and reconstruction—if indeed it be in any way worth while to maintain it in existence.

The problems of fuel are the problems of first importance for us to consider, as our nation, for the most part, is fed upon coal and we cannot sufficiently use our coal to feed the large number we have encouraged into existence through its extravagant use. Chemists in the gas industry have perforce greatly neglected the subject hitherto ; their place has been usurped by the engineer and by one of very narrow outlook. Ere long, however, the gas industry will be ranked one of the first of chemical industries and the fascination of the problems it presents clearly recognised. The gas-works chemist must soon be fully in evidence ; he must be a whole one. Fortunately your treasurer is leading the way ; you will shortly have to recognise him as an organic chemist *pur sang*, a reverent student of the past, bent on making honest use of the capital the past has given us.

Gaseous Fuel—The Therm

As not even the patronage of H.M. Fuel Research Board has been able to secure public belief in the Therm, a Committee of five has been appointed by the Board of Trade, I assume, to inquire into the complaints that have been raised. Of course, as usual, the Committee consists of men who have no knowledge of the subject they are to consider—consequently they will have no feeling for it and will necessarily accept the view most alluringly put before them. In the end the public will not be enlightened.

Again I say, the Federal Council or this Society should be asked to nominate fit and proper persons to serve on the Committee. If we are to live with gas in the future, at all events until we put our heads into some oven filled with gas, it were well that we were taught to understand and respect the fluid; also that some agreement were laid down as to its composition—a matter of some concern to us. This great opportunity is offered by the inquiry and it should be conducted to such end.

THE FEDERAL COUNCIL

You are to publish a weekly *Journal*, which is to be the proclaimed organ of the Federal Council for Pure and Applied Chemistry. The said Council, thus far, has had a shadowy form; that the conception behind it, the great ideal it embodies, is real, is shown by the very fact that its achieved existence and influence is now to be so publicly admitted and proclaimed. The future of chemistry in this country depends upon the extent to which chemists generally are mastered by that ideal, upon the way in which they qualify to be its recognised exponents.

The ideal is that of solidarity—the subordination of mere individual interests to those of the body politic, more particularly to those of the Science we profess and proclaim to be fundamental to all human activity, indeed to the world at large: *as all life has its being in chemical change.*

This must be our constant message to the public and to those who would govern us to-day. We are no mere analysts, to be called in when some chief of police eats promiscuous chocolates or a man gives poison to a wife of whom he is tired; we are not mere dispensers of drugs: *we are the masters of the materials which make the universe;* all industries, including agriculture, can be made subject to our control; in fact, the only people who can have no use for us and who may well hate us are the clerics: we cannot picture a world made at the rate suggested in Genesis, nor in the manner described in the books which they so often misread to the public. Up to the war, in this country, chemists were in the wilderness; the opportunity given during the war was taken by not a few and our science came into repute. There is great danger that the shield thus won may not be held, unless the greatest care be taken to maintain a strong team. The system of training is seriously in fault. The production of bits of chemists in place of whole chemists is a proved failure. The Federal Council is itself proof of chemical tit-bit'ry; it will only be a really Federal body when it is a Council of Chemists, one and indivisible, all working together, though may be in different walks. I say this to mark my opinion, that the setting up recently of two new independent hives is not a healthy sign; it is proof that the altruistic co-operative spirit is not yet sufficiently alive among us. We are at the most critical period in the history of our nation. A misdirected, scientific zeal has brought us into possession of a population which we cannot carry. Science, properly used, alone can save us; but science has to force its way through and to the fore; it will receive no invitation from the democracy, whose spirit is congenitally unscientific and not to be educated; we have the whole literary and clerical clan against us and this is not to be handled with gloves.

A PALACE OF CHEMISTRY

If successfully conducted, your new venture will spread the Federal ideal; ultimately the ideal will be embodied in a Palace of Chemistry. One of the most prominent buildings in Brussels is the Palais des Académies; this name appears in big letters on the cornice. The Federal victory will only be won when British chemists similarly proclaim themselves in some one of the great throughfares of London and a focus is provided where all can meet and find a common home. The further aim should be, moreover, to make that Palace an acknowledged *Palace of Truth*, one in which judicial methods are alone practised and no false worship of icons of any kind is permitted.

THE USE OF LEAD IN PAINTS

I have painted the milk of to-day as a whited sepulchre. Let me now point out how the bureaucrat and sentimentalist ocmbined would deprive us of the most efficient of our White Paints. This time, it is the Home Office that would hamper us, and again we have to deal with a semi-scientific tyranny, emanating not from the bacteriologist but from the medical man, overcome by the humanitarian desire to protect a particular class, but unprepared to consider either the needs of industry or the requirements of the public.

Nearly ten years ago, in April, 1913, Mr. C. A. Klein and I brought the subject directly under the notice of your Society, and our communication, we believe, has not been without influence on subsequent official action. I may note here that your eminently respectable Publication Committee made many alterations in our paper, so depriving it of all point and significance; these we successfully resisted. I offer this remark, in no way of complaint but to make clear my view, that open and free expression of considered opinion is the need of our time and that your Society will prove of value in proportion as it provides a platform for such discussion. You must be a fighting body, if you are to progress: as Recording Angels, you may be ornamental, but of little use.

(*To be continued*)

MEDITATIONS OF A SODIUM ATOM

Collected by "Meniscus"

These racy "meditations," perhaps "rhapsodies," are really nearer the truth, form one of the essays sent in by members of the staff of the United Alkali Company, Ltd., in a competition to celebrate the Centenary of the foundation of the Alkali Industry in this country. The Company must be congratulated on a finished product so suitable for this interesting occasion and we hope other firms will follow this example.

* * *

EXULTANT! I am overwhelmed with joy. It is 1923 and I celebrate the Centenary of my crowning glory. One hundred years ago I arose from darkness to the dawn of a new day of usefulness and service, radiant with hope for the world of man. How often do I puzzle scientists and doctors, almost driving them to despair as they seek to elucidate my mysteries and fathom the secret precincts of my nature. They call me a Sodium Atom and what strange guesses have been made regarding me. From Democritus and Lucretius to Dalton a thousand theories have held their sway, and as each new one is propounded I just laugh at their efforts, and wonder "Shall I tell?" Ever ready to render service unto man, the infinite numbers of my family are scattered throughout the world in a variety of relationships. In the world's childhood, long ago, change was ever my lot, and as the mass of earth cooled down I was diffused through the whole, but my great affinity for Chlorine resulted in my being hidden in the depths of the earth, to be known to man as Sodium Chloride or Common Salt.

The years rolled by and we were left untouched or unheard of, with only an occasional effort to organise for man's service the millions of tons of salt. Indeed, apart from use as a food preservative, no other use seemed available.

To me such an existence spelled monotony; the relationship with Chlorine bored, and I longed for the time when man should liberate and utilise me for his service.

The dawn of a new day was breaking, Lavoisier, Guyton de Morveau and, greatest of all, Nicholas Leblanc, were tunnelling through the walls of night; freedom and liberty were in sight. Alas, the fires of Blood Red Revolution swept through France; Lavoisier perished, condemned to the guillotine. Nicholas Leblanc died, and the fruits of his labours were unexplored.

The young French Physician poured forth energy of mind and will in the determination to attain a prize of about £100. "It shall be done; no longer shall soda be exclusively obtained by burning wood and treating the ashes with lime." The fires played round the crucible, and Leblanc's great process was accomplished. The Product of Salt and Sulphuric Acid heated with coke and lime had yielded the precious Soda.

Cheated of his prize, and later, deprived of his works, Nicholas Leblanc was plunged into dire, distressing poverty, and with the burden of sorrows and age he sought refuge in a workhouse. In 1806 he perished by his own hand. So ended the life of one, whose name was to become immortal.

* * *

An anxious waiting company of men and women assembled on the sun-kissed plains of Holland, eagerly gathered round the arriving coach. That something was wrong appeared evident by the gloom which overshadowed their faces. For many weeks, day after day, the group had gathered to discuss the non-arrival of yarns and cloth from Scotland to be bleached. A strange tale seemed to fall from the lips of a man who had stepped from the coach. Speaking to the bewildered throng, he continued, "They are able to do in Scotland in twenty-four hours what has taken us months and months to perform. Someone named Tennant has opened a Works at Glasgow. He mixes Salt and Manganese together and treats them with Vitriol and an evil gas comes off, but this strange gas he passes through lime and extracts with water, and lo! when the yarns are just dipped in, out they come whiter than the fairest lily, whiter than the Arctic Snows."

In 1799 Charles Tennant had opened a small Works on the Clyde for the manufacture of Bleaching Powder, but I, Sodium, who had held Chlorine so long and had now yielded it up for man's service, was treated as a necessary evil and along with Manganese and sulphate was cast away as refuse, until later, when, as Weldon Mud, the ingenuity of man found utility for this apparent waste.

* * *

About 1822, in a quaint room in Dublin, a piece of Salt lay surrounded by retorts and flasks, upon a table. Meditatively James Muspratt fingered the small white mass. His keen eyes showed talent and perception. Determination, restlessness, passion, daring, were inscribed on his personality. "Only a piece of Salt, but in you lies untold wealth, in you lies the prosperity of Dear Old England—Leblanc—Liverpool—the Mersey with its vast facilities for foreign trade—."

The heavy Salt duty had been removed. Slowly the first great British Chemical Works arose in Vauxhall Road, Liverpool, and in 1823 James Muspratt commenced manufacturing on a commercial scale the soda and its by-products which were to prove the foundation of a thousand other industries and of Britain's Commercial Supremacy.

So rejoice with me. 1923! The Centenary year of my Crowning Glory.

In the process of the preparation of Soda, Salt is first treated with Vitriol and the Chlorine is liberated, but immediately combines with Hydrogen to form Hydrochloric Acid Gas, and Oh ! the havoc of that gas. Farmers cried out against its devastating work on their crops ; buildings began to fall before its corroding action ; high chimneys failed to carry away the torrents of the gas, and the Alkali Industry seemed in jeopardy, unless something could be done to counteract the deadly fumes.

In 1836 a remedy was proposed by William Gossage, namely, the erection of coke tower condensers through which trickling water would absorb the gas. But on approaching James Muspratt, Gossage received a rebuff and Muspratt, thinking only of the magnitude of his works, exclaimed " Sure ! all the waters of Ballyshannon itself would not suffice to condense the acid I produce."

However, the Gossage Towers did work and effectually condensed the acid. But further troubles were soon to be experienced, for the excess Hydrochloric Acid was running to waste into the Canal and the boatmen found the rivets dropping from their barges with the resultant sinking of them.

* * *

Chlorine was known and utilised for service, but linked up with Hydrogen, it formed a dangerous combination, and to separate the two was indeed a problem.

The Handmaids of Patience and Perseverance waited upon the labours of Henry Deacon, and success at length crowned his efforts and research. The troublesome gas was passed over heated Copper salts and what joy beamed upon his face when Chlorine was evolved. The Deacon Process was patented as the most economical method for the preparation of Chlorine, the vital element in Bleaching Powder.

The service of Chlorine can hardly be estimated, and its production runs to several thousand tons per annum. Man has overcome difficulties of handling, and now it is sent out in its elemental state compressed to a liquid, in iron cylinders. Should the supply of Chlorine cease, all paper makers would despair, sanitary inspectors would forsake their posts, doctors could no longer administer Chloroform to their patients, white clothes and linens would be luxuries for the rich ; many dyes also would sink from the memory of man should this valuable element fail.

* * *

Widnes had become the scene of operations for Muspratt and his co-workers, but whilst the flourishing Industry was springing up on the Merseyside, similar operations had commenced on the Tyne under the control of Christian Allhusen. A transformation had taken place in St. Helens. Instead of green fields, with orchards and thatched cottages, the tall chimneys of chemical works had made their appearance. Such men as Josiah C. Gamble, who was the first chemist to introduce into the United Kingdom the working of Vitriol Chambers, Henry Baxter, and Andreas Kurtz, have their names inscribed in the annals of the British Chemical Industry.

Kurtz, operating at the Sutton Alkali Works, had gained the reputation of having the best equipped and managed works in the country, and although he did not make St. Helens his place of residence, Andreas Kurtz remembered the place to which he owed prosperity, and erected Public Baths, and founded the St. Helens Cottage Hospital.

* * *

The tremendous capital involved and the mighty organisation required to direct the preparation of the Alkali Products was a gigantic problem, and towards the end of the nineteenth century, to prevent overlapping in working, and for economical efficiency, the various manufacturers were compelled to consider some practical method of co-operation.

Already over thirty different firms were working processes throughout the Kingdom, and at length the triumph came. United under a central board, united in aim and purpose, joining hand in hand in fellowship, the United Alkali Co., Ltd., was founded and registered as a Company on November 1st, 1890, to render efficient the manipulation of so vast an industry, and to serve the highest interests of the Empire.

All that was serviceable in the old firms was retained, all that hindered was scrapped, but progress did not end there. New discoveries were still to be made, modern machinery was to replace the old, and new processes were to be installed.

* * *

The four cardinal points of the Alkali Industry's greatness are Salt, Limestone, Coal and Pyrites, and one of the earliest efforts of the new company was the purchase of interests from the Salt beds at Fleetwood to the Pyrites mines of Huelva in Spain, thus assuring an adequate supply of these four essentials.

Product after product has been added to the list of manufactured Chemicals, and after these years of travail, forth I go as an integral part of every industry.

The Tanner for his leather uses Sodium Sulphide, Sodium Hyposulphite, and Sodium Sulphite ; the Glass Maker uses Sodium Carbonate and Sodium Sulphate ; the Paper Maker, Bleacher, Dyer, Soap Maker, Confectioner, Photographer, Scullery Maid, and Monarch use the products of which I form part.

* * *

Electricity has played her part in the production of the Alkali Products. I shall never forget that adventure. Into a large cell with Electrodes the brine was poured ; the current passed with a strange dividing sensation, and

I was drawn to the negative pole while Chlorine passed away as gas at the positive. Free, I sought union with Hydroxyl, was heated in great pans until the water had evaporated, then passed through intricate pieces of mechanism, and issued forth as Petal Caustic Soda. Now, prouder than any other member of my race, I reside within a bottle bearing on its face—A RED HEART.

* * *

O fair Ship "The United Alkali Co., Ltd.," thou hast sailed over many seas and thy strong bows have ploughed through calm and troubled waters. A backward glance reveals rough, rude promontories safely rounded, or hidden rocks safely passed. Thou hast weathered the winds of adversity, of coal and railway strike, of transport difficulties and engineering problems, and to-day thou art still as strong. There are yet unchartered seas to explore, there are yet discoveries reserved for thy seeking, the voyage ahead is full of Hope, and promises to be yet more glorious than the past.

Sail on; sail on fair ship, and the pages of history will record the necessities, the joys, the comforts and pleasures of life that have come to the human race through "THE UNITED ALKALI CO., LTD."

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

The Chemical Industry Club

I ASKED last week why there are so many Chemical Societies and Associations and hoped that the Federal Council would supply the "missing adhesive." Now it happens that very occasionally I pay a visit to the Club and my impression is that a good deal of the co-ordination of chemical effort is going on in a very unobtrusive manner in the Club premises. In their relation to chemical societies everyone is, for the time being, bound to identify himself with the interests of some particular body. Professor X is, this year, or hopes to be next year, the President of the Chemical Society; Professor Y is, this year, the President of the Society of Public Analysts, and next year he is invited to be the Hon. Treasurer of the Biochemical Society, and, at the moment, Mr. Z is the President of the Association of British Chemical Manufacturers. Such time as these public-spirited gentlemen have to spare for the organisation of our science and industry is more or less concentrated on the Society they are specially keen upon at the moment. But in the Club they are dissociated or ionized or whatever is the proper term. Their co-valency disappears, as Professor Lowry has explained, they wander about in the state of ions and are ready to help along any movement which is for the public good. The individuals, however, remain the same; the club members are, in other places, Fellows of the Chemical Society or Members of the Society of Chemical Industry, or the Mineralogical Society or they represent the companies whose interests the A.B.C.M. looks after. It is in the Club that they make their corporate influence prevail and their weight felt.

America and Ourselves

I have just had some very interesting news from America and hasten to record it for the benefit of future historians of our Society. It appears that our American friends have been considering the question of the more frequent publication of their chemical journal, and it is most interesting to note how closely their ideas approximated to our own. A news edition of the Journal of Industrial and Engineering Chemistry is to appear on the 10th and 20th of each month. The new publication is to have the same sized page as the regular monthly issue of the Journal and is to be separately paginated. Hearty congratulations to the American Chemical Society!

The Old and the New

The attempt of the London Section to brighten their monthly meetings may be regarded as revolutionary by some of us, but I am more inclined to regard it with equanimity since receiving a notice of a meeting to be held by the Shawinigan Section in "The Electro Products Camp on Transmission Avenue." A sufficiently picturesque place to draw a crowd, I imagine; but should this fail to draw a good attendance, other inducements are offered. Occasionally the words, "Smoking permitted," are added to such notices, not so in the case of Shawinigan. "The meeting," so the notice reads, "will consist of a real old-fashioned Province of Quebec Smoker," and "people from Ontario and the United States will be admitted if they promise to behave."

Montreal *v.* Shawinigan

The London Section is really out of the running, but I am not sure whether Montreal will be left at the post. The Montreal Section does not meet at a camp, but at the Queen's Hotel, nor are such futilities as "refreshments will be served" countenanced for one moment. The member is bidden to "bring two dollars for the hotel and take an active part in the *best one* yet." They do not "dine" in Montreal, but the members "eat dinner together." Punctuality is insisted upon: "The first olive goes down at 6.15 p.m. At 6.20 the olives will be —all gone!" It is very nice indeed to see how our friends across the seas secure their audiences, and if the London Section can do the same they will have a very successful session.

FORTHCOMING EVENTS

Jan. 11. Optical Society, Imperial College, S. Kensington, at 7.30 p.m. "Stellar Photography," by C. Davidson. "Ultra-violet Light in Microscopy," by T. E. Barnard. "Pitch," by F. W. Preston.

Jan. 13. Society of Chemical Industry, *South Wales Section*, Visit to National Oil Refineries, Skewen, at 10.45 a.m.

Jan. 16. Royal Photographic Society, 35, Russell Square, W.C., at 7 p.m. "Manufacture of Paper for Photographic Purposes," by H. W. Greenwood.

Jan. 16. The Chemical Engineering Group. Hull Photographic Society, Grey Street, Park Street, Hull, at 7.30 p.m. "The Manufacture of Wood Extract," by Mr. J. Arthur Reavell, M.I.M.E.

Jan. 16. Society of Chemical Industry, *Edinburgh and East of Scotland Section*. Medical Chemistry Class-room, University Buildings, Teviot Place, Edinburgh, at 7 p.m. "The Chemistry of the Genus Eucalyptus," by Prof. R. Robinson, D.Sc., F.R.S.

Annual Informal Meeting, in the Tutorial Class-room, Medical Chemistry Department, the University, Teviot Place, Edinburgh. "The Combustion of a Volatile Hygroscopic Liquid," by Mr. J. B. Shoesmith, M.Sc.

Jan. 17. Society of Chemical Industry, *Nottingham Section*, and Society of Public Analysts, at University College, Nottingham, at 7.15 p.m. Joint Discussion on "The Detection of Small Quantities of Arsenic," opened by A. Chaston Chapman, F.R.S.

Jan. 17. The Industrial League, Caxton Hall, Westminster, S.W., at 7.30 p.m. "A Talk about Economics," by Sir Ernest Benn, Bt.

Jan. 17. Royal Society of Arts, John Street, Adelphi, at 8 p.m. "Hygienic Methods in Painting," by C. A. Klein.

Jan. 18. Institute of Mining and Metallurgy, Geological Society's Rooms, Burlington House, at 5.30 p.m. "Note on an Apparatus for Small-Scale Flotation Tests," by H. L. Sulman and H. F. K. Picard.

Jan. 19. Institution of Mechanical Engineers, Storey's Gate, London, at 6 p.m. "Problems of Engine Indicators," by L. Pendred. "New Form of Optical Indicator," by Prof. F. W. Burstall.

Jan. 19. Society of Chemical Industry, *Liverpool Section*, in the Muspratt Lecture Theatre, the University, Liverpool, at 6 p.m. "Patent Fuels," by Arthur Grounds, B.Sc.

Jan. 19. Society of Dyers and Colourists, *Manchester Section*, 36, George Street, Manchester, at 7 p.m. "The Behaviour of Titanium Hydroxide towards Dyestuffs," by Dr. J. K. Wood and A. M. Morley. "Investigations on the Constituents of Raw Cotton, IV.," by Prof. E. Knecht and G. H. Streat.

Jan. 22. The Institution of Rubber Industry, Midland Hotel, Manchester. "Patents: As they Affect the Rubber Industry," by H. E. Potts, M.Sc.

Jan. 26. Royal Institution, Albemarle Street, W., at 9 p.m. "The Machinery of Anti-Bacterial Defence," by Sir Almroth Wright, K.B.E., etc.

NEWS FROM THE SECTIONS

SOUTH WALES SECTION

The fifth ordinary meeting was held on December 15, at the Technical College, Swansea, with Professor C. M. Thompson in the chair, and Mr. T. A. Goskar read a paper on "Peat."

Mr. Goskar first discussed the mode of formation and occurrence of peat, and emphasised the difficulty of removing the 90 to 95 per cent. of water contained in the raw material, if conversion into briquettes was desired. Methods which have been tried in the past for drying peat were shortly described, the Ekinburg wet-carbonisation process in some detail. On mixing a small proportion of gritty dust (peat charcoal or coal) thoroughly with peat, and slowly applying a pressure of 2 tons per sq. in., the moisture content could be reduced to about 50 per cent. by one pressing, the remaining moisture being reduced to 8 per cent. by air-drying for 24 hours. Because the hydrocellulose had not been destroyed, material obtained in this way yielded hard briquettes, and also harder coke than that from peat in which the hydrocellulose had been destroyed, as in the Ekinburg process.

Other peat products were described, such as peat-moss litter, peat dust for disinfecting, paper and cardboard (insect and damp-proof), ammonia, alcohol, fuel oil, and charcoal or coke. The coke could be made soft or very hard at will (harder than coke-oven coke), and of specific gravity from 0·75 to 1·4; it was of exceptional quality for the iron-smelting industry, and the hard coke would sustain a greater burden in the blast-furnace than the hardest coke from coal. Charcoal of exceedingly fine quality for hardening steel could also be made.

Success in the peat industry was to be looked for in the production, not of the briquettes of low calorific value which have so often been the final product, but the more varied and valuable substances mentioned. A short discussion followed, and specimens were shown.

BIRMINGHAM AND MIDLAND SECTION

At the meeting held on December 19, Mr. A. E. Tucker, F.I.C., read a paper on the physics and chemistry of metal colouring.

Mr. Tucker showed many specimens of ordinary colouring in which the effects were produced by the deposition of minute amounts of other metals or by the alteration of the surface by etching, as in the case of French or Japanese art-work, etc. It was pointed out that the beauty of many such articles lay in their colouring, and also that a good deal of the commercial success of many foreign metal goods arose from their high finish in this respect. Such finish was often obtained by a very small outlay, but it implied much experience and technical knowledge. Demonstrations were given of new electrolytic processes—the Testini-Rondelli processes—in which no foreign metal was used for obtaining the colours, which depended solely on the alteration of the surface of the metals of which the goods were made. No measurable alteration was produced, and so the processes were applicable to the most delicate measuring instruments. In consequence, metal in the form of sheets, etc. could be worked up after such colouring without any scaling or other disturbance of the surface. The hardness of the surfaces produced and, in the case of iron, the increased resistance to rusting, were demonstrated by means of specimens produced on a large scale. Apparently, hitherto unknown oxides of extreme thinness were formed on the metals treated. After discussing the chemistry of the colour formation it was shown that the varying stages of treatment could be clearly indicated by means of electrical measuring instruments, so that very little experience was required for working the processes, which became routine production work, the output for a given plant being very high.

LONDON SECTION

"Micro-organisms and their Application to Industry and Research" was the subject of a discussion at a meeting held jointly with the Biochemical Society in the Institution of Mechanical Engineers on January 8, Mr. A. Chaston Chapman, F.R.S., presiding. In opening the meeting Mr. Chaston Chapman reviewed the industrial applications of microbiology, and said that the fermentation industry was in a backward state. The plea was renewed for the establishment of a National Institute of Industrial Microbiology, which should be a centre of research, provide specialised training, produce pure cultures, and constitute a home for British microbiological science.

Sir W. J. Pope, who opened the discussion, referred to the variety of organic compounds produced by micro-organisms and expressed surprise that the chemical mechanism of the cell—a subject for pure organic chemistry—had been so little studied by chemists. In view of the ever-growing cost of fuel and labour, the ability of micro-organisms to utilise low-potential solar energy and thus produce organic compounds very cheaply was most important. Many compounds could be produced by bacterial activity but the processes had not been properly worked out. More study of the chemical activity of micro-organisms would give results of far-reaching importance and he supported the suggestion that the foundation of a National Institute of Industrial Microbiology was desirable.

Prof. Gowland Hopkins also emphasised the great variety and cheapness of the chemical actions induced by micro-organisms. Some bacteria contributed but few products to the medium in which they grew, but by "educating" them more products could be obtained. Many of the products were intermediate, not end, products and would normally undergo further change in the cell. If the permeability of the cell were modified, and if the many species available were utilised, the already great variety of products could be increased. By selecting from an average population, special individuals could be obtained capable of carrying out reactions which the original culture could not perform. The selection of micro-organisms offered vast possibilities.

Prof. A. Harden said that no really quantitative work had been done on the chemistry of the changes produced by micro-organisms. Despite the range of products obtainable, there was practically always a stage at which most organisms yielded the same compound when acting on the same substance. Thus acetaldehyde was probably a preliminary product of the action of yeast, *B. coli*, the lactic-acid and many other organisms, on sugars. This suggested that there were only one or two ways of attacking the sugar molecule. To reduce complications due to growth, the need of food, etc., the possibility of utilising dead organisms required investigation.

The agricultural importance of micro-organisms was dealt with by Sir J. Russell. After describing the preservation of greenstuff by acetic acid produced by fermentation and the fermentation of cellulose to give methane and hydrogen (used for heating) or artificial manure, the various forms of nitrogen-fixing bacteria were discussed, and it was pointed out that although so much attention had been devoted to chemical processes for fixing nitrogen, nothing was known of the mechanism by which organisms could fix atmospheric nitrogen at low temperatures in the soil.

Prof. H. E. Armstrong opposed the proposal to found an Institute on the grounds that it would lead to centralisation and sterilise original work. What was wanted was work in purely organic chemistry. Mr. Chaston Chapman in reply supported the foundation of the Institute because the industrial applications of microbiology required study and this would lead to true organic chemistry through research on the cell.

The manufacture of antitoxins was described by Prof. G. Barger, who observed that Buchner's work on zymase required extending with the object of producing a solution of an organism which showed properties not possessed by the organism. An account of micro-organisms in the tanning industry was given by Dr. R. Pickard, who said that many problems still awaited solution, and that nothing was known of how tannin was produced in the tree, although enormous quantities of tannin were imported, only a small amount coming from the Colonies. Dr. Tyson claimed that an Institute for general microbiology would be preferable to one for industrial microbiology. Mr. E. R. Bolton spoke on the importance of microbiology in the manufacture of margarine, and Dr. R. Armstrong discussed the variability of micro-organisms, and suggested it was due to inheritance and segregation on Mendelian lines. In conclusion the meeting resolved that the foundation of a National Institute of Microbiology was desirable in the public interest.

PERSONALIA

Mr. H. S. Taylor has become professor of physical chemistry in Princeton University, U.S.A.

Dr. K. Fredenhagen has succeeded Prof. A. Sieverts as professor of physical chemistry and director of the school of chemistry of the University of Greifswald, and Dr. R. Pummerer has succeeded Prof. J. Meisenheimer in the chair of chemistry in the same University.

On December 20, Sir Max Muspratt, chairman of the United Alkali Co., Ltd., was entertained to dinner by representatives of the company's staff as an expression of pride in the honour conferred upon him by the King. Mr. T. W. Stuart, general technical manager, presided over the dinner. A piece of plate was presented to Sir Max as a souvenir of the occasion.

* * *

With regret we record the death on January 3, of Dr. Georg Lunge, aged 84 years, emeritus professor in the Federal Polytechnic, Zürich, and well known for his work on technical methods of chemical analysis.

MEETINGS OF OTHER SOCIETIES

INSTITUTION OF PETROLEUM TECHNOLOGISTS

At the meeting held on January 9, Dr. W. R. Ormandy and Mr. E. C. Craven contributed a further account (*cf.* J., 1922, 30 R) of their investigations into the physico-chemical significance of flash-point temperatures. The work described was part of the extended investigation on the physical properties of pure and mixed fuels undertaken at the joint request of the Distillers' Co., Ltd., and the Fuel Research Board. Heptane, toluene and ethyl alcohol were utilised as experimental material and the chief properties investigated were vapour tensions, flash-points at reduced or increased pressures, flash-points in mixed gases, and the effect of increasing temperature on the flash-points. Previous work had shown that at the flash-point in air all hydrocarbons possess approximately the same vapour tension, that increase of pressure raises the flash-point, and that the flash-point is lowered on replacing the air by oxygen. The present work was mainly an account of further investigations on these relations. The methods and apparatus used were described in detail, and numerous tables of vapour pressures and flash-points obtained under various conditions were given.

The importance of this work depends on the suggestion that from the determination of the vapour tension of a mixture of hydrocarbons at any temperature and pressure, it should be possible to deduce the point at which an explosive mixture of the vapour and air will be formed at some other temperature and pressure; so that the conditions for utilising the liquid as fuel in an internal-combustion engine could be rapidly calculated from the results of one or two experiments.

INSTITUTION OF RUBBER INDUSTRY

A meeting was held in Birmingham on December 20, when Mr. B. D. Porritt, M.Sc., read a paper on "Some Aspects of Science in the Rubber Industry," and introduced the subject by stating that Priestley, for many years an inhabitant of Birmingham, was the first to suggest the use of rubber for erasing pencil marks.

In most industries the output usually consists of a limited number of standard products manufactured from simple raw materials by processes that are generally to a great extent automatic. No such simplicity characterises the rubber trade. For example, a factory manufacturing spread goods will probably utilise over 100 formulæ composed of innumerable different ingredients, and keep a stock of cloths of every conceivable width, weight, and colour to provide the endless combinations required to satisfy popular fancy. The present lack of standardisation in the products of the industry is possibly detrimental both to manufacturer and consumer, but a body such as the Institution of Rubber Industry, which brings both parties into personal contact, may be preparing the ground for a better understanding in the future. There are few important industries which call for a greater proportion of skilled supervision and a higher standard of ability on the part of the individual than the rubber trade, not only on account of the variety of its materials, processes, and products, but also from the fact that the fundamental principles underlying its methods are as yet imperfectly understood.

After defining the term "science" in the widest sense as implying not only the possession of abstract knowledge, but also the power to apply it to some useful purpose, the lecturer discussed the technical direction of the rubber factory, emphasis being laid on the need for specialised knowledge. The works chemists and engineers are fully occupied in keeping production running smoothly, and the pressure of this onerous routine work is probably responsible for the fact that the technique of the industry has been so little altered since the time of Thomas Hancock, some 80 years ago. It is now time for greater use of technical research in the works, and with the co-operation of the chemist, the engineer, and the accountant, a systematic attack might be made on many sources of wastage of power, steam, time, and material to which the methods of manufacture in the rubber industry specially lend themselves.

To achieve success in such efforts a higher standard of education will be necessary for those who supervise the work of the factory departments. In this connexion, a series of popular lectures on rubber and rubber testing, for the benefit of the factory foremen, might be a profitable expenditure of time on the part of the chemist as a means of securing the interest of the practical man; and provision for the future might be made by filling works vacancies from promising junior assistants engaged on routine testing in the laboratory. The chemist can also be employed usefully on the commercial side of the works, as is done in the dyestuffs industry, and the physicist is becoming an important ally of the chemist in industrial laboratories. More attention, however, will have to be paid to the physical efficiency of the factory worker, and the services of the physician and dentist should play a greater part in the economy of the factory, whilst the technical staff could ensure that the conditions of work are such as to minimise fatigue and eliminate eye-strain.

In every industry scientific control is slowly but surely displacing rule of thumb methods, and machinery being substituted for hand work. These changes point to an increasing need for a high standard of technical efficiency in the administrative staff of a works and a higher level of education amongst the workpeople. To fill its technical posts, the rubber industry will have to look primarily to the universities and technical colleges for its "raw material." The importance to the industry of a supply of men combining scientific knowledge with technical experience has not been overlooked by the Council of the Institution of Rubber Industry, and the Honorary Technical Advisers are at present considering a scheme for providing a "hall mark" for all who have attained the necessary standard of proficiency. Whilst this scheme will help the manufacturer to select his technical staff, and indicate to the student the course of study he should follow, it will not in itself solve the problem of the supply of suitably qualified men, and for this reason it will be in the interest of the rubber trade to encourage and support any institution which affords opportunities for post-graduate research on its special problems and instruction in its technical methods. Hitherto, industries have relied largely on the universities for the development of the pure science which forms the basis of their technical practice, and in many cases this confidence seems to have been justified. Research in rubber, however, apart from its fundamental difficulties, can scarcely be undertaken without expensive experimental plant, and, in consequence, this otherwise attractive subject has received scant attention from the scientific world, whilst the results of what little work has been done are often almost valueless owing to the absence of information regarding the composition and methods of preparation of the samples employed.

The existence of the Institution of Rubber Industry is itself a proof that the conservatism of the past is rapidly disappearing, and the formation of a Research Association is a striking illustration of the importance now attached to trade co-operation in matters of fundamental importance. It is increasingly apparent that the future development of the rubber trade must lie mainly in the many potential markets overseas, in which the competition of other nations must be met by enterprise and up-to-date methods. To secure the position in the world's markets, therefore, to which his pioneer work would seem to entitle him, the British manufacturer will from now onwards have to make the fullest use of every aid which modern science can offer.

SCIENCE MASTERS' ASSOCIATION

(*From Our Special Correspondent*)

The meeting of this body, this year, at Cambridge, from January 2 to 5, has been remarkably different from other educational conferences. Instead of indulging in vaporous talk about "the glue which holds society together," still less of engaging in "research" into the value of the vulgar cinema-show, the science masters have abandoned themselves during a couple of days to intellectual debauchery of the highest order, thereby following the precedent set two years ago at Oxford. About three hundred members were present; they found agreeable lodging and refreshment in Trinity and St. John's Colleges.

It has been the custom of the Association to choose as President, each year, a scientific worker of distinction. This year, the President was Sir Ernest Rutherford, who delivered his address at the opening meeting on Tuesday evening. Very wisely, he said little on school politics; instead, he gave a most entrancing original discourse, tracing the historical development in the field of discovery he has made so entirely his own, and in which he is now the acknowledged leader. A modern knight errant, armed with the α-particle, an ultra-microscopic missile moving with incredible velocity, ho is steadily bombarding various elementary molecules, apparently with success in some cases: shattering them to their downfall into simpler materials; not knocking mere spots off them, but substantial hydrogen atoms. Speaking in simple and homely terms, clearly moved as he was by absolute honesty of purpose, with no desire to exaggerate or overclaim, on the contrary, always counselling caution, his address must have been a revelation to all who could appreciate the argument and its intricacies, and fathom the intensity of thought with which Sir Ernest has carried on his work. The simplicity of the methods used in arriving at results of an altogether transcendental character is most surprising; a more perfect illustration of the truly scientific use of the imagination could not have been given, perhaps never has been given. Had the Association enjoyed this opportunity alone, the visit to Cambridge would have been sufficiently rewarded.

It is worth while to think back to the days when the chemist Crookes was determining the atomic weight of thallium and observed a peculiar behaviour of his balance. This led him to the study of the electric discharge under greatly reduced pressure and at last to his epoch-making observations on the negative discharge. A wondrous structure of discovery has been built upon the foundations thus laid, and in place of the vague, perhaps unscientific, surmises of Crookes, we now have not only clear mass conceptions but are definitely started on the quest into the very structure of the atoms themselves—in no way an idea which is new to us, yet one which we had scarcely thought would be open to practical solution. That simple ballistic methods could play so great a part in chemistry was scarcely to be imagined as possible.

On Wednesday morning, a lecture was delivered by Professor Seward, on "A Summer in Greenland," and in the afternoon, Mr. A. Wood and Mr. F. C. Potts lectured simultaneously, the former on "The Acoustics of Public Buildings"; the latter on "Coral Reefs in the Pacific." In the evening, Sir William Pope gave an illustrated lecture on "Crystalline Liquids."

Thursday was a similarly crowded day. First, Sir J. J. Thomson discoursed on "The Electron in Chemistry." The afternoon simultaneous lectures were by Dr. Hartridge on "Physiological Limits to the Accuracy of Visual Measurements" and by Mr. E. K. Rideal on "Molecular Orientation on Plane Surfaces." At night, Mr. P. E. Priestly lectured on "Antarctic Exploration with Shackleton and Scott," during the course of a conversazione.

Sir William Pope's lecture was delivered with his well known lucidity and illustrated by a wealth of appropriate lantern demonstrations. He not only showed that the term "liquid crystal" is a misnomer but also gave a clear lead to the interpretation of the doubly refracting power of many liquids, suggesting that its origin might be found in the presence of complexes of associated molecules.

Sir J. J. Thomson came forward not as Master of Trinity but as Master Builder—as accoucheur of the Electron, the spermatic origin of which is to be found in Crookes's negative glow. He modestly said nothing of its delivery but much of its upgrowth and of the possible vagaries of its behaviour in association with nuclei of various dimensions. Necessarily, the arguments were highly speculative and they were not unduly controlled by facts. At the outset, the Master had something to say of the difference between chemist and physicist, without making it clear wherein it lay. The question may well be asked, whether there be any real difference. Is not the physicist perhaps the chemical Prodigal Son come home—with much to learn of the happenings since his departure In early days, when physics was taught with understanding and so that it could be understood by persons of moderate intelligence, it was taught as a branch of chemistry by the chemist. *Miller's Chemistry* was in three volumes and the first was devoted to *Chemical Physics*. It is a moot point, whether most so-called physical changes be not all changes involving alterations in molecular character or configuration—the changes in water certainly are; so perhaps are those involved in the production of an electric current by the revolution of a copper disc in a magnetic field. In fact, outside mechanics—which scarcely belongs to physics—and perhaps sound and some parts of light—which may well be regarded as belonging to mechanics—most physical phenomena are interlocked with those of chemical change. The electron is certainly the foundation stone of both physics and chemistry. The physicist would seem to be mainly an incomplete chemist, one afflicted not with water but with mathematics on the brain and possessed of a highly developed mechanical sense. The physicist is only beginning to distinguish atoms from molecules and developing a sense of molecular structure; his knowledge of the conditions which determine chemical change is nil—though in this latter respect, the average chemist is not much ahead of him. It was interesting to hear Sir J. J. Thomson talking of hydrogen and oxygen, as though it were possible to bring about their direct interaction; but doubtless, someday, the discharge of electricity through gases will be studied rationally, with due regard to the chemist's susceptibilities, not thought of as a mere drive of electrons.

Dr. Rideal's lecture was a lucid and comprehensive survey of recent inquiry, excepting that he omitted the section so largely developed by Cambridge workers, Hardy especially, that of lubricants. It was delivered with striking fluency and must have been of great interest to those to whom the subject was new. The tendency to romance was not altogether absent from the latter part of the discourse; but we learn most by going ahead, and the salt of scientific caution is a condiment, the taste for which mostly comes with age.

It is remarkable that problems of structure were dealt with in all four chemical discourses to which the science teachers listened. There is little doubt that the time is come to change Wurtz's well known definition into one of wider import. Chemistry, in all its ramifications, is now the Science of Molecular Structure, not merely a French science.

In addition to the lectures, various laboratories were open to inspection and many special demonstrations were given by leading members of the staff. The value of the visit, the stimulus it will be to teachers, must be very great; and many will have realised, more than they ever did before, what they are called upon to do by way of preparing their pupils to make proper use of the opportunities Cambridge will afford to them.

To spend such days in the University must have been an extraordinary revelation to not a few—the greatness of the school cannot but have impressed them; the evidence of activity and of progress was overwhelming. One grave mistake was made, however: the opportunity was lost, which the meeting afforded, for a discussion, between the University authorities and the teachers, on ways of breaking through the vicious circle within which the two parties have long been helpless wanderers. The University governs the schools, through its scholarship examinations, which are undeniably of a wrong type. Science, thus far, has been a practical failure in the schools, in no small degree because of the influence the examinations have had upon the teaching; on the other hand, as proper foundations cannot be laid under the present system in the schools, the teaching does not advantage the University.

CORRESPONDENCE

PRICES OF GERMAN BOOKS

Sir,—In a recent letter to *Nature* (Dec. 23, p. 845) I drew attention to the scandalous prices of German books. As some members of the Society of Chemical Industry may not have seen this communication, I wish to call attention to it in your columns, as it is only by united action that the perpetrators of this swindle can be suitably dealt with. There has been much comment in this country and in America on this subject, particularly by Prof. Noyes in the *Journal of Engineering and Industrial Chemistry* (1922, 99), and in editorial comments in the same Journal (1922, 475), from which the following is extracted:—"If there be any who still favour former sources for literature let them consider the last edition of Beilstein. There are to be seventeen volumes. To those who subscribed for the set, Volumes I and 2 were sold for $12 for the two. Volume 3 has appeared at $18, and it is understood that Volume 4 will cost about $28. Volume 17 . . . . !!! "

In this connexion, the attached correspondence may be of interest, bearing in mind the following prices, from the *Berichte* of July, 1922, charged to members of the German Chemical Society:—

	Beilstein				Stelzner		
	Bound volumes				Unbound volumes		
	I	II	III	IV	I	II	III
England, shillings..	40	38	102	110 ..	24	38	100
Germany, marks ..	110	110	280	330 ..	70	104	325

The subscriptions show a similar distinction, the charges being 10 marks for Germany, $2 for the United States, and 10s. for England. I wrote as follows to the Treasurer of the German Chemical Society, on October 31, 1922:—" Sir, I notice that members of the German Chemical Society who do not live in Germany are charged a much higher rate for their subscriptions than those who do reside in Germany. I also note that the charges for successive volumes of Beilstein are also much higher, and are steadily increasing. Much dissatisfaction has been expressed at this state of affairs, and I shall be glad, with others, to learn whether it is proposed in the future to maintain such a distinction in the charges made to various members, as I am sure you will agree that, under the present circumstances, it is not worth while for chemists living outside Germany to continue to belong to the German Chemical Society."

The reply, in translation, runs as follows:—" In answer to your letter of October 31, addressed to our Treasurer, the questions put by you have already often been discussed with our foreign members, including your countrymen, and we would refer you to the protocol of the general meeting of last year published in the *Berichte*. The prices of our journals were fixed after thorough discussion; they are not much higher than in 1914; and, in the case of the *Centralblatt*, are actually lower. Reckoned on the number of pages, the prices are much smaller than those of the publications of almost all foreign chemical societies. *The justice of our fixed prices was confirmed a few days ago from Switzerland.* [The italics are mine.] There can be no thought of making German and foreign prices equal so long as we Germans are compelled to spend unnumbered thousands of our depreciated marks to obtain English books. In relation to Beilstein I can assure you that a further rise in price of the volumes which are to appear in future will not occur. Finally, we may remark that many of our members in countries whose currency has depreciated little, appear to see things differently from you, for the number of foreign members is steadily rising. (signed) Dr. Jost."

It is amusing that Dr. Jost refers proudly to the bulk of his journal, which enhances its value so much in German eyes. The diffuseness of German publications is considered, in most countries, to be a disadvantage: recent complaints were about the quality, not quantity. The remark about Germans having to spend many marks to purchase foreign works is typical of Bosch mentality: they need not have printed such a lot of paper money. Was there not an article in the Treaty of Versailles by which Germany undertook not to impose on British subjects any other, or any higher, direct or indirect fees, dues, or taxes than are imposed on German citizens? Under the circumstances I am sure most chemists will agree that, until treaties with our recent enemy are something more than scraps of paper, money spent in subscriptions to the German Chemical Society is not much better expended than in buying their fraudulently depreciated paper marks. It is to be hoped that the English and American Chemical Societies will soon be in a position to publish a Dictionary of Organic Chemistry and other necessary works, at a fixed, reasonable price and in a terse and civilised language,—I am, Sir, etc.,

K. C. Browning.

Hammersmith, W. 6.
Jan. 1, 1923.

THE EXTRACTION OF GASOLINE FROM NATURAL GAS

Sir,—I wish to draw your attention to a mistake on page 525 r of the issue for December 15, 1922, ninth line from bottom of second column, where "James Young of Clippen, England," should read "William Young of Clippens Oilworks, near Paisley, Scotland.

James Young was known as Paraffin Young, and later became Sir James Young. He was the first to distil shale for mineral oil at Bathgate, Scotland, about 1850, Young's Mineral Oil Co. being formed subsequently.

In 1881, at Clippens Oilworks, a very small quantity of gasoline (there was then very little sale for it) was recovered from the spent gases from the shale retorts. Most of the spent gas was burned under the oil stills and steam boilers, and also through 2-in. vertical pipes to give light to the men charging the retorts, etc. I was engineer and draughtsman there. Mr. William Young was then experimenting with a new vertical retort for continuous distillation of shale. I made the drawings of the retort for the Patent Office, and this retort, later known as Young and Beilby's retort, gave fresh life to the shale-distillation industry. A lot more could be said on the subject, but I think this correction is necessary.—I am, Sir, etc.,

George Valentine, F.C.S.,
Chemical Engineer.

Research Laboratory,
13, Farm Avenue.

Dec. 28, 1922.

NEWS AND NOTES

FRANCE

Industrial Notes

Metallurgy.—Prices of metallurgical products show a steady upward tendency, largely owing to the proposed rise in the price of coke and the dearth of scrap ferrous metals. Stocks of scrap ferrous metals are very much depleted owing to the growing demand from abroad: during the first ten months of 1922, 791,823 metric tons of scrap was exported, as against 547,645 m.t. during the whole of 1921. To meet this serious situation a decree, dated December 29 last, has been issued prohibiting all such exportation. It appears that in certain cases special export licences will be granted, particularly for consignments to Italy.

Chemical Industry.—Constant fluctuations in the money market make the transaction of business very difficult, owing to the difficulty of establishing cost and selling price with any degree of accuracy or certainty. Under such conditions business becomes a sort of gambling. Noteworthy is the shortage of sodium sulphate, which is very scarce, partly because several glass-factories in Belgium have been started again, and partly because the production of this chemical has suffered of late from the poor market that exists for hydrochloric acid, the by-product of its manufacture. Arsenious acid also is in short supply; deliveries are much delayed, and as the quantity available is small, prices have soared up to extraordinarily high levels. Many works are contemplating starting work again just to profit by the high prices. There is also a keen demand for antimony salts, especially for sodium antimoniate. Wood-distillation products tend to become scarcer every day, acetone being almost unobtainable. Stocks of acetone at consumers' works cover the next eight or ten months, and its price has more than doubled in the course of only a few weeks; consequently prices of acetic acid and the various acetates have increased in proportion. There is also a very good demand for methyl acetate and methyl alcohol; in fact, the methyl-alcohol industry, which about a year ago was seriously depressed, is now very prosperous.

GERMANY

The Health of Lead Workers

From an investigation into the measures for protecting the health of workers in lead-colour factories and of painters in Germany, K. B. Lehman (*Zentralbl. f. Gewerbehyg.*, 1922, **10**, 2) concluded that great care was taken to protect the workers. Approximately 70 to 75 per cent. of the workers displayed no distinct signs of lead-poisoning, although the age of 27 per cent. was 50 years. The cases of sickness and sick days have fallen from 15 per cent. and 3·3 sick days in the period 1912-1914 to 3·6 per cent. and 0·75 days in 1919-1920. This improvement is ascribed to the manufacture of pulp lead instead of lead ground in oil, dust protection, mechanical packers, educating the workers, and other measures due to legislative action, as well as to greater care in the diagnosis of lead poisoning. It is concluded that the dangers to white-lead workers have decreased, but could be still further reduced; and that painters run much less risk than appears from many statistics.—(*J. Ind. Hyg.*, *Nov.*, 1922.)

UNITED STATES

Production of Minerals and Metals in 1921

The United States Geological Survey has issued a preliminary summary of the country's mineral production in 1921. The following statistics show the output of metallic minerals and metals and of mineral products used in chemical industry:—

		1921	1920	Inc. (+) or dec. (—) per cent.
Gold	Fine oz.	2,422,006	2,476,166	— 2
Silver	,,	53,052,441	55,361,573	— 4
Platinum and allied metals	,,	56,370	41,544	+36
Aluminium	Value, dollars	10,906,000	41,375,000	—74
Antimonial lead*	Short tons	10,064	12,535	—20
Antimony	,,	1,589	2,785	—43
Bauxite	Long tons	139,550	521,308	—73
Cadmium	lb.	65,101	129,283	—50
Chromite	Long tons	282	2,502	—89
Copper	,,	225,708	539,733	—58
Iron ore	,,	26,652,528	69,281,341	—62
Iron, pig	,,	16,000,000	35,710,227	—55

Talc and soapstone	,,	126,434	210,635	—40
Total value	dollars	4,056,000,000	6,951,410,000	—42

* From domestic and foreign ore. † Acid of 60 Bé. from copper and zinc smelters, including 23,728 t. of stronger acid, not converted to 60 Bé.

Statistics of the production of crude ores of copper, lead, copper-lead, gold and silver, zinc, etc. in 1921 are not yet available.

GENERAL

Honour to Senator Paternò

As Prof. Paternò will attain his 75th year in May, a committee of the Italian Association for Pure and Applied Chemistry has been formed under the presidency of Prince Ginori Conti to celebrate the occasion. In order to place on record the esteem in which Prof. Paternò is held both at home and abroad, the Committee has decided to raise a fund for the purpose of providing a "Paternò Medal," to be awarded annually, without distinction of nationality, to the author of the most important discovery in the field of chemistry. Subscriptions should be sent to Prof. D. Marotta, Associazione Italiana di Chimica Generale ed Applicata, Via Tre Novembre, 154, Rome, 1.

Industrial League and Council

This organisation, which has the object of improving the relations between employers and employed, has arranged for the following lectures on industrial topics to be given in Caxton Hall, Westminster, S.W. 1, on Wednesday evenings from January 17 to March 28, at 7.30:—Jan. 17, "A Talk about Economics": Sir E. J. P. Benn; Jan. 24, "Education as a Function of Management": H. H. Elvin; Jan. 31, "Industrial Liberty": Sir A. R. Holbrook; Feb. 7, "Some Obligations of Industry to Labour": F. O. Roberts; Feb. 14, "Home and International Labour": Sir L. Macassey; Feb. 21, "Economics of War and Peace": W. A. Appleton; Feb. 28, "Fundamental Causes of Unemployment": H. G. Williams; Mar. 7, "Control of Industry": A. Dalgleish; Mar. 14, "Functions of Works Committees": J. Murray; Mar. 21, "The Fallacy of Low Wages": T. E. Naylor; Mar. 28, "The Function of Capital": E. J. Garmeson. Admission to the meetings is free, and all those interested in these industrial subjects are invited to attend. Information on the work and objects of the League can be obtained from the General Secretary, 82, Victoria Street, London, S.W. 1.

German Research Institute for Fibre Chemistry

The dedication ceremony of the Kaiser Wilhelm Institut für Faserchemie at Dahlem, Berlin, was held on December 5. The textile industry, which forms such an important part of the national resources, has hitherto been but poorly represented as a co-ordinated unit in Germany's system of technical education, the branches of spinning and weaving being divided up between mechanical institutions and the departments of dyeing and finishing between chemical institutions. At the new research institute it is proposed to unite all the branches into an organised system for the study of the fundamental scientific problems of the inter-related fibre industries. The new building has been erected in close proximity to the parent Kaiser Wilhelm Institute. Preliminary activity extending over three years has already borne important fruit in the establishment of new methods of research, in particular the epoch-making discovery, by means of the Röntgen rays, of the crystal-like arrangement of all organised natural structures. Scientific treatment of the technology of all industries has its foundation in numerical standards and these will be established in intimate relations from the fibre to the yarn and from the yarn to the fabric, beginning with systematic researches on the industrial manipulation of the wool fibre.

OFFICIAL TRADE INTELLIGENCE

(From the Board of Trade Journal for January 4)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina ..	Drugs, etc.	6920/F.L./C.C.
British India ..	Dry paint (tender for)	*
Canada.. ..	Drugs, soap	†
,, ...	Sodium sulphate	10174/E.D./C.C.
France	Gum arabic, gum lac	10
Mexico ..	Chemicals	25
New Zealand ..	Porcelain insulators	10267/E.D./E.C.
Serbia	Drugs (tender for)..	9733/F.E./C.C.
South Africa ..	Varnish, paint, iron and steel ..	3
,, ..	Industrial raw materials	4
Spain	Tinplate, soldering tin	16
,, ...	Fertilisers	17
United States ..	Tiles..	17824/F.W./M.C.

* Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1.

† Canadian Trade Commissioner, 73, Basinghall Street, E.C. 2.

TARIFF CUSTOMS EXCISE

Australia.—In the issue for January 4, the attention of exporters is drawn to the protection of preference granted to goods from the United Kingdom.

Austria.—Increased customs duties are payable on beet and cane sugar, invert sugar, starch, grape, milk and other sugars, mineral, lignite and schist oils, vaseline, lubricating greases, perfumery, etc.

France and Algeria.—The duties have been increased on certain chemicals, tin, iron, and various paper products, and decreased on ferromanganese, ferrosilicon, plate glass, dextrin, magnesium chloride and sulphate, lead acetate, potassium and sodium chromates and bichromates, etc.

Germany.—New rates of monopoly tax have been applied to imported spirits, alcoholic products, ether and products containing ether.

Hungary—Latvia.—A commercial treaty has been concluded between these two countries.

Madagascar.—An import duty has been applied to ammonium sulphate.

Mexico.—Various fibres are affected by recent modifications of the import tariff.

Nyasaland.—Under the revised tariff the rate of import duty on cement, motor fuels, lubricating oils, and iron has been reduced to 15 per cent. *ad valorem*; drugs of the British Pharmacopœia imported by persons licensed to sell drugs and poisons, and printing inks have been added to the list of free goods; and the export duty on beeswax has been abolished.

South Africa.—Regulations have been issued prohibiting the importation, exportation, sales, etc. of specified habit-forming drugs or raw materials from which they can be extracted, except by authorised persons and under licence.

LEGAL INTELLIGENCE

ALLEGED DETERIORATION OF A DISINFECTANT IN THE TROPICS. *F. A. Langley* v. *The Milton Manufacturing Co., Ltd.*

In the High Court on December 18, Mr. F. A. Langley, trading as Langley, London, claimed damages against the Milton Manufacturing Co., Ltd., for alleged breach of an agreement under which the plaintiff undertook to market the defendant company's disinfectant "Milton" in South America, as well as damages for breach of warranty as to the quality of the disinfectant supplied.

Under the agreement, the defendant company undertook to sell "Milton" to the plaintiff at a minimum export price f.o.b., London, less 5 per cent., and commission for sale in Chile, Bolivia, Ecuador and Peru. Plaintiff sent an agent over to S. America to prepare the market for the goods, but the defendant company supplied goods that were not of the quality, strength, or description represented, and wholly worthless. The "Milton" was so weak that it would not remove ink stains on paper or fabrics; it failed to dissolve a piece of sponge; and, in fact, it was more than 40 times weaker than "Milton" of normal strength. In consequence, the goods could not be sold, and the plaintiff had not only lost profit but also money spent on advertising, freight, insurance, warehousing, etc. "Milton" was usually sold in brown bottles, but that shipped to plaintiff was in green bottles, and in hot countries the strong light had a deteriorating and disintegrating effect upon liquids such as "Milton." The defendant company wrote regretting that the disinfectant had been put in green bottles, as that might have had an adverse effect, and they offered to replace the whole of the shipments at their own cost.

Mr. R. H. Grimwood, analytical chemist, said he had analysed samples of "Milton" in green and in brown bottles. That in green bottles had no effect upon ink stains, whereas that from brown bottles removed it at once; the former also failed to dissolve sponge, but the latter dissolved it in less than 48 hours. Chlorine was the active ingredient in "Milton," and when he analysed the samples he found that those in green bottles contained only 0·012 per cent. of chlorine, whereas those in the brown bottles contained 1·08 per cent. He did not consider that the hot climate of South America would affect the disinfectant; and the question of actinic quality of the glass was not very relevant.

For the defendant company it was claimed that there was no warranty of any kind. The contract was f.o.b., London, and the disinfectant was perfectly good when shipped, so that what happened to it afterwards was of no importance. The company had sold over £20,000 worth of "Milton" in green bottles without a complaint, and none had been returned during the six years they had sold it.

In giving judgment, Mr. Justice Branson said that the plaintiff was suing the defendant company for breach of agreement, by virtue of which he was appointed for three years as its distributing agent in South America. He accepted Mr. Langley's account of what took place, and it followed there was a warranty that the goods were fit for importation in the countries in question. This warranty had been broken, and he therefore gave judgment for the plaintiff for £1630, and granted a stay of execution on the usual terms.

REVIEWS

The Petroleum and Allied Industries. *By* James Kewley. *Industrial Chemistry Series, edited by Dr. S. Rideal. Pp.* 302. *London : Ballière, Tindall and Cox,* 1922. *Price* 12*s.* 6*d. net.*

The large oil companies have for some time past appreciated the advantages which their non-technical staffs would derive from some general knowledge of oil production, oil products and their uses, and this led in the first place to the organisation of special lectures, and to the development of systematic instruction in petroleum technology elsewhere. Mr. Kewley has taken an active part in both, and in the preface to this volume he states that the book is primarily intended for non-technical employees of the companies among whom " there exists a very commendable desire to know something of the great industry with which they are associated, a desire which is shared by many others whose connexion with the industry is indirect." Certainly Mr. Kewley's book admirably fulfils such a purpose. It is not a technical treatise ; it is not a " popular " handbook, but a very judicious blend of the two, in which no phase of the subject escapes treatment, although necessarily restrictions of space have precluded in some instances more than a brief reference. Any inadequacy in this respect is largely overcome by references to original papers, or to other published works.

Mr. Kewley has divided his matter into nine parts, with several sections to each :—I.—Introductory (Terminology, History, Chemistry, Geology, and Theories of Origin) ; II.—Natural Gas : III.—Crude Petroleum ; IV.—Oils from Shale, Coal, Lignites, etc. ; V.—Natural Bitumens, etc. ; VI.—Mineral Waxes ; VII.—The Working-up of Crude Oils ; VIII.—The Characters and Applications of Petroleum Products ; IX.—Testing. It is impossible to consider in any detail these various parts, but certainly the sections on Natural Asphalts and Bitumens, and their applications for road-making, &c., are to be commended in view of the great development of the arterial road systems of the country and the rapidly extending use of these materials for road construction. The part on testing is covered by some eleven pages and detailed instructions are not attempted. References to the most suitable tests and useful comments on their value make it, however, quite sufficiently detailed for all except the analyst.

Here and there unforgivable errors have escaped correction in the proof ; thus in a table of fuel consumptions minimum " compression " per I.H.P. hour is given in lb. and pints ! Again, in dealing with coal-tar oils in Diesel engines, it is stated that as their ignition temperature is *lower*, pilot-jet ignition with petroleum oil is usual.

J. S. S. Brame.

MARKET REPORT

This Market Report is compiled from special information received by the Society from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid 40% tech. has advanced in price to an average of £20 per ton owing to the increased cost of acetate of lime. This was inevitable and the surprising feature is that it did not take place earlier. Imported parcels are in short supply but still continue to be offered.

There is not much demand for **Nitric Acid**, and the price ranges from £25 to £27 for 80° Tw.

Sulphuric Acid 94% arsenical remains unaltered at £6 10s. per ton.

Sulphate of Alumina has recently been imported in large quantities and foreign competition is very keen. The demand for **Ammonia Alkali** is quite up to the average and the position is firm. Makers have reduced contract prices for 1923 delivery by 5s. per ton.

White Arsenic continues to be very scarce at £65-£70 per ton.

A slight improvement is reported in the market for **Bleaching Powder.** Manufacturers' prices for contracts over the whole of 1923 have been reduced to £10 10s. per ton.

Calcium Chloride at £6 per ton carriage paid is meeting with keen competition from German imports at low prices. There is not much change to report in the position of **Salt Cake**, except in respect of export inquiry which, as usual at this period of the year, shows a falling off. The price is firm at £4 10s. per ton. The manufacturers have made a substantial reduction in the price of **Caustic Soda** for contracts over the whole of 1923, but the tone of the market just now is none too cheerful. **Soda Crystals** are valued at £5 10s. per ton carriage paid, **Sodium Bicarbonate** at £10 10s. per ton, and **Salammoniac** at £32 per ton, and **Sodium Acetate 97—98%** at £23 per ton. **Sodium Chlorate** is a very unsatisfactory market and is being imported at about 2½d. per lb. **Sodium Sulphide** prices show a downward tendency and home manufacturers are evidently making an effort to meet the very keen foreign competition. **Bisulphite of Lime** £7 per ton packages extra and returnable.

Sodium Bisulphite Powder 60—62% varies from £19 to £20 10s. per ton, according to quantity f.o.b. or f.o.r. London, 1 cwt. drums included.

Sodium Sulphite pea crystals £17 to £17 10s. per ton, 1 cwt. wooden kegs included. **Potassium Bichromate** 6¼d. per lb. d/d.

Sodium Nitrite £30 per ton 100% basis delivered.

WOOD DISTILLATION PRODUCTS

The demand for Wood Distillation products has very considerably improved and there is a ready market for most products, particularly Miscible Wood Naphtha which at the present time is exceptionally scarce owing to non-arrival of shipments from America. Consequently, the price is again up to an artificial level which will undoubtedly come back as soon as imports again arrive, and these are expected in the near future. There is also a large demand for Grey Acetate of Lime and inquiries are arriving regularly from the Continent. Manufacturers' prices are as follows :—

Acetate of Lime brown	£8 per ton delivered
Acetate of Lime Grey 80%	£14 10s. per ton d/d.
Acetate of Lime liquor	9d. per gallon 32° Tw. delivered.
Charcoal	£9 10s. to £10 per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw.
,, ,,	1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14—15° Tw
Wood Creosote	2s. 6d. ,, ,, Unrefined
Wood Naphtha, Miscible	7s. ,, ,, 60% O.P.
Wood Naphtha, Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£4 10s. per ton d/d.
Brown Sugar of Lead	£36 per ton.

TAR PRODUCTS

Amongst the products in this section **Acid Carbolic Crude 60's** is in good demand at the higher price of 2s. 5d.-2s. 6d. per gallon. **Acid Cresylic 97—99** varies from 2s. 1d. to 2s. 5d. per gallon, while **Acid Cresylic Pale 95%** is somewhat cheaper at 2s. to 2s. 2d., and **Acid Cresylic Dark** varies from 1s. 9d. to 2s. per gallon, with only a small demand. **Anthracene Oil, strained,** 8¼d. to 10d. per gallon, while **Anthracene Oil, unstrained,** can be bought for 7½d. per gallon. **Benzole, crude 65's** 1s. to 1s. 0½d. per gallon. **Benzole, Standard Motor,** 1s. 8d. to 1s. 9d. per gallon, **Benzole, Pure,** 2s. to 2s. 6d. per gallon, according to quality and district.

Toluole 90%, 1s. 10d. per gallon. **Toluole Pure,** 2s. to 2s. 6d. **Xylol,** 3s. **Creosote, Cresylic, 20—24%,** 10d. to 10½d. **Creosote, Middle Oil,** 7½d., **Creosote, Heavy,** 7½d., **Creosote, Standard Specification,** 6¾d. to 8¼d. per gallon, according to district. This market is very firm. **Naphtha, crude** 10d. **Naphtha, Solvent, 90—160,** 1s. 7½d. to 1s. 9d.

Naphtha Solvent, 90—190, 1s. 7d. **Naphthalene, Crude,** drained creosote salts is in good demand, but prices vary considerably from £5 to £7 in different districts. **Naphthalene Crude** Whizzed or Hot Pressed varies from £7 to £15 per ton according to quality and district. **Naphthalene Crystals,** £16 per ton, **Naphthalene, Flaked,** £14 10s. per ton, **Pitch, Medium Soft** again very firm at 120s. to 132s. 6d., according to district. **Pyridine, 90—140,** very firm at 10s. to 12s. 6d. per gallon, **Pyridine, Heavy,** 8s. 6d. to 9s. 6d. per gallon.

INTERMEDIATES AND DYES

The New Year has opened well for business in Dye-stuffs and orders are coming in very freely. Prices of the leading intermediates are as follows, carriage paid and packages included unless otherwise stated :—

Acid H.	5s. 3d. per lb. 100% basis.
Acid Naphthionic	2s. 8d. lb. 100% basis.
Acid Neville & Winther	6s. lb. 100% basis.
Acid Sulphanilic	1s. 6d. lb. 100% basis.
Aniline Oil	11½d. drums extra.
Aniline Salts	11½d. per lb.
Benzidine Base	6s. 6d. 100% basis.
Dinitrobenzene	1s. 3d. lb.
Diphenylamine	4s. 1d. lb.
α-Naphthol	2s. 9d. lb.
β-Naphthol	1s. 2d. lb.
α-Naphthylamine	1s. 7d. lb.
β-Naphthylamine	4s. 6d. lb.
p-Nitraniline	3s. lb.
Nitrobenzene	8d. lb., drums extra.
Nitronaphthalene	1s. lb.
Naphthionate Soda	2s. 8½d. lb. 100% basis.
Diethylaniline	4s. 6d. lb., packages extra returnable.
Metanitraniline	5s. 6d. lb.
Para Toluidine	5s. lb.
Para Phenylene Diamine	12s. lb. 100%
Meta Phenylene Diamine	5s. 6d. lb.
Meta Toluylene Diamine	5s. lb.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The market has been temporarily quiet during the stocktaking and holiday period, but a renewed demand is expected in the near future. Prices generally tend to be harder owing largely to the advancing prices of German products. Current quotations are as follows:—

Acid Acetic 80%	£43 per ton.
Acid Acetyl Salicylic	3s. lb. for best makes. Higher prices are expected in the future.
Acid Benzoic	2s. lb. on a steady market
Acid Citric	1s. 8½d.-1s. 9d. less 5% market firm.
Acid Salicylic	1s. 4d. lb.
Acid Tannic	3s. 3d. lb.
Acid Tartaric	1s. 2½d. to 1s. 3d., market firm and fair demand.
Amidol	9s. per lb.
Acetanilide	1s. 4d. lb. stationary.
Amidopyrin	14s. lb.
Barbitone	12s. 6d. lb.
Benzaldehyde free from Chlorine	3s. 3d.
Chloral Hydrate	4s. lb.
Hexamine	3s. 3d. lb. for good free crystals. Market very firm.
Homatropine Hydrobromide	30s. per oz.
Menthol	40s. 6d. less 2½% original cases. Smaller quantities 41s. 6d. per lb. net.
Methyl Salicylate	2s. lb. in steady demand.
Paraldehyde	1s. 6d. to 1s. 9d. per lb.
Phenacetin	5s. lb. firmer.
Phenolphthalein	5s. 3d. lb. with little available on the spot.
Potassium Bitartrate, 99—100% (Cream of Tartar)	100s. to 103s., less 2½% per cwt. Market firm with good demand and prices well maintained.
Potassium Permanganate	8d. to 8½d. lb., with more inquiry.
Sodium Benzoate	2s. lb. for good make.
Sodium Hyposulphite, Photographic	£15 to £17 per ton according to quantity, delivery buyer's station.
Sodium Potassium Tartrate (Rochelle Salt)	85s. per cwt. net.
Sodium Salicylate	1s. 11d. lb. for powder unchanged.
,,	2s. 1d. lb. for crystal.
Sodium Sulphite, anhydrous	£27 10s. to £28 10s. per ton according to quantity, f.o.r. London, drums included.
Sulphonal	13s. 6d. lb., present value on a weak market.

Thymol	17s. to 19s. lb. according to quality.
Atropine Sulphate	12s. 6d. oz. is the present value, but higher prices are anticipated in the near future.
Pilocarpine Nitrate	22s. 6d. oz.

PERFUMERY CHEMICALS

There are very few changes to record this week among Perfumery Chemicals, business in which has been rather quiet. Current prices are as follows:—

Amyl Acetate	2s. 3d.
Amyl Butyrate	8s.
Amyl Salicylate	3s. 3d.
Anethol, melting point 21—22° C.	4s. 6d.
Benzyl Acetate from chlorine-free Benzyl Alcohol	3s. 3d.
Benzyl Alcohol free from chlorine	3s. 3d.
Benzaldehyde free from chlorine	3s. 3d.
Benzyl Benzoate 19·5° C.	3s. 3d.
Cinnamic Aldehyde, 98—100% Natural	14s. 9d.
Citronellol	22s. 6d.
Citral, 100%	10s. 6d.
Ethyl Phthalate	4s. 6d.
Eugenol, 100%	10s. 6d.
Geraniol (from Palmarosa)	32s. 6d.
Geraniol	5s. 6d. to 12s. 6d.
Iso Eugenol	16s.
Linalol ex Bois de Rose	21s.
Linalyl Acetate	22s. 6d.
Methyl Benzoate	8s. 6d.
Phenyl Ethyl Acetate	10s.
Phenyl Ethyl Alcohol	17s. 6d.
Rhodinol	52s. 6d.
Terpineol	2s. 10½d.
Vanillin, 100%	23s. 6d.

ESSENTIAL OILS

Among Essential Oils, **Bourbon Geranium, Clove** and **Japanese Peppermint** are all lower in price this week, while **Cananga Oil** is dearer at 9s. and **Citronella** continues its firm tendency.

Anise Oil, Red Ship Brand	2s. 1½d.
Bourbon Geranium Oil	23s. for shipment.
Cananga Oil, Java	9s. firm.
Cinnamon Oil, Leaf	4¼d. per oz.
Cassia Oil, 80—85%	8s. 7½d.
Citronella Oil, Java, 85—90%	3s. 6d.
Citronella Oil, Ceylon	2s. 6d.
Clove Oil, English, 90—92%	7s. 9d.
Eucalyptus Oil, 70—75%	1s. 10d.
Lavender Oil, Mont Blanc 38—40%	14s. 6d.
Lemon Oil, spot	2s. 10d., new crop for shipment, 2s. 7d.
Orange Oil, sweet spot	9s. 6d., new crop for shipment 8s. 3d.
Otto of Rose Oil, Anatolian	24s.
Otto of Rose Oil, Bulgarian	28s.
Peppermint Oil—	
English Mitcham	80s.
Wayne County	13s. 6d.
Japanese	7s. 6d.

TRADE NOTES

Papua in 1920-21

The annual report of the Lieut.-Governor of Papua states that the year 1920-21 was a difficult one, as prices of copra, rubber and copper fell below the cost of production. The total value of the exports decreased by nearly £100,000 to £172,672, shipments of rubber falling by 22 to 220 tons and of copra by 1096 t. to 2984 t.; other exports were: gold 5984 oz.; osmiridium 208 oz.; copper ore 255 t. The output of gold depends on the development of the Misima mine as the mining of alluvial gold has practically ceased. Shipments of copper will increase greatly if the Laloki mine proves successful. Imports rose in value by £62,000 to £484,770, largely owing, not to industrial activity, but to Government purchases.—*Ind.-Austr., Nov.* 16, 1922.)

Chemicals at the British Empire Exhibition, 1924

Arrangements have now been completed for organising the Chemicals Section of the British Empire Exhibition. The section will be on a very large scale, 25,000 sq. ft. of space having been alloted to it, and the organisation has been entrusted to a Committee of the Association of British Chemical Manufacturers, assisted by representatives of the Society of Chemical Industry and allied bodies. There is every indication that the exhibits will be fully worthy of the importance of the chemical industry. In fact, it may be said that this section stands next to the engineering, electrical, and transport sections of the Exhibition in its demand for space. A large number of the big manufacturing firms of the Kingdom have already applied. Part of the Section will probably be devoted to perfumery; and suggestions have also been received from firms desiring to show the whole process of soap making by modern machinery, with soaps of all descriptions, dentrifice and other toilet preparations. The secretary of the Section is Mr. W. J. U. Woolcock, of 166, Piccadilly.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, JANUARY 19, 1923 No. 3

EDITORIAL

SIR ARCHIBALD GEIKIE a few years ago described the disintegrating effect of frost and rain on the surface of the earth and how the valleys are being continually cut deeper and deeper by these agencies. The process is slow but perceptible, and he explained that he himself found the hills he climbed in Scotland both steeper and higher than he did five-and-twenty years previously. The phenomenon is apparent in many other branches of knowledge. The small type, in which our Transactions, our Reports of Sectional Meetings, and our News from other Societies, have appeared for some years, is gradually becoming less distinct, the fine edges are occasionally blurred and it is less easy to read than it was formerly. We are therefore proposing to substitute a slightly larger type for all these, and we hope that our readers will approve of the change. Sometimes the older readers amongst us become the more conservative and the less inclined to endure a change from that appearance to which they are accustomed, but we trust that these also will acquiesce in the new departure even if they do not really approve of it.

* * *

The Society of Chemical Industry is more than a society for the diffusion of useful knowledge; it is a powerful stimulus to chemists all over the world to realise themselves, and help others to realise, how varied and how important are the points which Chemistry and Industry have in common. The Society aims at doing even more; it makes an honest endeavour to act as a bond between all those countries whose civilisation is so advanced that the chemist is regarded as an essential member of the community. It cannot be doubted that the Society has done much to promote a cordial feeling between French and British chemists, and it is a source of special pride to us that we maintain steady lines of communication with our kinsmen across the seas. We ought, indeed, to be grateful to the Canadian, American and Australian Sections who form so considerable a proportion of our members. One form our gratitude will take will be a readiness to accept news from them, another will be a zeal to supply them with an account of what excites interest in chemical circles in various parts of Europe. We are ambitious to acquire these items of information, to pick up from all quarters the newest ideas and discoveries, confirm the tidings as they roll and spread the truth from pole to pole. The correspondence we print between our President and our Ex-President has a special significance for us. Our recent Annual Meeting in Canada, and the recent visit of our Canadian President to us in Great Britain have enlightened us; some of us may have in a couple of years' time an exceptional opportunity of visiting our chemical friends in America, and we are quite sure that between now and then several of them will visit us. After all it is almost true to say that it is chemistry—and what chemistry can do—that stands as a barrier between us and a relapse into chaos and barbarism. Our duty is plain, and we English-speaking chemists must shoulder a large part of the burden.

* * *

Was it not Lord Rosebery who defined the two occasions when men make speeches, the first when they have something to say, the second when they have to say something? The same statement may be made of writing. We could—if professional etiquette did not forbid—mention several men of note, any one of whom may, at short notice, in virtue's cause once more exert his rage, his satire point and animate our page. The pursuit of knowledge and the *cacoethes scribendi* are Mendelian traits liable to appear in unsuspected individuals, and in general once they appear they continue so long as the organism has any unsatisfied energy. It seems to us that the desire for research is an extreme form of the desire to solve a puzzle, inherent in so many of us. Probably three-quarters of the population lose this desire in early youth, of the remainder, some love to pursue to the earliest period the intricacies of their pedigree and derive keen satisfaction from the discovery of the marriage certificate of some great-uncle in whom they have no interest; but this discovery fills a place in the jig-saw puzzle, and they are satisfied. The man with this desire for pursuit will take up an inquiry into solutions and go on, thinking only of the difficulties which appear, and how they can be made to fit in with the jarring pieces; finally he sees how these difficulties affect the study of valency and substitution and gives us a result such as the one we print this week. The suggestions are full of promise, but those who think as we do are not much concerned whether Prof. Lowry's views are correct or not: what is of supreme importance is that he shall continue his interest in such problems and continue to explore "nature for principle or cause, keenly with all the cunning pleasure and instinct of a hunter." In this way, and in this way only, is knowledge increased.

* * *

Since the Gas Regulation Act of 1920 came into force, the services rendered by the gas industry to the public have been the subject of much discussion. Complaints about the application of the admittedly logical system, introduced under the Act, of charging for gas by its thermal value instead of by volume have been many, and the Board of Trade has been induced to refer the matter for inquiry to a Committee, now in session. In addition, the decision of a previous Board of Trade Committee not to recommend any limitation of the proportion of carbon monoxide allowable in gas has been strongly criticised, in view of the danger due to the presence of this colourless, odourless and extremely poisonous constituent. Professor W. A. Bone, writing in *The Times* of January 12, points to the heavy death-roll due to gas-poisoning during the past year as "a sufficient comment upon the folly of that decision," and urges that the question should be re-examined by a Committee composed of disinterested and scientifically competent persons. The same question has also been faced in the United States, but apparently without reference to a committee, for the U.S. Chemical Warfare Service has, it is reported, obtained encouraging results in experiments on the admixture of "sneezing" gas with illuminating gas as a means of detecting an escape of the latter, the sternutatory ingredient being destroyed when the gas is burned. In this country, however, such technical matters have to be considered by committees which are so constituted that distinguished men of science have to plead for the appointment of at least some members with a scientific training. Yet there is no lack of able chemists in this country. The moral is obviously that Chemistry and its practitioners have not yet attained importance in the public eye and that the lesson "unity is strength" has still to be learned if chemists are to be consulted on questions in which their science as well as the public welfare are so vitally concerned.

THE CANADIAN SECTIONS OF THE SOCIETY OF CHEMICAL INDUSTRY

The following letter was recently sent by the President to the Chairman and Executive Committee of the Canadian Sections:—

Gentlemen,—I conceive it to be one of the main duties of the President during his period of office to visit as many as possible of the Sections of the Society, both for the purpose of interchanging ideas and realising local conditions and of ventilating, more or less publicly, some of the aims, difficulties, and achievements of the chemist. Unfortunately, distance—both in space and time—will prevent me from visiting the very active Sections in Canada, and I am therefore constrained to send this letter as a message of good will, testifying to the great interest which the Council at home has in the progress of Chemistry in the Dominion.

The real aim of the Society is the encouragement of the progress of Chemistry in Industry, and, believing as we must that chemical science is the foundation of all industry, of every manufacturing process and of every-day life, we feel sure that the trained chemist must play an ever-increasing part in the development of the natural resources, and indeed of civilisation itself, in your country.

Untrammelled to a large extent by the traditions, restrictions and mistakes of the past which play so large a part in the daily life in the old country, you have a unique opportunity to win for the chemist an all-prominent position and influence in the development of the Canadian nation. To achieve this, the chemist must so shape his activities as to be regarded above all as a shrewd counsellor and a constructive adventurer, in addition to his more generally understood *rôle* as an analyst and guardian of the public services.

Important as is the dual position of Chemistry as the detective and policeman among the Sciences, it is far more necessary that to-day, in what is perforce a utilitarian world, it should establish its real position as *the* constructive Science affording the foundation of theory and experiment on which engineering and physical science can achieve their conquests of nature.

If these objects are to be attained the chemist must be a man of broad and practical outlook, enthused with the noblest ideals and with a wide knowledge of his subject. We must aim at the highest standard of professional etiquette within our ranks and avoid the prostitution of our status by the unqualified. Above all, we must realise to the full the advantages of co-operation, believing that it is only by a united effort that the profession of Chemistry can attain to the goal of its desires.

If the ideals indicated in the foregoing are high they are all the more worthy of achievement, and we feel that our Society has done—

and can continue to do—the pioneer work towards their attainment.

The temptation to form a purely Canadian organisation must be often before you, but you will allow us to urge that the willing help without the interference, and the mature experience of the larger body at home is far too great a weapon in your armoury to be lightly abandoned.

During the last eighteen months the Society has had the advantage both of paying an official visit to Canada and of having as its President Dr. Ruttan, an eminent Canadian, who adds great personal charm to his shrewd character as a man of affairs. We feel, in consequence, that we know you more intimately than at any previous time, and that the link between us to-day is based on personal attachment as well as on loyalty to the Motherland. To-day, when it falls to the lot of the Anglo-Saxon nations to bring order out of the world's chaos and start civilisation once more in the path of peace, the opportunity for the individual chemist and for our Society is a great one and we must prove ourselves worthy of it.

I desire to assure you that the Council takes a very real and deep interest in the welfare of the Society in Canada, and that it appreciates very highly the efforts that you and our members in the Dominion have made to consolidate the work of the Sections and to develop their potentialities.

I need hardly say that we shall, at all times, be glad to render you such support as we can in your valuable endeavours. With very kind regards.—Yours sincerely,

E. F. Armstrong,
President.

The following reply was received :—

My dear Armstrong,—I received your letter conveying a greeting to the different Sections of the Society of Chemical Industry in Canada. I have had this letter manifolded and a copy sent to the Secretary of each Section to be read at the first meeting. I had the pleasure of reading your letter to the Montreal Section yesterday, which was the day on which it arrived.

I must congratulate you on the success which has attended your efforts to improve the Journal, and I also congratulate the Society on having a President who is able and willing to give so much time and attention to his duties.

I hope it is not impossible that you should make a flying visit to America. We should all be very much delighted to see you in Montreal. With kind regards, I am,

Sincerely yours,
R. F. Ruttan,
Chairman of Executive.

THE UNIQUENESS OF HYDROGEN

By PROF. T. M. LOWRY, F.R.S.

MORE than one author has recently expended his energies and tested the patience of his readers by discussing the question as to whether hydrogen should be regarded as a lower homologue of the univalent alkali metals or of the univalent halogens. This problem, which may be compared with the still older problem of whether liquid hydrogen would prove to be a metal or a paraffin, was of some interest 50 years ago, when the simple theory of octaves dominated the periodic classification of the elements. It is, however, curious that it should still survive at a time when the existence of periods of 2, 8, 18 and 32 elements has been so clearly established. In these circumstances the columns of Mendeleef's table have become a purely conventional framework, by means of which it is possible to economise space, and to diminish the effort of memory, as compared with a table in which the 32 elements of the longest series are set out on one horizontal line. This conventional form of the periodic table appears, however, to hold a remarkably firm place in the mentality of chemists in view of the fact that problems such as the one suggested above are still considered worthy of consideration.

A much clearer view of the relationship between hydrogen and the other univalent elements is obtained by means of the electronic theory of valency as enunciated by Lewis. To Lewis belongs the merit of providing for the first time a clear picture (together with a plausible explanation) of two distinct types of chemical affinity, the existence of which had been recognised in a confused way during a period of not much less than a century. Throughout this period inorganic chemists, following Berzelius, had postulated the existence of a polar type of chemical affinity, whereby *unlike* elements were held together by polar forces which were probably electrical in character. Organic chemists, on the other hand, in view of the remarkable experiments of Dumas on the substitution of "electro-negative" chlorine for "electro-positive" hydrogen, had postulated a non-polar type of affinity, whereby carbon could be linked indifferently either to hydrogen or to chlorine. The natural corollary to this facile substitution was that *like* elements could be linked together, *e.g.*, hydrogen to hydrogen, or chlorine to chlorine, by a non-polar valency passing symmetrically between two identically similar atoms of the same element. Chemists were, however, very slow to admit that chemical affinity could be of two types; and whilst the majority of organic chemists followed Kekulé in representing *all* the bonds between the atoms as non-polar, there were others such as Fry* who assumed that *all* the valencies were of the polar type suggested by Thomson and Ramsay, namely, a Faraday tube of force passing from a positive charge in one atom to a negative charge in another.

---

* "The Electronic Conception of Valency."

According to the octet theory of Lewis, the elements owe their valency to the powerful but mysterious force which urges them to build up groups of 2, 8, 18 or 32 electrons. This force, which may be merely the effect of a second term in the inverse square law of electrostatic attraction, is evidently identical with what has been described during many generations as "chemical affinity," since it is this which determines chemical combination between atoms. The building up of the stable groups of electrons, which in the case of the elements from carbon to calcium are usually octets, can be done in two principal ways (i.) *by transferring electrons from one atom to another*, *e.g.*, from an atom which holds too many electrons to one which holds too few; or (ii.) *by sharing electrons between adjacent atoms*, so that two atoms which are both deficient in electrons may achieve a condition of completeness which neither could reach alone. In the former case the completion of the groups leaves the atoms oppositely charged, but held together by electrostatic forces, giving rise to a typical polar valency, which Langmuir distinguishes as electrovalence. In the latter case, since electrons may be shared by two identical atoms, the valency may be completely symmetrical and non-polar: this type of valency Langmuir distinguishes as covalence. This sharp distinction between two types of valency receives support from crystallographic data, since it appears that the distance between two atoms is less when they are held by covalency than when held by electrovalency.

In the majority of cases these two types of valency can be distinguished quite sharply, as in the typical cases of $\overset{+}{\mathrm{Na}}\,\overset{-}{\mathrm{Cl}}$ and Cl–Cl. In the case of the halogens, a question may indeed arise as to whether the dissociation of the molecule (*e.g.*, of chlorine in forming $\mathrm{Cl{\cdot}CH_2{\cdot}CH_2{\cdot}Cl}$ from $\mathrm{C_2H_4}$ and $\mathrm{Cl_2}$) takes place symmetrically, giving rise to two neutral atoms each carrying a septet of electrons as in (i) below, or into one atom carrying a complete octet (and therefore negatively charged) and a second carrying only a sextet of electrons (and therefore positively charged) as shown in (ii) below, where the symbols in heavy type represent the kernels of the atoms, *i.e.*, the atom minus its valency electrons.

(i) $:\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{Cl}}}:\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{Cl}}}: \rightleftarrows :\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{Cl}}}\cdot + \cdot\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{Cl}}}:$ or $\mathrm{Cl_2} \rightleftarrows \mathrm{Cl} + \mathrm{Cl}$

(ii) $:\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{Cl}}}:\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{Cl}}}: \rightleftarrows :\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{Cl}}}: + \ \overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{Cl}}}:$ or $\mathrm{Cl_2} \rightleftarrows \overset{-}{\mathrm{Cl}} + \overset{+}{\mathrm{Cl}}$.

But, until the division of the molecule actually takes place, there is no reason why the symmetry of the molecule should not persist, and with it the completely non-polar character of the bond between the atoms. It is, however, just here that the uniqueness of hydrogen becomes apparent, since the two types of valency cannot in this element be distinguished in this simple and easy way. Thus, in the case of hydrogen chloride, the electronic formula of the molecule is $:\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{Cl}}}:\mathbf{H}:$ the electronic formula of the ionised acid is $:\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{Cl}}}:+\mathbf{H}$, where the hydrogen ion may be regarded provisionally as a mere naked nucleus—a single proton carrying no electron either in the nucleus or outside. When the hydrogen ion is remote from the chlorine ion the forces between them are evidently electrostatic, and polar in character, and the affinity between them is clearly due to electrovalency. But when the two atoms are close together, they may be regarded as sharing a pair of electrons and therefore united by a covalency. How can these two states be distinguished, and when does one pass into the other? This problem did not arise in other cases, since any other element attached to chlorine would either carry sufficient electrons to make two octets and so develop an electrovalency, or would not carry a sufficient number, and therefore be reduced to sharing electrons and thus give rise to a covalency. The unique behaviour of hydrogen is due to the fact that a stable configuration can be obtained either with no electrons, as in the hydrogen ion, or with two electrons, as in the hydrogen molecule **H:H**. In the case of chlorine the removal of two electrons has the effect of converting the octet—not into another stable configuration—but into a highly unsaturated sextet.

I am indebted to Sir William Bragg for a suggestion that appears to provide the necessary test for distinguishing between hydrogen nuclei acting as ions and hydrogen nuclei acting like organic radicals. He suggests that the difference depends on the directional (or anisotropic) character of covalency as contrasted with the approximately uniform distribution (or isotropy) of the field of force round an ion. A test case is that of water. The molecule of monohydrol is $\mathbf{H}:\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{O}}}:\mathbf{H}$; but the type of valency by which the atoms are held together is not immediately clear. Bragg suggests that if we were really dealing with ions of hydrogen and ions of oxygen held together by electrostatic forces,

$$\mathbf{H}+:\overset{\cdot\cdot}{\underset{\cdot\cdot}{\mathbf{O}}}:+\mathbf{H},\ \text{or}\ \overset{+}{\mathbf{H}}+\overset{--}{\mathrm{O}}+\overset{+}{\mathbf{H}},$$

the immediate result would be that the crystals would assume a cubic symmetry, in which the ions would be arranged in precisely the same way as in

fluorspar, $\overset{-}{\mathrm{F}}+\overset{++}{\mathrm{Ca}}+\overset{-}{\mathrm{F}}$, or in
silver sulphide $\overset{+}{\mathrm{Ag}}+\overset{--}{\mathrm{S}}+\overset{+}{\mathrm{Ag}}$.

In all crystals of this type the ions, although relatively bulky, are closely-packed, whereas the structure of ice is of an open cage-like type into which many more atoms could be packed if they were free to slide about on one another like smooth spheres. In this respect ice agrees with diamond, and still more closely with the crystals of organic compounds, where the density is even less and the structure even more open than in the diamond. This low density and open structure are only rendered possible by the fact that the forces of covalency are limited to certain directions round the atom, along which (and not elsewhere) combination with other atoms must take place. The open structure of ice is therefore clear evidence that the hydrogen atoms are linked to oxygen by covalency, and this conclusion is in harmony with the very low conductivity of pure water as compared with fused salt.

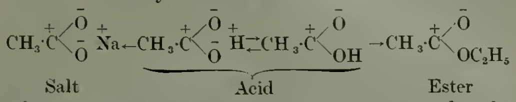
From the point of view of the octet theory, Bragg's distinction between the two types of union of hydrogen with other atoms may be expressed by saying that in the case of a hydrogen ion the free nucleus can attach itself to any one of the 12 edges of the cube, if that is the real form of the octet, or to any one of the 4 corners of the tetrahedron, if the 8 electrons of the octet are disposed as four symmetrically-arranged duplets; but in the case of a hydrogen radical the nucleus is specifically attached to one duplet only of the four which make up the octet. Mobility, and freedom to wander from bond to bond on an atom or molecule, are therefore the distinguishing features of an ion as contrasted with a radical; but in the case of hydrogen these may be developed gradually, as a result of the progressive change of one type of valency into the other.

The unique character of hydrogen is seen most clearly in the wide contrast which exists between the acids and all other classes of compounds, except perhaps the bases, which may be regarded provisionally as mere neutralisers of acids. In the case of a chlorine molecule the non-polar character of the bond is probably retained until dissociation actually takes place, when it may (or may not) dissociate with ions; if it does, the type of valency alters quite abruptly on dissociation. On the other hand, in the case of common salt, the neutral molecules are probably only pairs of ions held together by electrostatic attraction and the force between them is an electrovalency both before and after ionisation. But in the case of hydrogen there may be a progressive weakening of the hold of the molecule on the nucleus, which will convert the compound quite gradually from a neutral substance to a weak and then to a strong acid, as a larger and larger proportion of hydrogen atoms becomes mobile, as in the series

$$CH_3{\cdot}CH_3 \rightarrow CH_3{\cdot}CH_2{\cdot}OH \rightarrow CH_3{\cdot}CO{\cdot}OH \rightarrow CCl_3{\cdot}CO{\cdot}OH.$$

We therefore have weak acids and strong acids, as well as strong and weak bases, but not strong and weak salts where the bonds are always electrovalencies, nor strong and weak methyl derivatives where the bonds are always covalencies.

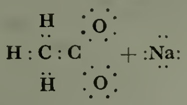
In the case of the carboxylic acids, Hantzsch has carried the idea of mobility so far as to assume that the acid can exist in a form in which the hydrogen ion is attracted equally by *both* oxygen atoms, as in the formula $CH_3{\cdot}C\left\langle\begin{matrix}O\\O\end{matrix}\right\}H$. Hantzsch's theory may be expressed in terms of the electronic theory of valency as follows :—



In the salt, the sodium ion is supposed to be equally attached to both oxygen atoms, but in the esters the alkyl radical is attached specifically to one. In the acid itself Hantzsch postulates the existence of both types, a true acid from which the salts are derived, and a pseudo-acid from which the esters are derived; but it is by no means clear that these could not also be regarded as the ionised and un-ionised forms of the acid. The absence of the ketonic property of unsaturation in fatty acids is easily understood if unsaturation is identified with electrical polarity, since in the ionised acid and its ionised salts the maximum of unsaturation is between the two ions, but gives rise only to an interchange of radicals, *e.g.*, between $CH_3{\cdot}CO{\cdot}\overset{-}{O}\overset{+}{H}$ and $\overset{+}{H}\overset{-}{C}N$ instead of to addition-compounds as in the interaction of hydrogen cyanide with acetone

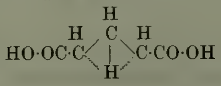
$$\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\overset{+}{C}-\overset{-}{O} + \overset{+}{H}\overset{-}{C}N \rightarrow \begin{matrix}CH_3\\CH_3\end{matrix}\!\!>C<\!\!\begin{matrix}OH\\CN\end{matrix}$$

In the formulæ set out above, the carbon atom which is shown as positively charged is assumed to carry a sextet, the complete electronic formula of sodium acetate being

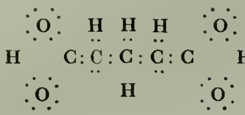


In this formula the total number of electrons will be found to be correct if two K-electrons (in addition to the L-electrons shown in the formula) are assigned to the kernel of each carbon and oxygen atom.

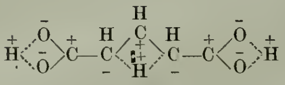
A similar formula may be given to glutaconic acid which Thorpe writes as



The corresponding electronic formula for this acid is



or



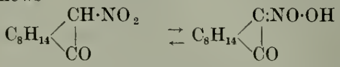
where again the kernel of each positively-charged carbon atom is surrounded by a sextet instead of an octet. In this formula the two acidic hydrogen atoms are shown as occupying a symmetrical position between the two negatively-charged oxygen atoms of the carboxyl-group, to which they are attracted by electrostatic forces—the "partial valencies" of Thiele. The third mobile hydrogen, to which glutaconic acid owes its special properties is, however, seen to occupy a precisely similar position between two negatively charged –CH– groups, so that there is a complete analogy between the central group of the glutaconic acids  and the carboxyl-group of formic acid . Ethyl acetoacetate contains the intermediate grouping . A similar group may perhaps exist in the amidines, *e.g.*, .

It is a remarkable fact that strong acidity is apparently developed only in mixtures and never in pure compounds. Even hydrogen chloride only becomes an acid when mixed with water. This can be explained by the extreme reluctance of a hydrogen nucleus to lead an isolated existence, although it is quite willing to attach itself to any octet that is not too unfriendly, or too fully occupied by other atoms to leave room for an additional nucleus. The effect of mixing hydrogen chloride with water is probably to provide an acceptor for the hydrogen nucleus so that the ionisation of the acid only involves the transfer of a proton from one octet to another.

$$:\underset{\cdot\cdot}{\overset{\cdot\cdot}{Cl}}:H + H:\underset{\cdot\cdot}{\overset{\cdot\cdot}{O}}:H \rightleftarrows :\underset{\cdot\cdot}{\overset{\cdot\cdot}{Cl}}: + H:\underset{\cdot\cdot}{\overset{\overset{H}{\cdot\cdot}}{O}}:H$$

$$\text{or} \quad Cl\,H + H_2O \rightleftarrows \overset{-}{Cl} + \overset{+}{O}H_3$$

The ionised acid is then really an ionised oxonium salt. In very much the same way nitrocamphor and the two isomeric forms of ethyl acetoacetate, which in the presence of a trace of alkali undergo isomeric change as follows



$$CH_3{\cdot}CO{\cdot}CH_2{\cdot}CO{\cdot}OC_2H_5 \rightleftarrows CH_3{\cdot}C(OH):CH{\cdot}CO{\cdot}OC_2H_5$$

are stable compounds when carefully purified. The mobile hydrogen atom acquires mobility only in the presence of a base, or other suitable catalyst, and unless this is present isomeric change does not take place.

It is commonly suggested that the alkalis or bases are as unique as the acids, and that the hydroxyl ion occupies just as peculiar a position as the hydrogen ion. This, however, is a narrow view, based on the fact that most of our chemical work is done in presence of water, if not actually in aqueous solutions. The real function of a base is that of an acceptor of hydrogen nuclei, and one of the simplest cases of neutralisation is the acceptance of a hydrogen ion by a molecule of ammonia, $NH_3+\overset{+}{H}\rightleftarrows\overset{+}{N}H_4$. If the base is sufficiently strong it may not merely accept the free hydrogen nuclei which have been driven away from the molecules of an acid, but it may even steal them from compounds in which they are only weakly held, *e.g.*, from water, as in the action $NH_3+HOH\rightleftarrows\overset{+}{N}H_4+\overset{-}{O}H$. In this case the strength of the base is manifested by the liberation of hydroxyl ions, and can be measured by the proportion of these ions set free by each equivalent of the base. The hydroxyl ion is itself a strong base, since it is capable of accepting and retaining a very large proportion of the equivalent quantity of hydrogen ions. The combination of hydrogen with hydroxyl is, however, almost confined to aqueous solutions, whereas neutralisation by acceptance of a hydrogen nucleus may occur in any solvent in which hydrogen nuclei can be produced. In the same way the most powerful catalyst for the isomeric change of nitro-camphor is not a hydroxide, but a nitrogenous base, such as piperidine dissolved in benzene. This appears to set up isomeric change by providing an acceptor for the hydrogen nucleus, which can thus acquire a mobility which enables it to leave the nitro-camphor and return to a different position in the molecule.

SUMMARY

1. It is suggested that hydrogen is unique amongst the elements in that it is sometimes difficult to determine whether the bond by which it is attached to another atom is a covalency or an electrovalency.

2. In the case of crystals, a clear distinction can be made in view of the fact that ions held

together by electrovalency give rise to close-packed crystals, whilst molecules held together by covalencies give rise to open structures of low density. Ice consists, therefore, of molecules and not of ions.

3. The essential difference between a hydrogen ion and a hydrogen radical is that the former possesses mobility, whilst the latter is attached not merely to a particular atom but to a particular region in the structure of the atom, *e.g.*, by sharing one particular pair of electrons. This mobility can, however, be developed gradually, *e.g.*, on passing from a very weak to a very strong acid.

4. The mobile hydrogen atom of glutaconic acid bears the same relationship to two negatively-charged –CH– groups as the acidic hydrogen of a carboxylic acid bears to the two negatively-charged oxygen atoms of the carboxyl group. In ethyl acetoacetate the mobile hydrogen wanders between one negatively-charged oxgyen atom and one negatively-charged –CH– group.

5. A base is best described as an acceptor of hydrogen nuclei. Even in the case of strong acids the addition of water, acting as an acceptor, is needed in order to develop acidity. A basic acceptor is also needed to promote the migration of a hydrogen nucleus in nitrocamphor and in the two forms of ethyl acetoacetate.

LEGISLATIVE AND DEPARTMENTAL INTERFERENCE WITH INDUSTRY AND THE COMMON WEAL

(*Continued*)

By PROF. H. E. ARMSTRONG, F.R.S.

Mr. Klein and I brought the subject up to date in a communication to the Royal Society of Arts in July, 1921. We have there given an historical account and specially drawn attention to a new danger to industry, arising from the creation of an International Labour Office at Geneva and the holding of International Labour Conferences under regulations laid down in the Versailles Treaty of Peace.

Our first paper had reference to proceedings before one of the two Home Office Departmental Committees, appointed in 1911, to inquire into the dangers supposed to be attendant on the use of lead compounds in paints. The reports of these Committees were published separately in 1915 and 1920. Both agreed in practically prohibiting the use of lead paints. The Committees were not expert bodies—as we have said elsewhere, " not a single member was versed in the use of scientific method." Their verdict was a foregone conclusion and probably that they were appointed to give. It should be mentioned also that no mere humanitarian considerations have been in operation throughout the struggle : Belgian and French interests in the Zinc White Trade have also played an important part. Such is life.

The matter came before the first International Labour Conference, held at Washington, U.S.A., in November, 1919. It was recommended that " the prohibition of the use of White Lead in painting should be placed upon the Agenda of the next Conference."

In preparation for the Conference at Geneva, last year, the International Labour Office, at Geneva, prepared and issued not long in advance of the meeting, a Red Book which has the distinction of being probably the most inaccurate, biased and unfair statement ever made in preparation for the discussion of a serious subject. If the decisions of International Conferences are ever to have binding force, there must be an honest endeavour to arrive at truth. So strong was the expression of opinion, that the Director thought himself impelled to come forward in palliation of the work of his subordinate : instead of regretting the issue of such a document, he defended it and even claimed that it was the duty of the Office to take sides. We know, therefore, what to expect from Geneva and from such Conferences.

Our English attitude towards the matter has been altogether astounding. Immediately before the Geneva Conference, the Home Secretary appointed a new (third) Committee, now sitting, to examine reports, which his Office had received, throwing doubt on the conclusions of the two Committees appointed in 1911. I may anticipate, and say, that the hope Mr. Klein and I expressed in our Society of Arts paper, " that persons competent to understand the technical issues would be appointed," has been fulfilled—but at what cost of protest ?

What had really happened was, that the Office of Works—which, under pressure from the Home Office, had abandoned the use of White Lead Paint—had mutinied and returned to lead. Unknown to themselves, two distinguished architects had made a delightful comparative experiment with Buckingham Palace. The Office of Works had painted the section in their charge with leadless paint ; Sir Aston Webb had used genuine White Lead on his part. The leadless paint flaked off, whilst White Lead stuck hard.

Although this was known, the two British Government delegates to the Conference were instructed to take no part in the Lead debate—perhaps this was not a disadvantage, as neither had knowledge nor feeling on the subject. Strange to say, however, Great Britain accepted a place on the Committee, a Scientific Advisor on the subject to our Government delegates was appointed to serve on it ; he did not influence the Committee beyond enumerating certain statistics ; but he again sat in the general Conference, and his impassioned appeal, made towards the close of the discussion, decided the vote given : so that, in effect, the English Government delegates actually led the way—though charged to abstain.

The issue was one of the first importance to Australia and Canada, as the interests of probably 70,000 persons in S. Australia, connected with the Broken Hill Mines, were most seriously at stake. Every vote was known to be of consequence, yet the urgent appeals made to the Home Government for their aid met with no response, and in the end, through English action, the vote taken was against the interests of the Dominions. "A Committee had been appointed to deal with the matter," was always the answer. No such Committee should have been appointed, when the Conference was pending. If we are to study the best interests of our Empire, it will not do to manage or mismanage things in this way; in future some concerted policy should be arrived at, in advance, between the several units.

I was present at all meetings and Conferences, during a month, in the capacity of Scientific Advisor to the Australian Employers delegate. Having travelled from Perth to Port Darwin, almost the whole way round the great island continent, I had feeling on the issue as affecting Australia, apart from my intimate practical acquaintance with the subject.

I gave my opinion of the Conference, soon after my return, in articles in the *Westminster Gazette* and *Morning Post*. I have never had a more interesting opportunity of studying human nature and its vagaries.

The Committee, at first, was a bear-garden, without leadership, without policy, composed of three disparate sections, representative of (1) Government (2) Employers (3) Labour, eight of each. Labour loudly proclaimed itself to be against the employer. Yet one of the British Labour delegates proved to be an exceptionally broad-minded, reasonable and reasoning man; another came forward in the Conference and was eloquent in counselling rational consideration of all matters under discussion. There was no reciprocal feeling of antagonism on the employers' side—on the contrary, every desire to discuss issues from all possible points of view and in the interests of labour. Like Governments, their representatives sat on the fence—especially in open Conference—but tended to come down on the side of sentiment. The advisors present could speak only when spoken to—by request from the chair.

At the end of the eight sitting I lost all patience and mutinied, and thus obtained leave to speak in Committee. I tabled the following motions:—

Inasmuch as no proof is given that a generally effective substitute for white lead in painting has been found;

Inasmuch as the diagnosis of the diseases incident to the painter's occupation is in a state of uncertainty and it is in no way established that the cases of poisoning by lead are exceptionally numerous;

Inasmuch as it is generally admitted that the chief source of risk to painters is dust and there is reason to believe that the production of dust will be overcome by a process of wet rubbing down, such a process having been devised and effectively used;

This Commission is of opinion that it is neither necessary in the interests of the painter for the protection of his health, nor desirable in the interests, either of users or of producers, to conclude an international convention for the prohibition of white lead in painting.

This Commission further considers that the risks incidental to the painter's occupation will be entirely overcome by the acceptance of a convention with the following objects in view:—

(*a*) The prevention of diseases arising from
    (1) Paint dust of all forms;
    (2) Vapour arising from volatile materials;
    (3) Uncleanliness.
(*b*) Medical examination.
(*c*) Notification and certification of all cases of lead poisoning.
(*d*) Distribution of information on the question of the special hygiene of the painting trade.

These represented the feeling in the minds of all the sane people present, who were possessed of the facts and prepared to deal with the issue in a reasonable manner. Ultimately, they were embodied in the majority report, which was carried, however, only by a small vote, no English Government vote being given and all the labour members abstaining. Consequently, in the Conference, the issue presented was contentious; but the report was only "not carried" by a single vote, in Conference—no English Government vote was cast.

The discussion in full Conference occupied nearly four sittings and was of a most discursive character, quite unsuited to the settlement of so important an issue. Gross exaggeration as to the evils of white lead was indulged in by some speakers, and sentiment was the ruling force. It was made clear, that the dust produced in dry rubbing down was the real source of danger. The medical evidence was hopelessly involved, the Germans especially showing themselves to be extraordinary conservative and behind the times; their resentment of non-professional criticism was amusing.

Several amendments, recommending either the total prohibition of the use of white lead or its restriction to external use were proposed and put to the vote; it was clear that even the latter could not be carried, and there was the possibility that nothing would be done and that the conflict would have to go on. At this stage, Dr. Legge made his appeal, advocating the adoption of an amendment prohibiting the use of white lead in internal painting, foreshadowing that this would put an end to the struggle. The compromise was agreed to, on the spur of the moment, without counting the cost to the public and forgetting that the United States of America, the largest producer and user of white lead, was not represented and had not been consulted. The published verbatim report of the Conference contains a full account of the proceedings other than those of the Committee, but the "atmosphere" in which we lived is unpainted.

(*to be continued.*)

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

OUR NEW PAPER has now received its first baptism of criticism and on the whole I do not think its promoters can feel other than gratified at its reception. It certainly is the staple subject of conversation when chemists meet, and this is all to the good. It has created fresh interest in the Society and its doings and no Society can hope to live unless from time to time some new stimulus is given to its activities. I have yet to hear anything in the nature of serious criticism. Some of my friends who might have been expected to view the change with some degree of scepticism are among the first to insist that such a change must not be judged hastily and that the new editor and his staff must be given time to adjust themselves to the new conditions.

THE THERM ENQUIRY drew me for an hour or so the other morning. I wanted to see the Committee described last week by Professor Armstrong as the "men who have no knowledge of the subject they are to consider." Be that as it may, advantageous or otherwise, they seem to have a "nose" for mendacity, and the evidence placed before the Committee is sifted with some care. Judging by what I heard I should be inclined to think that the balance of opinion will give a certificate in favour of the method of charging for gas by the amount of heat units which it contains. This was the question which I thought the Committee had to determine, but various subsidiary questions seem to be raised by many of the witnesses, and perhaps the Committee will have something to say about the price of the therm, which is really what the gas consumers want discussed.

INDUSTRIAL ALCOHOL

I never hear the question of the freer use of industrial alcohol being discussed without thinking of the great pioneer work done by the late Thomas Tyrer. It seems that at last after many years something may be done notwithstanding the added difficulty of the enormously high duty which has to be collected from spirits. Such a duty makes the relaxation of customs restrictions very difficult. On the other hand, the handicap imposed on chemical industry in this country has been so heavy that our continental rivals must have rejoiced in our shortsighted policy. What is really wanted is some alteration in the unduly restrictive regulations which are enforced in the most rigid manner. There are directions in which I think, subject to suitable financial safeguards, these might be relaxed. In the first it should be possible to allow a manufacturer a little more latitude when a new process just past the small experimental stage is being tried out on the works scale. In the second there should be a wider choice of denaturants in order that the cost of production may be kept down. To insist upon the use of a particular denaturant when it necessitates two additional processes in the course of manufacture of a chemical may be typically British, but it is not business.

THE MEETING AT STOREY'S GATE last week in which the London Section joined with the Biochemical Society pleased me immensely. We were not told very much which was new but the personality of the speakers and the intensely interesting nature of the subject held my interest to the end. I picked out two points, as journalists do, which I thought I would watch in future. One was introduced by Dr. Gowland Hopkins and referred to the possibility of "educating" the tiny bacteria to produce what was wanted. Perhaps "educating" is not the best word, because the Professor went on to explain that he got what he wanted by selecting the individuals in a colony which could best carry out his work. The other was mentioned by Professor Harden, who seems to be an economist as well as a biologist. He advocated an investigation into the use of dead organisms in order to avoid the need of food for the live organism and to reduce the complications due to growth. We must remember these two points.

THE BRITISH EMPIRE EXHIBITION which is not to be held until next year, is already being talked about in chemical circles, and I am wondering whether we shall rise to the height of our opportunity. The business side of the Exhibition is sure to be well done, you can trust the Association of British Chemical Manufacturers for that. But what about the science on which the industry is founded and without which the industry could not exist? Will the progress of the science be illustrated as well as the progress of the industry? Will the scientific societies combine in such a way as to make this possible? I hope so, indeed; and it seems to me that the best way to bring this about would be for our own Society to make a beginning by suggesting how the thing can be done. Every society could contribute something to the pot, and would do so, I think, if once a start were made.

[The Society of Chemical Industry has already appointed a Committee to consider this matter, as reported in the account of the Council Meeting appearing in this week's issue.—Editor, C. & I.]

FORTHCOMING EVENTS

Jan. 22. INSTITUTION OF ELECTRICAL ENGINEERS, Savoy Place, Victoria Embankment, W.C. 2, at 7 p.m. "Insulators and Insulating Materials." Discussion opened by Mr. A. G. Warren.

Jan. 23. SOCIETY OF CHEMICAL INDUSTRY, *Birmingham and Midland Section*, the University Buildings, Edmund Street, Birmingham, at 7 p.m. "Some Aspects of the Fuel Problem," by Dr. C. H. Lander, F.I.C. "The Thermal Efficiencies of Manufacture of Different Grades of Gas," by Dr. A. Parker, F.I.C.

Jan. 23. THE ROYAL INSTITUTION OF GREAT BRITAIN, 21, Albemarle Street, W. 1, at 3 p.m. "Colloid Chemistry," by Prof. F. G. Donnan.

Jan. 24. ROYAL SOCIETY OF ARTS, 18, John Street, Adelphi, W.C. 2, at 8 p.m. "The New Methods of Crystal Analysis, and their Bearing on Pure and Applied Science," by Sir William Henry Bragg, K.B.E., D.Sc. The "Trueman Wood" Lecture.

Jan. 25. SOCIETY OF DYERS AND COLOURISTS, *London Section*, Dyers' Hall, Dowgate Hill, E.C. 4, at 7 p.m. "The Application of Colours to Leather," by T. E. Bradbury.

Jan. 26. ROYAL INSTITUTION, Albemarle Street, W., at 9 p.m. "The Machinery of Anti-Bacterial Defence," by Sir Almroth Wright, K.B.E.

Jan. 31. UNIVERSITY OF LONDON, University College, Gower Street, W.C. 1, at 5 p.m. "Radioactivity and X-Rays," by Professor Sir William Bragg, K.B.E., F.R.S.

Jan. 31. ROYAL SOCIETY OF ARTS, 18, John Street, W.C. 2, at 8 p.m. "The Relation Between Chemical and Antiseptic Action in the Coal-Tar Dyes," by Thomas H. Fairbrother, M.Sc., F.I.C., and Arnold Renshaw, M.D., D.P.H.

Feb. 1. SOCIETY OF CHEMICAL INDUSTRY, *Bristol Section*, Chemical Dept., The University, Woodland Road, Bristol, at 7.30 p.m. "The Necessity for a Change in the Milk Standard," by Edward Russell.

Feb. 1. SILVANUS THOMPSON MEMORIAL LECTURE, Technical College, Leonard Street, E.C. 2, at 7.30 p.m. "The Basis of Wireless Communication," by Sir Oliver Lodge, F.R.S. To be followed by a Conversazione and Reunion of Old Students.

Feb. 1. THE ROYAL INSTITUTION OF GREAT BRITAIN, 21, Albemarle Street, W. 1, at 3 p.m. "Photo-synthesis of Plant Products," by Prof. I. M. Heilbron.

Feb. 2. THE ROYAL INSTITUTION OF GREAT BRITAIN, 21, Albemarle Street, W. 1, at 9 p.m. "Fact and Phantasy in Industrial Science," by Mr. C. F. Cross, F.R.S.

Feb. 2. SOCIETY OF CHEMICAL INDUSTRY, *Manchester Section*, Textile Institute, 16, St. Mary's Parsonage, Manchester, at 7 p.m. "A New Process for the Manufacture of Sodium Thiosulphate," by Luke Hargreaves, Esq., and Dr. A. C. Dunningham. "Considerations Relating to the Choice of Materials for Stone Dusting of Mines, with special reference to Carbonate of Lime," by A. C. Dunningham, D.Sc. "Some Developments in Gas Producers," by T. Roland Wollaston, M.I.M.E.

SOCIETY OF CHEMICAL INDUSTRY

MEETING OF COUNCIL

The monthly meeting of the Council was held on January 12, 1923, under the chairmanship of the President, Dr. E. F. Armstrong, F.R.S.

The President reported that the section of the British Empire Exhibition (1924) allocated to the various chemical industries was to be organised and managed by the Association of British Chemical Manufacturers, which had set up an advisory committee to deal with these matters and also with scientific educational propaganda relating to the industries. It was agreed to appoint a sub-committee consisting of Dr. Levinstein (chairman), Messrs. Baker, Carr, Evans, and Hinchley to receive and consider suggestions from any members of the Council, and to submit to the advisory committee a scheme for organising such propaganda.

The Council heartily supported a proposal to hold joint meetings of the Local Sections of the Society and the Faraday Society.

The President was appointed representative of the Society on the General Council of Honour of the International Air Congress to be held in London in June, 1923.

The reports of the Hon. Treasurer and of various Committees of the Council, and other routine matters, were submitted and discussed. Forty new members (25 home and 15 overseas) were elected.

Owing to the difficulty experienced by many members in paying their subscriptions, through unemployment and stagnation in industry, the Council last year approved a scheme whereby members who had been unable to pay their subscriptions for 1921 are allowed to resume their membership at any time before the end of 1923 without payment of arrears of subscription or a second entrance fee. This scheme is now extended to include those who have been unable to pay their subscriptions for 1922.

It was intimated that an award of the Society's Medal will be made this year, and the matter will be discussed at the next Meeting of Council, which will be held on Friday, February 9.

The Council also considered a recommendation from the Publications Committee that the Transactions in future be printed in the large type which is already used for articles in this section of the *Journal*. After consideration of the extra expense involved and other matters it was agreed that the recommendation be adopted and the Editor was desired to make this change so soon as the Transactions already set up had been published.

NEWS FROM THE SECTIONS

OTTAWA SECTION

Mr. F. J. Hambly presided over the meeting held in the University Club on December 15 and read a letter from the President, Dr. E. F. Armstrong, which was much appreciated by those present. After discussing the question of obtaining publicity, the hon. secretary and Mr. Gilmore were appointed a committee to report on the possibility of co-operating with the local Press. The chairman invited the associate members to take up full membership, and urged that every effort should be made to increase the membership of the Society. Dr. Macintyre gave an outline of the decision to publish the Society's *Journal* weekly instead of fortnightly.

An address on "Indicators" was given by Prof. Waddell, who showed that acid indicators change colour at a hydrogen-ion concentration above 7 and basic indicators at a concentration below 7. The meaning of hydrogen-ion concentration was discussed and illustrative experiments performed. The speaker stated that, although the evidence was not conclusive, in some way the hydroxyl-ion acts when the hydrogen-ion concentration is above 7 and the H-ion when it is below 7.

Mr. C. H. Robertson showed apparatus used for determining hydrogen-ion concentration at the Farm Laboratory, described methods used in connexion with soils, milk, canned goods, etc., and suggested that a determination of the hydrogen-ion concentration of soils would give a more correct indication of the soil reaction and that there seemed to be a definite connexion between the hydrogen-ion concentration of flour and its baking value.

BRISTOL SECTION

The meeting held on December 7 was the first of the Joint Meetings under the scheme for co-operation with the Chemical Society. Prof. F. E. Francis presided over a good attendance and three papers were read.

Prof. Francis described the work on the composition of paraffin wax which is being carried out under his direction, and stated that investigation of the speed of oxidation had given curious results.

In a paper on "Bee Wine," Mr. J. H. Skelton, B.Sc., said it had long been known that certain types of wild yeast, such as those constituting the "wine beer" or "ginger-beer" plant, would produce alcohol from saccharine solutions. Careful examination of samples of the alcoholic liquor produced in this way showed that, contrary to the general opinion, it contained neither fusel oil nor methyl alcohol, the chief products present being alcohol, acetic acid, water, acetaldehyde, and acetone (traces). On keeping, the "wine" was liable to ferment, the alcohol content increasing under certain conditions to 17 per cent., or nearly double the average content. The organisms causing the fermentation consisted mainly of the spherical *Saccharomyces*, known in industry as the "bottom" yeast of wine, and the rod-shaped *B. aceti*.

In conclusion Prof. J. W. McBain gave an account of current chemical research at Bristol University.

MEETINGS OF OTHER SOCIETIES

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held on January 11, Sir Max Muspratt, Bart., in the chair. A letter was read from Dr. Charles Carpenter, the first chairman of the Association, intimating his desire to retire from the Council owing to pressure of other duties. The letter was received with the greatest regret, and the chairman informed the Council that he only acquiesced after ascertaining that Dr. Carpenter could not reconsider his decision. The Council placed on record the great debt of gratitude which the Association owed to Dr. Carpenter for the valuable work which he did in connexion with the formation of the Association and elected him an honorary vice-president for life. Dr. Clayton, M.P., was elected to fill the vacancy caused by Dr. Carpenter's retirement. Various routine matters were disposed of and the Anchor Chemical Co., Ltd., was admitted to membership.

A report from the general manager on the progress made in organising the chemical section of the British Empire Exhibition (1924), stated that over 20,000 sq. feet of space had already been earmarked for 44 firms and that the Society of Chemical Industry was taking a leading part in promoting a scientific portion of the section. Reports on the Dyestuffs Act and the Safeguarding of Industries Act were presented, the perennial question of alcohol for use in industry was discussed, and the use of tar on roads also received attention. In view of the inadequacy of the statistics available of the chemicals imported into this country the general manager was given instructions to endeavour to bring about an improvement. Transport matters were discussed and the Society's new venture, *Chemistry and Industry*, received attention.

ROYAL SOCIETY OF ARTS

At the meeting held on January 17, Dr. T. M. Legge presiding, Mr. C. A. Klein read a paper on "Hygienic Methods of Painting: the Damp Rubbing-down Process."

Dust is known to be the main source of lead poisoning in industrial work, and of the different operations carried out by the painter that of dry rubbing-down is the most productive of dust. A large number of determinations has been made of the quantity of dust in the air breathed by a painter engaged in rubbing surfaces covered with white-lead paint. These determinations were made in London, Manchester and Brimsdown during ordinary painting work and showed that the quantity of dust produced in the rubbing or subsequent dusting of the surface is dependent on a large number of factors, amongst which may be mentioned age of film, condition of surface, finish of paint, *i.e.*, whether flat or glossy, and in addition, variation in the personal factor of different painters. The variation in quantity of dust observed in no way affects the main issue, for it was shown that dry rubbing-down and all the operations connected therewith are dangerous, *i.e.*, give rise to dust in the vicinity of the worker's mouth, containing more than 2 mg. of lead per 10 cb. m. (the safety limit), and it is clear that the proposed prohibition of the process is entirely justified. Microscopic examination of paint dusts show the presence of appreciable quantities of ground abrasive in addition to the dust of the paint film, both being present in particles of varied size. It is suggested that in view of the high silica content of the dust of abrasive particles, particularly when flint is used, such particles as are less than 12μ may enter the lung and prove a contributory agent in causing the high incidence of respiratory diseases from which the painter is known to suffer.

Investigations were described leading to the development of a damp process for rubbing-down all painted surfaces, the process suggested being to sponge the surface with water, followed by rubbing with a waterproof sandpaper; the powdered paint dust is then removed by means of a wetted sponge and the surface allowed to dry prior to painting. The limited quantity of water used has proved to be an efficient dust preventative, and it also avoids the objectionable features of the old established wet process of rubbing-down in which large quantities of water were used, under conditions not suitable for general paint work. The process has been developed in consultation with master and operative painters and is regarded by them as wholly practicable for all classes of work. The waterproof sandpaper recommended is entirely unaffected by prolonged immersion in water, and arrangements are being made for its manufacture in this country at an early date. In collaboration with the Home Office, the Industrial Joint Council of Painters and Decorators has framed regulations in reference to the use of lead paints as required by the white-lead convention agreed at the International Labour Conference in Geneva, 1921. These regulations, which are designed to reduce the risk of lead poisoning amongst painters, provide that surfaces painted with lead paint shall not be rubbed down or scraped by a dry process. It is felt that proper observance of the regulations will adequately deal with the lead problem in painting, and further, it is suggested that having regard to the possible ill effects of the dusts of abrasives, the process of damp rubbing-down should be applied to all painted surfaces, irrespective of the character of the paint material.

MATTER AND ENERGY *

By SIR W. J. POPE, K.B.E., F.R.S.

A VERY serious difficulty usually confronts the individual entrusted with the onerous duty of delivering a commemorative address upon some great man who has long since passed away; the difficulty might at first sight appear particularly formidable in connexion with the James Watt Anniversary Lecture which, by the pious care of the Greenock Philosophical Society, has been delivered annually for nearly sixty years past. It might naturally be expected that so long a series of memorial lectures had thoroughly exhausted every aspect of the activities of the subject of the memorial and that nothing fresh remained to be said.

This, the ordinary source of embarrassment on occasions of this kind, does not exist in connexion with the Watt commemoration; Watt was a great pioneer, he created new and fruitful methods of applying science and scientific knowledge to practical purposes, and indeed left his own specific province as an engineer to make a valuable contribution to chemical science—the determination of the composition of water—which will ever retain a place in the history of chemistry. The inventive genius of Watt converted the rudimentary steam-engine of Newcomen into a prime mover with many obvious applications; it revealed for the first time that the potential energy resident in coal could be harnessed in such a way as to render prodigious quantities of power available for the replacement of human or animal labour. It paved the way, directly, for all the great developments of the steam-engine which have occurred during the last 150 years and, indirectly, for that vast expansion of the application of the energy resident in fuel which has resulted in the device and perfection of such forms of prime mover as the internal-combustion engine and dynamo-electric generators.

The history of scientific progess shows that from time to time the centre of most intense interest changes, and often changes very abruptly; a discovery of fundamental importance is frequently made which directs experiment and study into a new and fruitful province and a rapid expansion takes place in the scientific outlook upon the universe as a whole. Such new great acquisitions of knowledge do not invalidate previous knowledge. In view of this incessant accretion of knowledge it is very interesting to contrast our present situation with that of one or other of our great predecessors; such a comparison shows how Watt conquered a situation which was obscure to him, but is now quite clear to us and teaches how the obscure problems confronting science to-day may best be faced In the Newcomen engine steam was used merely for the purpose of producing a vacuum in the cylinder; the power was generated solely by the external pressure of the atmosphere forcing the piston down to the bottom of the cylinder. In his double-acting engine Watt was using the expansive power of steam to force the piston both up and down. He had succeeded for the first time in converting into useful work the energy resident in the fuel employed in heating the boiler. A new subject for study and a new principle for application to useful purposes had presented themselves to the practical engineer, namely, the conversion of heat into work, and there is much evidence to show that Watt pondered deeply upon the nature of the novel effect which he had obtained.

---

* Extracted from the James Watt Anniversary Lecture delivered before the Greenock Philosophical Society on January 12, 1923.

The history of the development of the physical sciences up to the end of the nineteenth century shows that it has been very gradually and slowly realised that inanimate nature is built up from two utterly distinct kinds of things, namely, matter and energy. One of the favourite topics for discussion among philosophers of all ages has always been the problem of determining what are the primitive materials from which the universe is built up: stated in a simple form the problem resolves itself into the question of what elementary things would be required as the materials from which to construct a universe identical with the one in which we live.

The Greek philosophers considered this problem in the light of pure reason, and concluded that it could be solved by mere discussion. A definite stage in their treatment of the question was perhaps marked by Empedocles who, five centuries before Christ, declared that four elements or primordial materials can be distinguished, namely, air, water, earth and fire; the elements distinguished by the ancients represented the various conditions under which matter presented itself to them, namely, as solids, liquids and gases and the state of burning. This rudimentary conception of the ultimate constitution of the universe probably did not originate with the Greeks; the oldest Indian writers adopted the same four primitive elements with the addition of a fifth, which they termed the ether, whilst Buddha named consciousness as a sixth element. Ancient Greece probably had but little use for scientific thought, and may well have regarded it as an occupation for men of ability who were temperamentally incapable of promoting the general artistic tendencies of their race. The writings of the Greek philosophers concerning the constitution of the universe show that they perceived vaguely one defect in their views. They had fairly clear ideas about matter—matter is anything which possesses weight—but the something which is always associated with matter and by means of which matter makes its existence known. namely, energy, escaped their powers of definition. We now know that energy is just as much a part of the universe as is matter: its existence is just as real as that of matter: it can be measured, transferred from one material body to another, converted into various forms, and indeed can be bought and sold just like solid matter itself. Little further progress could be made until Francis Bacon at the end of the sixteenth century accentuated, though he did not himself discover, the principles of the modern method of scientific enquiry. Although Bacon himself was a philosopher and not an experimenter, and although he made the most ineffective use of the tools which he did so much to perfect, his authority as Lord Chancellor of England and his eloquence as a writer gave a tremendous impetus to the experimental method of scientific inquiry, and may be said, for all practical purposes, to mark him as the founder of modern science.

The inauguration of the experimental scientific method led to rapid progress and, by the middle of the eighteenth century. the conception of a chemical element was firmly established; it became evident that nature has provided a number of distinct unit materials to which the name chemical elements is given and from which the multitude of substances contained in the universe are compounded. At the same time, it was apprehended that something more than mere matter was included within the purview of natural philosophy, and the German chemist Stahl defined this something as the element phlogiston, the combustible principle. In the notion of phlogiston we can discern a striving after the modern conception of energy; the phlogiston theory was in its prime in the days of Watt but it was so defective, particularly in its view that phlogiston is a material element identical with hydrogen, that it was overthrown by the French chemist Lavoisier towards the end of the eighteenth century. The phlogistonists regarded heat as a ponderable substance, and this error which wrecked the phlogiston theory, was escaped by Lavoisier, who concluded from his experimental results that the transference of heat to or from a body involved no measurable change in weight. At the same time, and in spite of its imponderability, heat was to be understood as something which could be measured. Although James Watt lived throughout the period of greatest ascendancy of the phlogiston theory, he seems always to have been perfectly sound on the question of the essential character of heat; in fact, the modernity of his conception of heat is suggested by the contemporary law which bore his name. Watt's Law states that "the quantity of heat which is required to convert a pint of water at a temperature of zero into steam, is the same whatever be the pressure"; such an enunciation is hardly compatible with ardent faith in the phlogiston hypothesis of Stahl, and at the same time it is noteworthy that the statement presumes nothing concerning the nature of heat. In 1803 John Dalton enunciated the atomic theory; he accepted the view that nature has provided a certain number of distinct materials, the chemical elements, from which the material universe is built up, and stated (1) that every element is made up of homogeneous atoms whose weight is constant, and (2) that chemical compounds are formed by the union of the atoms of different elements in the simplest numerical proportions. We know now that the number of chemical elements is limited to 92 different species, but that the number of compounds is practically unlimited, some hundreds of thousands having been already prepared and examined.

The most searching experimental tests of the validity of the atomic theory have merely consolidated its position as the basis of modern chemistry, but it was long before equally clear conceptions were formed concerning the more elusive accompaniment of matter, namely, the phlogiston of Stahl or the energy of modern times. The fact that mechanical work could be measured was familiar in the eighteenth century, and indeed Watt assigned to one horse-power the very liberal estimate of 33,000 foot-pounds per minute, the foot-pound being defined as the work done in raising a weight of one pound through a vertical height of one foot; when looked at in this way mechanical work is seen to be a mode of motion. It was also known that a given output of mechanical work by a steam-engine necessitates a definite consumption of fuel, but no adequate conception had been formed of heat as merely another form of mechanical work. Many eminent scientific men, and among them Newton and Davy, believed that heat was not material but was a form of motion; the general opinion prevailed, however, that heat is a material fluid to which the name "caloric" was applied. The material theory of the nature of heat prevailed up to about 1850; even in 1848 Lord Kelvin reaffirmed his belief in it and stated that "the conversion of heat (or caloric) into mechanical effect is probably impossible, certainly undiscovered. In actual engines for obtaining mechanical effect through the agency of heat we must consequently look for the source of power, not in any absorption of conversion, but merely in a transmission of heat." Towards the middle of the nineteenth century Dr. J. P. Joule, the first of the Watt Anniversary lecturers showed that mechanical work can be converted into an equivalent quantity of heat; he showed experimentally that the amount of heat necessary to raise the temperature of one pound of water by one degree Fahrenheit is generated by the expenditure of 770 foot-pounds of mechanical work. The work of Joule led rapidly to the replacement of the material theory of heat by the mechanical theory of heat, to the realisation that all forms of energy—mechanical work, heat, light, and electricity—are interconvertible, and in fact to the development of the modern science of thermodynamics upon which is based all progress in the construction of prime movers. Lavoisier had shown long before that matter retains its mass unchanged throughout any series of chemical reactions and so established the principle of the conservation of matter: the work of Joule led to the establishment of the principle of the conservation of energy, namely, to the proof that whilst a given quantity of energy can be converted into various forms, such as heat, light, electricity and mechanical work, its quantity remains unchanged. In fact, neither matter nor energy can be either destroyed or created.

The story of this dramatic development in scientific knowledge has been told by Sir Dugald Clerk in the first Joule memorial lecture at Manchester in 1920; the fact that many of us were acquainted with men like the late Lord Kelvin, who in their younger days opposed the mechanical theory of heat, is a striking testimony to the rapidity of scientific progress during the nineteenth century. The first few years of the present century have brought even more startling developments in our knowledge of matter and of energy. Dalton put forward the atomic theory in 1803, stating that any chemical element consisted of very minute and similar particles which he termed atoms. Some 90 chemical elements are now known and the weight of the atom of each has been determined in terms of the weight of the atom of the lightest element, hydrogen; thus, the atomic weight of hydrogen being taken as 1, that of oxygen is 16, of iron 55·8, and so on. These chemical elements represent the 90 or so primitive forms of matter provided by nature from which all compound substances are built up; in accordance with the law of conservation of matter, a given weight of a particular element can be traced through innumerable chemical reactions, the weight never varying and the quantity of the element remaining unchanged. So far as could be seen, the atoms of the elements constituted the immutable and ultimate units of matter from which the whole universe was constructed.

(*To be continued*)

CORRESPONDENCE

SALVARSAN DIGLUCOSIDE

Sir,—A paper by A. Aubry and E. Dormoy, describing an arsenical glucoside, diglucosidodihydroxydiaminoarsenobenzene, appears in *Comptes Rendus,* November 6, 1922, pp. 819 to 822.

This paper calls for comment, as the preparation of the glucoside referred to is covered by a patent held by the writer and Boots Pure Drug Co., Ltd., Nottingham.

During the last two and a-half years extensive clinical trials of this compound have been carried out, and an account of the preparation and chemical characteristics, as well as of the therapeutic results obtained, will be given in a paper to be read shortly before a joint meeting of the Chemical Society and the Society of Chemical Industry in Nottingham.—I am, Sir, etc.,
Leonard Anderson

Fine Chemical Department,
Boots Pure Drug Co., Ltd.,
Nottingham
January 10, 1922

PERSONALIA

The University of Prague has conferred the degree of Doctor in Natural Science on Mr. J. G. F. Druce, M.Sc., A.I.C., who is the first Englishman to obtain this degree.

Dr. Charles Carpenter, a former President of this Society, and the first Chairman of the Council of the Association of British Chemical Manufacturers, has resigned his seat on the latter body owing to pressure of other duties, and Dr. Clayton, M.P., has been elected to fill the vacancy thus created.

Dr. E. C. Franklin, professor of organic chemistry at Leland Stanford Junior University, has been elected president of the American Chemical Society, in succession to Dr. E. F. Smith. In addition to his professorial duties, Dr. Franklin has had much industrial experience, and his work on liquid ammonia as an electrolytic solvent is widely known.

On the nomination of the Association of British Chemical Manufacturers the Board of Trade has appointed Mr. W. H. Dawson, manager of the British Alizarine Co., Ltd., to be a member of the Dyestuffs Advisory Licensing Committee in place of Mr. E. V. Evans, O.B.E., who has resigned. The place left vacant on the Dyestuffs Industry Development Committee by the resignation of Mr. Evans has been filled by the appointment of Mr. L. Blundell, of the North British Chemical Co., Ltd.

Dr. P. Freiberger has been appointed chief of the Dye Investigation Laboratory of the Customs Division of the U.S. Treasury. Prof. R. T. Haslam has succeeded Dr. R. E. Wilson as director of the Research Laboratory of Applied Chemistry of the Massachusetts Institute of Technology, and Prof. W. G. Whitman has been appointed assistant director of the same laboratory. Mr. Jerome Alexander has opened an office in New York as consulting chemist and chemical engineer. Messrs. J. M. Weiss and C. R. Downs, formerly director of development and chief chemist, respectively, to the Barrett Co., and recipients of the H. N. Potts medal of the Franklin Institute, have also established themselves in New York as consulting chemists and chemical engineers.

The Paris Academy of Sciences has made the following awards of prizes for 1922 :—Montyon Prize of 2500 francs to the late Charles Boulin for his researches on mustard gas ; an honourable mention (1500 fr.) to Louis Tampier for his work on the manufacture of poison gas ; the Jecker Prize to Marcel Godchot (5000 fr.), Marc Bridel (2500 fr.), and Georges Tanret (2500 fr.) for their researches in chemistry ; the La Caze Prize to Paul Thiébaud Muller for his researches in physical chemistry ; the Cahours Foundation to Andrée Chaudun for her physico-chemical work on the inversion of sugar ; the Houzeau Prize to René Dubrisay for his work on solutions ; the Victor Raulin Prize to Louis Longchambon for his researches on the relation between rotatory power and crystalline symmetry ; the Bellion Prize to Arthur Vernes for his researches on the measurement of flocculation by photometry ; the Philipeaux Prize to Costantino Gorini for investigations on lactic fermentation ; and the Alhumbert Prize to Charles Mauguin for his researches on liquid crystals. In addition the Jérome Ponti Foundation has been awarded to Pierre Mahler for his work on fuels, the H. le Chatelier Foundation of 5000 fr. each to Paul Riou, Ernest Torporescu, and Paul Mondain-Monval for researches on the manufacture of sodium carbonate by the ammonia process, and to Pierre Lafon for researches on the enamelling of iron.

* * *

From Germany the death is announced of Prof. A. Fischer, a well-known investigator and teacher, and author of a treatise on "Rapid Methods of Electroanalysis."

The deaths are reported from Italy of Prof. G. Parrozzani, professor of pharmaceutical chemistry in the Royal Technical Institute, Aquila, U. Cattaneo, director of the Research Institute of the Italian State Railways, and Prof. L. Marino-Zuco, professor of applied chemistry in the Royal School of Engineering, Pisa.

Out of a total of 90,000 students in German Universities, states the *Chemiker-Zeitung,* about 40,000 obtained employment in trade and industry during the summer vacation, and of this total 15,000 secured work in mines.

NEWS AND NOTES

SOUTH AFRICA

Development of the Iron and Steel Industry

Considerable interest attaches to the reported amalgamation of the Union Steel Corporation, of Vereeniging, and the South African Iron and Steel Corporation, of Pretoria, as with the removal of internal competition, the industry will be less handicapped in facing foreign competition. The Union Steel Corporation has been a producer for several years, but has utilised little South African ore; and recently it was announced that the Pretoria company intended to erect a plant at a cost of £2,500,000 to produce 75,000 tons per annum. As a Government bounty is granted of 15s. per ton on pig iron plus 15s. per ton on steel when the output from South African ore reaches 50,000 t., active development should result from the amalgamation.—(*Min. Mag.*, *Dec.*, 1922.)

UNITED STATES

Tin in 1919

According to the United States Geological Survey, the production of tin concentrates in the United States in 1919 was limited to Alaska, where concentrates with a recoverable content of 56 t. of metallic tin were won from gravels. Development work and prospecting for tin was continued in South Dakota and New Mexico, but no production was recorded. The output of metallic tin from the six smelting plants in operation was 12,236 t., almost entirely from Bolivian concentrates. Imports of ore and metal amounted to 19,196 t. and 44,849 t. respectively, and the export of tin was 306 t., so that 56,779 t. of primary tin was available for consumption.

GERMANY

Utilisation of Waste Heat

At a meeting of the Saxony and Anhalt branch of the *Verein Deutscher Ingenieure* held at Dessau on October 12, a paper on waste-heat utilisation was read by O. Brandt, director of the Abwärme-Ausnützung and Sauggas G.m.b.H. ("Abas"), referring particularly to plant made by this firm.

As the result of efficient ventilation and removal of dust from workshops the quantity of heat required to warm them in winter is greatly increased. For the supply of this heat, there is available the exhaust steam from engines and turbines, and the flue gases of boilers and furnaces. Flue-gas-air heat-exchangers can be used if the temperature of the flue-gas is about 500° C., *e.g.*, in conjunction with steam boilers, glass and porcelain furnaces, drying-ovens, etc. The "Abas" heat-exchanger is of similar construction to the radiator of a motor car, the air being forced by a fan through a number of narrow channels, and the hot gases passing through the intervening space in the reverse direction. The warmed air is then conveyed to the rooms to be heated through metal pipes. An even warmth is more quickly reached and uniformly maintained than with steam heating, ventilation being obtained at the same time.

For flue-gases with a temperature above 500° C., such as are produced in smelting ores, cement manufacture, various large-scale chemical processes, and by large gas engines, a waste-heat boiler should be used. The steam generated depends on the quantity of gas available and its temperature. A 3000 h.p. blast furnace gas-engine which worked 7200 hrs. per annum and was fitted with a waste-heat boiler, produced 18,360,000 kg. of steam at 15 atmospheres pressure and 350° C.

A heat-exchanger for warming air with exhaust steam is constructed of a battery of galvanised wrought-iron pipes through which the air passes, the steam passing between them. Air may similarly be heated with hot water derived, for example, from an economiser. Although the use of economisers of any kind in a boiler flue may impede the draught to such an extent as to render a fan necessary, the author said that the use of chimney draught alone was now always uneconomic.

GENERAL

Institution of Structural Engineers

With the advent of concrete, reinforced concrete, and special steels, a specialised profession, that of the structural engineer, has been developed during the past few years, so that civil engineering is now divided under three main heads—electrical, mechanical, and structural. Of these divisions the first two have long been represented by powerful professional institutions, and the structural division has been represented for many years by the Concrete Institute. By permission of the Board of Trade this Institute has now changed its title to the Institution of Structural Engineers, the more accurately to denote its special function as a professional society for structural engineers. The membership includes Members, Associates, Associate-Members, Graduates, and Students, and admission is by examination through the Graduate or Associate-Membership class. The address of the Institution continues for the present to be Denison House, Vauxhall Bridge Road, London, S.W. 1, but it is understood that in the near future the Institution may acquire premises of its own.—(*Bd. of Trade J.*, *Jan.*, 11, 1923.)

"Santoperonin"

In a recent number of the *Chemiker-Zeitung* (1922, p. 993), A. Marx describes under this name a new anthelmintic, which apparently combines in itself the virtues of all the anthelmintics already in use, and is unique in being effective against all the common forms of intestinal worms. There is no reference in the article to the drug having been patented, and the description given of its constitution is so vague that the probability of the assertions made regarding its therapeutic value cannot be judged. The inventor apparently began with the remarkable assumption that since methyl alcohol is toxic it must be the methyl groups in santonin that are the cause of this drug's toxicity. The next step appears to have been based on Karrer's work on filicic acid and its allies, and on Lautenschlager's proof that the vermicidal action of the santonin type of anthelmintic is associated with the presence of a lactone group (*cf.* J., 1922, 467 R), and it was assumed that, by the combination of these two types of structure, the ideal anthelmintic would be produced. The coupling of the two groups is said to be effected by a bridge which itself is vermicidal. All this does not take us very far, but a little more information has been published in other journals, chiefly medical and pharmaceutical, in Germany in which the drug is referred to as a complex derivative of "naphthalene phenolate" containing copper and aluminium acetate. β-Naphthol, phenol, copper sulphate, and aluminium acetate have all been used as anthelmintics before now. The inventor's reticence has already been adversely criticised in Germany, and in the current number of the *Chemiker-Zeitung* (No. 143, p. 1081) Dr. Herrmann states that a specimen of "santoperonin" examined by him yielded 37 per cent. of copper oxide, that the ash contained in addition iron, alkalis, and sulphur, but no aluminium, whilst by heating the drug under reduced pressure a sublimate of salicylic acid was obtained. The copper was easily extractable by 3 per cent. hydrochloric acid. It is difficult to reconcile these results with the vague synthetical picture of "santoperonin" drawn by the inventor, and it is to be hoped that the medical profession in this country will steer clear of "santoperonin" until the discrepancies are cleared up and the inventor has fully disclosed its composition in a patent specification or otherwise.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for January* 11)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Perfumery, rubber goods	65
Canada	Condensed milk plant	*
Cuba	Earthenware, crystal glassware	66
Egypt	Glassware, oil, paint, etc. (tender for)	9701 F.E./ G.P.
„	Photographic materials (tender for)	9726 F,E./ G.C.2
France	Iron and steel	39

TARIFF CUSTOMS EXCISE

Australia.—Under the Iron and Steel Products Bounty Act, 1922, a bounty may be paid, under certain conditions, on specified iron and steel products manufactured in the Commonwealth. Increased import duties are leviable on sugar and syrup. The prohibition on the importation of German books has been revoked and anti-dumping duties have been applied to eau-de-cologne, analytical balances, and gold leaf of German origin.

Austria.—The consumption taxes on alcoholic liquors and sugar have been increased.

Egypt.—Revised import duties have been applied to alcoholic liquors.

France.—From December 31 the export or re-export of scrap iron and steel is prohibited, save under licence, and except to Italy.

Germany.—Particulars of recent decreases in export duties may be obtained from the Department.

Italy.—The official valuations, for the levy of duty, of essential oils, synthetic perfumes, alkaloids, etc. have been revised. Articles which may be imported under the "temporary importation" scheme include paper and brass strips for covering electric cables, raw artificial silk, sheet glass for the manufacture of photographic plates, and sheet aluminium. The sales taxes on perfumes, medicinal specialities, and spirits have been modified.

Mexico.—A modified import duty has been applied to soap.

New Zealand.—Amendments in the Customs Amendment Act, 1921, provide that the duty of 25 per cent. *ad valorem* leviable on certain goods imported from countries whose currencies have depreciated more than 90 per cent., be replaced by an *ad valorem* duty to be fixed from time to time, by Order in Council; and that the nominal value of goods, not of British origin but competing with British goods, shall not exceed by more than 20 per cent. the cost of British goods to the importer if the importation of such goods is likely to prejudice any industry in New Zealand or the Empire.

Rumania.—Recent modifications of the import duties affect skins, leathers, starch and vegetable glues, glucose, vegetable fibres, electric lamps, iron plate, tartaric and citric acids, calcium carbide, and lamp black. Amended export duties have been applied to enamelled earthenware and caustic soda.

Tanganyika.—The customs tariff in operation in Kenya has now been enforced in Tanganyika.

REPORT

REPORT ON FINANCIAL, INDUSTRIAL AND COMMERCIAL CONDITIONS IN CANADA. DATED SEPTEMBER, 1922. *By* G. T. MILNE, *H.M. Senior Trade Commissioner in Canada and Newfoundland. Pp.* 82. *London: H.M. Stationery Office,* 1922. *Price* 2*s.* 3*d.*

During the last twelve months the economic situation in Canada has been marked by price readjustments, as in other countries. It is not anticipated that business will revive greatly this year, but a steady improvement is generally anticipated. Certain tariff modifications are now operative, and should favourably affect imports from the United Kingdom, although reductions in the customs tariff are practically neutralised by the increase in the sales tax. Regulations for the marking of goods to indicate the country of origin have been repealed, but goods specified by Order in Council can be ordered to be so marked.

The output of various minerals during the year was as follows:—

Mineral		Output	Inc. (+) dec. (—) per cent. compared with 1920
Coal	Short tons	15,000,000	— 12
Gold	Fine oz...	924,374	+ 20.8
Silver	,, ..	13,134,926	— 1.46
Copper	Lb. ..	53,500,000	— 33
Nickel	,, ..	less than 20,000,000	— 66
Lead	,, ..	67,000,000	+ 87
Zinc	,, ..	53,000,000	+ 32
Iron	Tons ..	43,000	—
Petroleum	Barrels ..	190,000	—

During the year ended March 31, 1922, the total imports of coal from the United States amounted to 17,162,897 short tons, compared with 20,245,347 t. in the preceding year. About 76·5 per cent of the total output of gold was mined in Ontario, British Columbia ranking second among the gold-producing provinces with a total of 149,397 fine oz., an increase of nearly 20 per cent. compared with 1920. The values of the imports and exports of copper and its products during 1921 were $9,612,526 and $13,314,089, respectively. The average monthly output of pig iron during 1921 was 50,000 long tons, which is less than the monthly average for any year since 1908. Imports of iron ore, chiefly from the United States, for the year ended March 31, 1922, were 656,902 short tons ($1,936,247), as compared with 1,950,291 t. ($5,995,038) in the previous year. For the first time Canadian finished steel products have successfully entered the foreign market. In 1920 the total output of paper pulp was 1,960,102 t. ($141,552,862) and of paper 1,184,225 t. ($136,639,921). The water-power resources of the Dominion are assessed at 18,255,000 h.-p., of which 2,500,000 h.-p. has been developed, and it is estimated that by 1940 the water power harnessed will amount to 5,600,000 h.-p. Practically all industrial centres in Ontario are now served with electric power through the agency of systems built by the Hydro-Electric Power Commission.

The establishment of branch factories in the Dominion is one of the most important factors confronting British manufacturers interested in the Canadian market. The number of United States branch works in Canada is reliably estimated at 675, of which 335 are in Ontario, 185 in Toronto, and 75 in Hamilton. It is anticipated that a comparatively large number of branch works will be established in the Dominion during 1923. Recent industrial projects include the manufacture of asbestos products, dyeing and finishing of textiles in Quebec, and the manufacture of optical and alloy-steel goods in Ontario.

The total imports of merchandise in 1922 were valued at $747,804,332 compared with $1.240,158,882 in 1921. The exports for 1922 were valued at $740,240,680 compared with $1,189,163,701 for the previous year. It is emphasised that owing to the contiguity of the United States, Canada stands in an entirely different position from the other self-governing Dominions in regard to its economic relations with the Mother country. The Canadian market is on this account more difficult for the British manufacturer to cultivate than any other in the Empire. Preference shown by Canadians for British goods is based on their repute for excellent quality, but the distribution of circulars and catalogues is insufficient to maintain this preference.

REVIEWS

GASWORKS RECORDERS. *By* L. A. LEVY. *Pp. xi*+246. *London: Benn Brothers, Ltd.*, 1922. *Price* 35*s. net.*

The author of the book under review is enthusiastic in his advocacy of the use of recording instruments in the control of gas manufacture and distribution. A picture of a gasworks equipped with all the recording devices referred to in this volume might possibly convey a wrong impression of the essential works operations: an impressive foreground would be occupied by recording instruments, gas making and distributing plant would be found somewhere in the hinterland.

Control of processes may be based upon the results of snap-tests or the indications of recording devices. Both methods have inherent disadvantages. It is often too readily assumed that the elimination of the personal element by the substitution of the latter method for the former must lead to increased accuracy and efficiency in the operation of the plant. This is not necessarily so. The value and trustworthiness of a recorder are to be determined by the "acid test": How far is the record influenced by and *only* by variations in the characteristic it is intended to record? The individual observer, more especially when, as sometimes happens, both operation and control of a plant are in his charge, suffers from what may be euphemistically described as his "personal equation." Recording instruments are not without their idiosyncracies. Their reliability increases as the effects of extraneous influences, *e.g.*, friction, temperature and the rest, are eliminated from the record. The lot of those responsible for control of processes would indeed be a happy one, were but one-tenth of the claims advanced on behalf of recorders justified beyond a doubt. Recorders would be everywhere installed, though possibly their cost of upkeep and repair might exceed that of the skilled labour they would displace.

Among the recorders discussed in the volume are pressure and vacuum gauges, pyrometers, gravitometers, gas analysis and volume recorders, densimeters, and volume recorders. The activity, born of the Gas Regulation Act, 1920, amongst makers of scientific apparatus is evidenced by the chapter devoted to recording gas calorimeters. Valuable chapters on the use of recording appliances and on recording mechanism in general are included in the volume. A considerable number of the devices described are due to Mr. J. F. Simmance. Considering that the platinum resistance thermometer is amongst the most accurate of all recording instruments, it is disappointing to find its calibration inaccurately described on p. 62. The concavity of the graph in Fig. 62 giving the relation of resistance to temperature is very much exaggerated and moreover is directed towards the wrong axis. The theory of the Simmance gravity governor developed on pp. 113-117 contains a number of errors, one of which, at the top of p. 115, invalidates the whole of the subsequent argument. The significance of the statement "Let the conditions be such that unit volume at N.T.P. becomes N under other conditions," on this page, is, to say the least, vague. An important feature of Boys's recording gas calorimeter which is not brought out by the statement concerning the chart, on p. 127, is that the calorific value is recorded in strict relation to the chart ruling, however the chart may be displaced on the drum.

The general get-up of the volume is excellent, and the type and illustrations leave nothing to be desired, the line drawings being particularly clear. A considerable portion of the descriptive matter is available gratis in the form of trade circulars. Owing to the extremely high price of the volume, these circulars will probably continue to be the main sources of information referred to by those interested in gasworks recorders. J. S. G. Thomas.

The Analysis of Rubber. *By* J. B. Tuttle. *American Chemical Society, Monograph Series. Pp.* 155. *New York: Chemical Catalog Co., Inc.* 1922. *Price* $2.50.

The finished products of the rubber manufacturer appear on the market in an infinite variety of forms and colours and possess widely different properties, results which are achieved by the incorporation of suitable filling materials or by careful control of the vulcanisation process. It is, therefore, desirable, if not essential, that the analyst who wishes not only to secure accurate data as to the elementary composition of an article but also to be able to interpret the results obtained, should be familiar with the physical and chemical changes occurring during vulcanisation.

The work under review is addressed primarily to those chemists who are engaged in the consumers' laboratories and to those who, without previous experience in rubber analysis, may be called upon to undertake work of this nature. This method of treatment involves the inclusion of much introductory matter not usually to be found in an analytical treatise, and chemists not connected with the industry will thereby be enabled to form a general idea of manufacturing principles.

The earlier chapters deal with the purpose of rubber analysis, with the nature and composition of various types of crude rubber, and with the testing of materials, including organic accelerators, employed in the preparation of rubber compounds. The theory of vulcanisation is briefly discussed and, after some notes on sampling, sections are devoted successively to extractions with acetone and other organic solvents, to the determination of rubber by direct and indirect methods, and to the estimation of sulphur, present in various forms. The book marks an advance on its predecessors in that it contains a brief description of suggested methods for the detection, in manufactured articles, of certain organic accelerators, some hitherto unpublished data being here included. The up-to-date character of the book is further emphasised by the short account of micro-sectioning and photo-micrography (referred to as microphotography), and by the inclusion of glue, in the chapter headed "Mineral Analysis," among the compounding ingredients. In an appendix there is given an account of manufacturing operations, including washing, drying, milling, mixing, calendering, and spreading. Methods of physical testing are also dealt with, and it may be remarked that the author favours the use of "dumb-bell" shaped pieces as recommended by the Bureau of Standards instead of the ring form which, although still excluded by the specification of some consumers, is the type more usually adopted in this country.

There is provided an excellent bibliography containing no fewer than 501 references, many of which are taken from unfamiliar sources; these are arranged according to the names of the authors and are also included in the general index under the appropriate subject heading. A comparison of the text with the bibliography suggests that the book is in no sense intended as a comprehensive treatise on rubber analysis, but it may be regarded as an exposition of the analytical processes favoured by the author. Mr. Tuttle, indeed, writes throughout as one wholly conversant with the methods he is describing, and it is by reason of the critical manner in which these are discussed that the book will appeal most strongly to the rubber technologist.

The style of the book is, on the whole, remarkably clear and incisive, but there are occasional lapses into colloquialism which are apt to be somewhat irritating; thus, we read (p. 70), "if we assume that . . . , we may get a fair line on the quantity of vegetable oils." There are, also, occasional evidences of hurried writing as (p. 40) "when formaldehyde combines with ammonia, instead of following the usual procedure, we get hexamethylenetetramine," or (p. 103) "When zinc oxide or sulphide are present."

Temperatures are quoted thus: 150 C., the sign for degrees being omitted throughout. The heading of some of the sub-sections might, with advantage, be altered. Thus, on p. 34, under "Tests for Cottonseed Oil" in Clarendon type, sub-sections with italicised titles are included which have no reference to the main heading; similarly, on p. 37, sulphur chloride is described under "Tests for Sulphur."

In spite of these minor faults, the book may well be said to have fulfilled its purpose as one of the American Chemical Society's monograph series, namely, "to co-ordinate and present in a concise, readable form" the facts relating to the subject dealt with. B. D. W. Luff.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The general tone gives promise of continued improvement in the chemical trade in spite of the unsettled state of foreign politics. Reports from the textile areas are various and conflicting, but an impartial view leads one to the conclusion that the future is not looked upon as showing any great change for some time. The comparatively small improvements shown during the last few months are fully maintained :—

Acetic Acid, 40% tech., at about £21. Price has a tendency to rise further. Position maintained and satisfactory under present trade conditions. Foreign supplies are in somewhat short supply.

Acid Hydrochloric, 4s. to 5s. carboy delivered. No change in demand.

Acid Sulphuric, average national price for crude tower acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations. The demand for Sulphuric Acid is gradually improving.

Ammonia Alkali, unchanged at about £8. Demand continues good. Home trade improving slightly.

Arsenic (White), £65-£75, shortage continues, although inquiries are not so numerous.

Bleaching Powder, £10 10s. to £11 10s. Slightly better inquiry at present, compared with other heavy chemicals much below normal.

Calcium Chloride, £6. Poor inquiry with continental make offered at lower figures.

Copper Sulphate, about £26 f.o.b., quite nominal.

Potash Caustic, £29 10s. to £30. Slightly better but very poor demand.

Salammoniac. Slight improvement with prices maintained.

Salt Cake, about £5 to £5 10s. Not much business passing. Manufacturers are not offering very freely and seem to anticipate a still further rise in prices as a result of increased demand.

Soda Caustic, 76%, £20 to £21. Home trade or export—position remains firm.

Soda Crystals.—£5 10s., carriage paid. No change.

Sodium Bicarbonate, £10 10s., carriage paid. No change.

Sodium Bisulphite Powder, 60-62%, £19 to £20 10s. per ton, according to quantity, f.o.b. or f.o.r. London, 1 cwt. drums included.

Sodium Chlorate, in slightly improved request. Foreign parcels offered at low prices.

Sodium Sulphide, solid at £16. Not much in demand. Keen foreign competition.

Sodium Sulphite, Pea Crystals, £17 to £17 10s., 1cwt. wooden kegs included.

Bisulphite of Lime, £7 per ton, packages extra and returnable.

Sodium Acetate, 97-98%, £23 per ton.

WOOD DISTILLATION PRODUCTS

There are no changes to report in this section. Manufacturers' prices are as follows :—

Acetate of Lime brown ..	£8 per ton delivered
Acetate of Lime grey 80%	£14 10s. per ton delivered
Acetate of Lime Liquor ..	9d. per gal. 32° Tw. d/d.
Charcoal	£9 10s. to £10 per ton
Iron Liquor	1s. 6d. per gall. 32° Tw.
,, ,, ...	1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14-15° Tw.
Wood Creosote	2s. 6d. ,, ,, Unrefined
Wood Naphtha, Miscible ..	7s. ,, ,, 60% O.P.
Wood Naphtha, Solvent ..	5s. ,, ,, 40% O.P.
Wood Tar	£4 10s. per ton delivered
Brown Sugar of Lead ..	£36 per ton

TAR PRODUCTS

Acid Carbolic Crude 60's ..	2s. 5d. to 2s. 6½d. Numerous inquiries and market strong
Acid Cresylic, 97-99 ..	2s. 2d. to 2s. 3d. Plenty of inquiry.
Acid Cresylic, Pale, 95%	2s.
Acid Cresylic, Dark ..	1s. 10d.
Anthracene Paste, 40% ..	7d. per unit per cwt. Price nominal — no business being done.
Anthracene Oil, strained ..	8¼d. to 10d., small inquiry.
Anthracene Oil, unstrained	7½d.
Benzole, Crude, 65's ..	1s. 0½d. to 1s. 2d.
Benzole, Standard Motor ..	1s. 9d. to 2s.
Benzole, Pure	2s. to 2s. 2d. No inquiry.
Toluole, 90%	1s. 10d. to 1s. 11½d. Small inquiry.
Xylol	3s. to 3s. 6d.
Creosote Cresylic, 20-24%	10d. Fair inquiries.
Creosote, standard specification	7d. to 8d. Demand very good.
Naphtha, Crude	9d.
Naphtha, Solvent 90-160 ..	1s. 9½d. to 1s. 10d. Fair business doing.
Naphtha, Solvent 90-190 ..	1s. 7d. to 1s. 7½d. Not much doing.
Naphthalene, Crude .. Drained Creosote Salts.	£5 to £6 10s. per ton with good demand and firm market.
Naphthalene, Crude, Whizzed or hot pressed	£8 to £10 per ton. Still receiving inquiries and market firm.
Pitch, Medium soft ..	130s. to 140s., market very strong. Prices are at the highest point for months past.
Pyridine, 90-140	11s. to 12s.
Pyridine, Heavy	8s. 6d. to 9s. No business at present.

INTERMEDIATES AND DYES

Business in Aniline Dyestuffs has been quite good during the past week. Prospects have so much improved that some makers are reported to be increasing their staffs. Prices remain unaltered. The chief intermediates are quoted below, carriage paid and packages included unless otherwise stated :—

Acid H.	5s. 3d. lb., 100% basis.
Acid Naphthionic	2s. 8d. lb., 100% basis.
Acid Neville & Winther ..	6s. lb. 100% basis.
Acid Sulphanilic	1s. 6d. lb. 100% basis.
Aniline Oil	11½d., drums extra.
Aniline Salts	11½d. per lb.
Benzidine Base	6s. 6d., 100% basis.
Dinitrobenzene	1s. 3d. lb.
Diphenylamine	4s. 1d. lb.
α-Naphthol	2s. 9d. lb.
β-Naphthol	1s. 2d. lb.

α-Naphthylamine	1s. 7d. lb.
p-Nitraniline	3s. lb.
Nitrobenzene	8d. lb., drums extra.
Nitronaphthalene	1s. lb.
Naphthionate Soda	2s. 8½d. lb., 100% basis.
Diethylaniline	4s. 6d. lb., packages extra, returnable.
Metanitraniline	5s. 6d. lb.
Para Toluidine	5s. lb.
Para Phenylene Diamine	12s. lb., 100%
Meta ,, ,,	5s. 6d. lb.
Meta Toluylene Diamine	5s. lb.
Dinitrotoluene, 48-50° C.	8d. to 9d.
,, 66-68° C.	1s. 2d. to 1s. 3d. naked makers' works.
β-Naphthylamine	1s. 6d. lb.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

There is but little doubt that owing to the French occupation of the Ruhr prices for most chemicals from Germany will shortly be dearer, and prices here must advance in sympathy.

Acid Acetic 80%	£43 per ton ex wharf.
Acid Acetyl Salicylic	2s. 9d. to 3s. per lb. Unchanged at, but the tendency is for higher prices.
Acid Benzoic	1s. 10d. to 2s. per lb. very firm.
Acid Boric, B.P.	£61 per ton crystals. £65 per ton powder, packaged in 2 cwt. bags. Carriage paid U.K.
Acid Gallic	3s. lb.
Acid Pyrogallic cryst.	5s. 6d. lb.
Acid Salicylic	1s. 5d. to 1s. 6d. lb., very firm owing to increase in price of phenol.
Acid Tannic	3s. 3d. lb.
Acid Tartaric	1s. 2½d. to 1s. 3d. lb. The market continues to be firm with a little more demand. Price unchanged. Raw materials have further increased in cost. Foreign manufacturers have now increased their prices for this product.
Amidol	9s. lb.
Acetanilide	1s. 4d. to 1s. 5d. per lb.
Amidopyrin	12s. 6d. to 13s. lb.
Ammonium Benzoate	2s. 6d. to 3s. per lb., according to quantity.
Ammonium Sulphocyanide, recryst.	2s. 6d. per lb., cheaper qualities are available at 1s. 9d.
Barbitone	11s. 3d., market firmer.
Benzaldehyde free from chlorine	3s. 3d. lb.
Benzonaphthol	5s. per lb., with little demand.
Bismuth Salts	Prices unchanged.
Bromides	Have a firmer tendency. Potassium Salt 7d., Sodium 7½d., Ammonium 8d.
Calcium Lactate	3s. 6d. to 4s. lb. for best quality.
Chloral Hydrate	4s. lb.
Formaldehyde 40%	£90 per ton, much firmer. Supplies scarce.
Guaiacol Carbonate	8s. lb. Neglected.
Hexamine	3s. to 3s. 3d. lb. Still very firm. Supplies from Continent are difficult to get.
Homatropine hydrobromide	30s. per oz.
Hydroquinone	3s. 3d. lb., good demand.
Iron Ammonium Citrate	B.P. 2s. 5d. lb. for cwt. lots.
,, ,, ,,	Green, 3s. 1d. lb. for cwt. lots.
Iron Perchloride	£20 to £25 per ton.
Menthol	39s. 6d. per lb. less 2½% for original cases. Smaller quantities 41s. per lb. nett.
Metol	10s. to 12s. for foreign make with rather higher prices for English product.
Methyl Salicylate	2s. 2d. lb., slightly firmer.
Methyl Sulphonal	12s. 9d. lb.
Paraformaldehyde	3s. lb.
Paraldehyde	1s. 4d. to 1s. 9d. lb., in steady demand.
Phenacetin	5s. lb., with more inquiry.
Phenazone	7s. lb.
Phenolphthalein	5s. 3d. lb., still very firm.
Potassium Ferricyanide	4s. lb.
Potassium Iodide	15s. 8d. lb. for cwt. lots, jars and cases free.
Potassium Metabisulphite	6d. to 8d. lb.
Potassium Permanganate	8d. to 8½d. lb.
Salol	2s. lb.
Silver Nitrate	1s. 10$\frac{3}{16}$d. with metal at 41$\frac{11}{16}$ for 1000 oz. lots.
Silver Proteinate	10s. 9d. to 12s. lb.
Sodium Benzoate	1s. 11d. to 2s. lb. Unchanged.
Sodium Citrate B.P.C.	2s. lb. for 1 cwt. lots.
Sodium Hyposulphite, Photographic	£14 15s. for 4 ton lots.
Sodium Salicylate	1s. 11d. lb. powder, 2s. 1d. lb. crystals. In steady demand.
Sodium Sulphite anhydrous	£27 10s. to £28 10s. ton, according to quantity, f.o.r. London, drums included.
Sodium Sulphite crystals	£17 to £17 10s. per ton, according to quantity, 1 cwt. kegs included.
Thymol	19s. lb. for good white crystals.

PERFUMERY CHEMICALS

Amyl Acetate	2s. 3d.
Amyl Butyrate	8s.
Amyl Salicylate	3s. 3d.
Anethol, melting point 21-22° C.	4s. 6d.
Benzyl Acetate from Chlorine free Benzyl Alcohol	3s. 3d.
Benzyl Alcohol free from Chlorine	3s. 3d.
Benzaldehyde free from Chlorine	3s. 3d.
Benzyl Benzoate, 19·5° C.	3s. 3d.
Cinnamic Aldehyde, 98-100% Natural	14s. 9d.
Citronellol	22s. 6d.

Citral, 100%	10s. 6d.
Ethyl Phthalate	4s. 6d.
Eugenol, 100%	10s. 6d.
Geraniol (from Palmarosa)	32s. 6d.
Geraniol	5s. 6d. to 12s. 6d.
Iso Eugenol	16s.
Linalol ex Bois de Rose ..	21s.
Linalyl Acetate	22s. 6d.
Methyl Benzoate	8s. 6d.
Phenyl Ethyl Acetate ..	10s.
Phenyl Ethyl Alcohol ..	17s. 6d.
Rhodinol	52s. 6d.
Terpineol	3s.

ESSENTIAL OILS

Business generally is inclined to be better. There are more inquiries for export. Home trade may still be called dull.

Almond Oil	12s. 6d. lb. f.o.r. P.A. quality.
Anise Oil, China star ..	2s. 1d. to 2s. 2d. lb. Flat to arrive, can possibly be bought at 1s. 10d. c.i.f.
Bergamot Oil	12s. to 14s. lb., quotations for forward shipments at 11s., 11s. 6d. c.i.f., due to depreciation of the lira.
Bourbon Geranium Oil ..	25s. lb. Very firm.
Camphor Oil	80s. lb. for white in tins and cases.
Cananga Oil, Java ..	8s. to 10s. lb., a quantity of very inferior quality is on the market.
Cinnamon Oil, Leaf ..	5s. 8d. lb. for Ceylon, very quiet.
Cassia Oil, 80-85	8s. 9d. lb. on spot, inclined to be easier.
Citronella Oil, Java ..	3s. 4d. lb., very firm.
Citronella Oil, Ceylon ..	2s. 6d. lb., very firm and higher prices talked.
Clove Oil	6s. 9d. lb. Very firm in harmony with the spice which is an excited market.
Eucalyptus Oil	1s. 6d. to 1s. 7d. lb. Steady.
Lavender Oil, Mont Blanc, 38-40%	14s.
Lemon Oil	2s. 8d. to 2s. 9d. lb., inclined to be easy owing to depreciation of lira.
Lemongrass Oil	2⅝d. oz. Steady.
Orange Oil, sweet	8s. 6d. lb. on spot, forward about the same.
Otto of Rose Oil	20s. to 30s. per oz. A great deal of rubbish on the market.
Palma Rosa Oil	17s. 6d. lb. spot, 16s. forward, c.i.f. for good brands.
Peppermint Oil—	
English	70s. lb. Steady but quiet.
Wayne County	13s. 6d. lb., firm and talked higher, but difficult to find the reason.
Japanese	7s. 9d. spot. Very firm, buyers should hesitate about purchasing large quantities.
Petitgrain Oil	6s. 6d. lb. Flat with practically nothing doing.

TRADE NOTES

The Norwegian Pyrites Industry in 1921

According to an article in *Die Chemische Industrie* (December 27, 1922), 1921 and 1922 were bad years for the Norwegian pyrites industry. The demand declined heavily and the keen competition that ensued led to large reductions in prices. Before the war, Norwegian pyrites, which is mainly exported, had Spanish pyrites as its chief competitor in the world's markets, but since the development of the Frasch process for winning sulphur, the sulphur deposits in Louisiania and Texas have become dangerous rivals. The strength of American competition in Europe is shown by the fact that sulphur has been substituted for pyrites even in certain Norwegian sulphite-pulp factories. Some of the Norwegian mines suffer from the disadvantage that the pyrites contains copper which must be extracted by a process under German control before the roasted ore can be sold. Recently, Norwegian pyrites has been unable to find a market in England, and exports are now restricted to Germany, Sweden, Belgium, and the north of France. Prices have consequently been forced down almost to the pre-war level, although production costs have doubled, and many mines have had to close down. This tells heavily on the country, because pyrites-mining, which is largely in foreign hands, was one of the chief Norwegian industries. The situation is not quite hopeless, however, for the demand will probably increase with improving economic conditions, and in the division of markets due to Spanish-American competition, Norway will probably be left to compete mainly with Spain, where production costs are increasing owing to high wages and a new export duty.

Vol. 42 NEW SERIES LONDON, JANUARY 26, 1923 No. 4

EDITORIAL

THE DISCOVERY of a new element is an event of first-rate interest and importance and the University of Copenhagen and Professors Coster and Hevesy are to be very warmly congratulated on the discovery of the latest addition, Hafnium. This is the first element to be discovered by means of its X-ray spectrum, and the method may easily be fruitful in other directions. There are not many elements yet to be discovered (if modern theories are correct), and two of these are homologues of manganese; a detailed X-ray examination of manganese minerals might reveal something of interest. The Scandinavian minerals seem to be as rich in elements as are their men of science in genius. Chlorine, yttrium, tantalum, cerium, selenium, lithium, thorium, lanthanum, erbium, terbium, scandium, thulium, and possibly oxygen were first discovered by the Scandinavians, and there may be some other instances which we have forgotten.

* * *

We are glad to print a communication from Sir Arthur Colefax, dealing with the decisions of the Referee on the definition of organic compounds. Our columns are, of course, open to him and to Sir William Pope, and any others who care to join in the discussion. *Uno averso non deficit alter.* We, who do not profess any great knowledge either of the chemical or the legal aspect of the discussion, are not sure whether these distinguished champions occupy the same platform; it may be they are appealing to different audiences, the one to an audience which is not accustomed to weigh the definitions of chemistry with that precision which Acts of Parliament are assumed to attain (though in fact these Acts are occasionally imperfect in places), the other to an audience, trained to scientific accuracy, but as Professor Bone has recently said, thrust into this wicked world without knowing the difference between a ten and an ace. The one audience, comprising a fair proportion of the ordinary users of chemical terms, has no clear-cut idea of a definition; it means not, but blunders round about a meaning; the other compensates for what may be its lower numerical strength by its superiority in learning and precision. We are entitled to remind our legislators and the lawyers who interpret their phrases, "how fallacious it is to judge of the nature of things by the ordinary and inconstant use of words."

* * *

Since 1912, when an International Opium Convention was signed at the Hague, many attempts have been made to prevent the growing abuse of habit-forming drugs, such as opium, morphia and cocaine. Some of these attempts have merely resulted in shifting the centres of the drug traffic to uncontrolled regions; and the check on the cultivation of the opium poppy in China has lapsed during the present disturbances, for cultivation of the crop has apparently been resumed over one-tenth of the former area. The Committee of the League of Nations, which is considering methods of controlling the drug traffic, has been unable to collect complete statistics of the amounts of habit-forming drugs actually required for medical and scientific use, but it is certain that the production is far in excess of the quantity required for legitimate purposes. That there is this excess is shown by the fact that hundreds of thousands of pounds of opium and many tons of morphia are produced annually, whereas it is estimated that ten large London hospitals, which treated over 70.000 in-patients, and 550,000 out-patients in 1921, consumed less than 42 lbs. of opium, 5½ lbs. of morphia, and a little over 9 lbs. of cocaine, during the year. It is therefore to be anticipated that the inquiry by the League of Nations will lead to the enactment of more stringent regulations. Unfortunately, the existence of the drug evil is very real; attempts to suppress it cannot but meet with approval. But Regulations such as those issued under the Dangerous Drugs Act in 1921, however laudable may be their intent, cannot be approved when they restrict scientific research even slightly, by preventing the genuine research worker from obtaining, without delay, reasonable quantities of the drugs in question, which are in constant use in chemical, physiological, pharmacological and other laboratories. It therefore behoves all chemists to unite so that when more stringent Regulations are issued, they may be able successfully to insist on modifications that will safeguard the interests of research without prejudice to measures designed to protect the unfortunate people who are addicted to the drug habit.

* * *

We are glad to find that Viscount Leverhulme's suggestion, that the human element in chemistry and industry should receive special attention, is already being acted upon. We have received—although too late to insert in this week's issue—an interesting communication from the genial Secretary of the Chemical Employers' Federation, and we hope that we shall be favoured by some communications dealing with the chemical industry from the point of view of the great labour organisations. No one can easily look at a problem from someone else's point of view. Even with the aid of Einstein's conception, whereby every straight line is curved, we cannot persuade our brains to show facts in the perspective which is at once apparent to our friend across the table. This is very noticeable in the grave international complications which now confront us. Some of our newspapers are able to look at this threatening position from the point of view of this country in relation to Germany, others have put forward the appearance which we imagine is visible to the Germans in relation to the world at large, but how difficult it is for us to see the problem as between France and Germany. Every chemist knows that prolonged friction produces heat. This is the cause of international troubles, of strikes and many other disagreeable events. The free ventilation of grievances before they become too acute to be borne is the best remedy and we hope that our columns, by no means large, will yet be wide enough to welcome a frank expression of opinion on all those affairs which interest us as a chemical community. We appeal to all those who have special knowledge of, or experience in the human side of industry to give the chemical public in all the English-speaking communities the benefit of their views, and to send us their impressions in order that we may duly publish them. There are some interesting developments in co-partnership, insurance, profit-sharing, and so on, which have received scant notice in scientific and technical publications; and as we have a large circulation outside Great Britain, an account of these might be of considerable interest.

AN ATTEMPT TO RESOLVE QUATERNARY PHOSPHONIUM COMPOUNDS

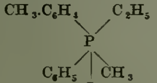
L. G. RADCLIFFE, M.Sc.,Tech., F.I.C. AND
W. H. BRINDLEY, B.A., M.Sc.Tech.

ALTHOUGH the history of stereoisomerism covers but a few years this study now holds not only an exalted, but a revered place in the annals of chemistry. That a large measure of credit must be assigned to Pasteur for the creation of this branch of chemistry can scarcely be questioned, for although the subject was not placed on a really satisfactory basis until Van't Hoff and Le Bel independently enunciated their theory in 1874, it is to Pasteur that we are indebted for opening before us so fruitful a source of investigation. A perusal of the literature shows that the period between 1860 and 1874 is, comparatively speaking, a barren one in the field of stereochemical research. This study required a fresh impetus and that was given by the Van't Hoff-Le Bel hypothesis. A brief survey of the past history of stereochemistry will at once reveal the fact that science owes a debt of gratitude to the discoverers of optically active compounds; the monumental researches of Ladenburg and Emil Fischer were made possible by the genius of the founder of stereochemical theory.

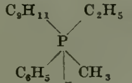
Whilst the name of Le Bel is perhaps best remembered by his publications of 1874, it must not be forgotten that he was the first to show that carbon was not the only elementary body possessing what has been aptly termed "the seal of noblesse," i.e., optical activity. The year 1891 stands out in bold relief in the history of this branch of chemistry, for it is the year in which a nitrogen compound of the type abcdNX was first resolved into its optically active isomerides; the compound in question being methylethylpropylisobutylammonium chloride (*Compt. rend.*, 1891, **112**, 724). The result of this investigation demonstrates very clearly how a problem which one worker finds little difficulty in solving becomes an impossibility in the hands of a subsequent investigator, for Marckwald and von Droste-Huelshoff (*Ber.*, 1899, **32**, 560), failed to confirm the results obtained by Le Bel, whilst Pope and Read (*Trans.*, 1912, **101**, 519) showed that Le Bel could not have had in his hands the nitrogen derivative he supposed he had resolved. Wedekind (*Ber.*, 1899, **32**, 517) attempted a resolution of *a*-benzylphenylallylmethylammonium hydroxide, but was also unsuccessful. Pope and Peachey (*Trans.*, 1899, **75**, 1127), on the other hand, resolved a tetralkyl-ammonium salt, *a*-benzylphenylallylmethylammonium iodide, and arrived at the conclusion that the failures recorded by previous workers were due to the fact that they had neglected to recognise the possibility of such a body being decomposed by dissociating solvents into the tertiary base and alcohol. This research by Pope and Peachey led to much new work in the field of stereochemistry, and the time was near when the atoms of various elements, other than carbon and nitrogen, would be found to act as centres of optical activity.

ASYMMETRIC PHOSPHORUS COMPOUNDS

The earliest available information connected with this particular type of research emanated from the laboratory of Michaelis (*Annalen*, 1901, **315**, 54). In this publication he describes the preparation of quaternary phosphonium compounds of the type :—$P.R_1.R_2.R_3.R_4$.Halogen, and he obtained (1) *p*-tolylphenylethylmethylphosphonium iodide, and (2) *pseudo*-cumylphenylethylmethylphosphonium iodide.



(1)



(2)

These asymmetric bodies he attempted to resolve, in the first place, by means of optically active acids, but found that crystalline salts could not be obtained ; he was likewise unsuccessful in effecting a cleavage by means of micro-organisms, and pointed out that the phosphonium compounds appear to have a "restraining influence" on the organisms.

In the following year Caven (*Trans.*, 1902, **81**, 1362) showed that the configuration of the phosphorylchloride molecule is tetrahedral, that compounds of the type :—

$$O{:}P\begin{cases}R_1\\R_2\\R_3\end{cases}$$

do not contain a plane of symmetry, and that, notwithstanding the double linkage, they are asymmetric. Caven pointed out that on theoretical grounds it should therefore be possible to prepare optically active derivatives of phosphoryl chloride, a prophecy which was fulfilled a few years later. At that time all recorded instances of optical activity of compounds showed that this property was due to the presence of one or more fully saturated asymmetric groups, and in no case had it been shown that this phenomenon depended on the presence of an unsaturated complex in the molecule. The first instance of the splitting of such a compound was recorded by Meisenheimer (*Ber.*, 1908, **41**, 3966); this was a nitrogen compound of the type abcN:X, namely, methylethylaniline oxide. Following closely upon this successful effort Luff and Kipping (*Trans.*, 1909, **95**, 1993), and Kipping and Challenger (*Trans.*, 1911, **99**, 626) investigated phosphorus compounds of the type :—

$$O{:}P\begin{cases}OR_1\\OR_2\\OH\end{cases}$$

with a view to their resolution. Although they were not completely successful it would seem that an externally compensated mixture was present. The preparation in the free state of the optically active components was not found practicable owing to the stability of their salts.

When Meisenheimer succeeded in resolving the doubly-linked nitrogen compound he turned his attention to the closely related phosphine oxides, and was again successful in effecting a resolution. In conjunction with Lichtenstadt (*Ber.*, 1911, **44**, 356), he prepared methylethylphenylphosphine oxide, and carried out the resolution by means of *d*-bromocamphorsulphonic acid. The following year records two attempts to resolve phosphorus compounds of the type $P.R_1.R_2.R_3.R_4$.Halogen. Pope and Gibson (*Trans.*, 1912, **101**, 735) prepared :—(1) phenyl - *p* - tolylmethylallylphosphonium iodide, and (2) phenyl-*p*-tolylbenzylmethylphosphonium bromide. Attempts to resolve the iodide by means of optically active acids resulted in viscid residues which could not be crystallised. Crystallisation of the bromide was effected, but no evidence of a resolution was obtained. The publication of this work caused Wedekind (*Ber.*, 1912, **45**, 2933) to announce the results of a similar investigation in which he successfully crystallised the body phenyl- *p*- tolylethylmethylphosphonium - *d* - camphorsulphonate, which, when examined polarimetrically, gave :—

$$[\alpha]_D = +21{\cdot}9° \text{ and } [M]_D = +103{\cdot}85°.$$

From these readings Wedekind assumed that he had been successful in bringing about a fission of the quaternary phosphonium base, this assumption being based on the fact that the molecular rotation of the *d*-camphorsulphonic ions amounts to +51·7°. Had he regenerated the base and found it active then, there would have been more concrete evidence that a cleavage had been obtained. It is evident that owing to lack of material he was unable to carry this investigation to a really satisfactory conclusion. In the meantime it has been generally accepted that a resolution of asymmetric phosphorus compounds of this type has not been effected.

In the present work the compound *p*-tolylphenylmethylallylphosphonium iodide, first prepared by Pope and Gibson (*loc. cit.*), was obtained, but whereas in the Pope and Gibson synthesis phosphenyl chloride was the initial stage, in this work *p*-tolylphosphine dichloride was employed.

EXPERIMENTAL

p-Tolylphosphine dichloride, $CH_3.C_6H_4.PCl_2$.—This body is obtained by heating a mixture of toluene and phosphorus trichloride in the presence of freshly prepared aluminium chloride (Michaelis, *Annalen*, 1882, **212**, 203).

$$C_6H_5.CH_3+PCl_3=CH_3.C_6H_4.PCl_2+HCl$$

Considerable difficulty is experienced in obtaining this substance in a perfectly pure state ; only after fractionating several times and freezing the resulting oil out of contact with air can the impurities be removed. The yield is unsatisfactory, for under the most favourable conditions it rarely exceeds 10 per cent. of the theoretical.

p-Tolylphenylchlorophosphine,

$$\begin{matrix}CH_3.C_6H_4\\ C_6H_5\end{matrix}\!\!>PCl$$

The preparation of this compound was, in the main, carried out on the lines suggested by Michaelis (*Annalen*, 1901, **315**, 59), that is, by heating the primary chlorophosphine, *p*-tolylphosphine dichloride, in excess with mercury diphenyl.

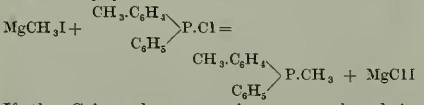
$$2(C_6H_4Me)PCl_2+(C_6H_5)_2\ Hg=2(C_6H_4Me)\ (C_6H_5)PCl +HgCl_2$$

To isolate the *p*-tolylphenylchlorophosphine the brown, resinous mass was refluxed several times with water-free benzene, the solution filtered through kieselguhr and distilled in an atmosphere of carbon dioxide.

p-Tolylphenylmethylphosphine,

$$\begin{matrix}CH_3.C_6H_4\\ C_6H_5\end{matrix}\!\!>P.CH_3$$

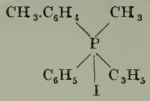
In preparing the tertiary phosphine the Grignard reagent was employed in preference to a zinc alkyl and this method gave good results, though only by using a very considerable excess of magnesium methyl iodide could satisfactory yields be obtained.



$$MgCH_3I+\begin{matrix}CH_3.C_6H_4\\ C_6H_5\end{matrix}\!\!>P.Cl=\begin{matrix}CH_3.C_6H_4\\ C_6H_5\end{matrix}\!\!>P.CH_3 + MgClI$$

If the Grignard reagent is not employed in large excess there results a jelly-like mass from which the tertiary phosphine is removed with difficulty; the best yields were obtained by using 4 molecular proportions of Grignard reagent to 1 of secondary chlorophosphine.

p-Tolylphenylmethylallylphosphonium iodide



This body was obtained by treating an ethereal solution of the tertiary phosphine with an ethereal solution of freshly-distilled allyl iodide. On mixing these ethereal solutions turbidity ensued, and after standing for a short time there resulted a small quantity of oil. The ether was removed, the oil dissolved in the least quantity of absolute alcohol and anhydrous ether added until there was a pronounced turbidity. On standing for some time the quaternary phosphonium iodide was precipitated in the form of fine crystals.

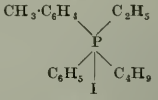
It became evident that a very small proportion of the iodide had been precipitated in the crystalline state, and it was decided to examine the alcohol-ether solution. On distilling there remained a viscous oil which could not be induced to crystallise, so that the yield was far from satisfactory. The crude *p*-tolylphenylmethylallylphosphonium iodide was recrystallised from alcohol, and was obtained in the form of small, colourless, glistening needles, which, on exposure to light, become yellow. It melts at 175° with decomposition.

0·1896 gramme gave 0·1162 gramme AgI
C_{17} H_{20}PI calculated I 33·24
" found I 33·12

p-Tolylphenylmethylallylphosphonium - d - bromocamphorsulphonate

The quaternary phosphonium iodide was treated with an equivalent quantity of the silver salt of *d*-bromocamphor-sulphonic acid dissolved in dilute alcohol. The precipitated silver iodide was filtered off, the filtrate evaporated to low bulk and placed in a vacuum desiccator. After standing for some weeks a jelly-like mass resulted, but no indication of crystallisation was observed; eventually the compound assumed the condition of a resin.

p-Tolylphenylethyl - n - butylphosphonium iodide



On mixing ethereal solutions of *p*-tolylphenylethylphosphine and *n*-butyl iodide there was no apparent change, a marked contrast to the result obtained in preparing *p*-tolylphenylmethylallylphosphonium iodide. In the hope of bringing about more perfect combination the mixture was warmed for some time, allowed to cool, and anhydrous ether added. Eventually there was obtained an oily precipitate, but this could not be crystallised. A similar failure has to be recorded for *p*-tolylphenylethyl - *n* - propylphosphonium iodide.

CONCLUSION

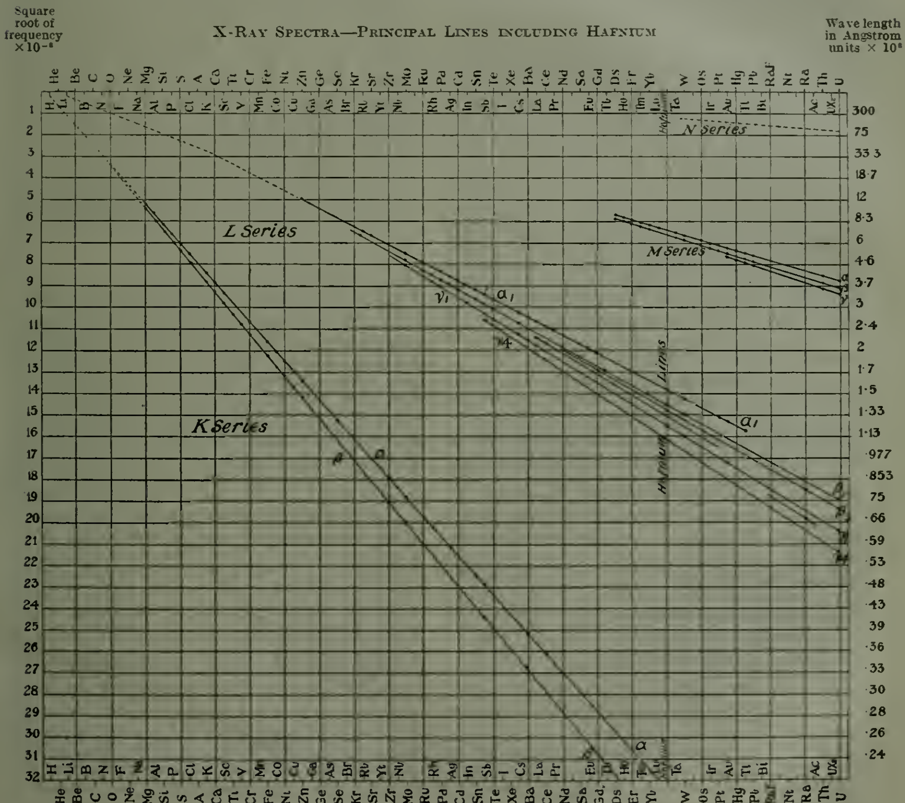
Whilst the original idea of proving that the completely asymmetric phosphonium base, $P.R_1.R_2.R_3.R_4.OH$, exists in optically active forms has not been realised, it is felt that the results obtained should be recorded. The outstanding difficulty was the creation of a sufficient amount of material, the poor yields preventing one from making an extended study of the fission problem. It is felt that the choice of compounds is somewhat limited, since it does not appear to be convenient that the last group introduced shall be other than methyl, allyl, or benzyl. Thomas and Jones (*Trans.*, 1906, **89**. 280) pointed out that the iodides of the above radicles are the only ones, as a rule, which react extensively with tertiary amines containing aromatic and other large alkyl groups. Perhaps the difficulty of introducing the butyl and propyl radicles is analogous to the stereochemical obstruction noticed in the case of tertiary amines.

Municipal College of Technology,
Manchester.

THE NEW ELEMENT HAFNIUM

Professors Coster and Hevesy of Copenhagen announce in *Nature* of the 20th inst. the discovery of a new element which they call Hafnium, after Hafniae, an ancient name for Copenhagen. The new element is homologous to zirconium and is apparently present in specimens of zirconium minerals to the extent of possibly one per cent. It has been discovered by means of its X-ray spectrum and the diagram we print above shows how the principal lines of the X-ray spectra of the elements fit into a scheme which enables any element, whether known or unknown, to be identified by its X-ray spectrum. The lines of Hafnium which have been measured are: $L\alpha_1=1565$, $\alpha_2=1576$, $\beta_1=1371$, $\beta_2=1323$, $\beta_3=1350$, $\gamma_1=1177$ X. u. Our diagram, necessarily very hurriedly prepared, shows the wave lengths in units which are a thousand times larger than the X-units used by the discoverers of the new element.

The University of Copenhagen has taken a very important place of recent years in both Chemistry and Physics; the theories of Professor Bohr as to the structure of the atom and the calculations he has made of the orbits of the revolving electrons are known all over the world and seem to have provided a clue to unravel the difficulties of the emission of ordinary bright-line spectra. The output of accurate determinations of X-ray spectra by Professors Hjalmar, Coster and others has been considerable, and these workers and their French colleagues, Professors Urbain, de Broglie and Dauvillier, have now made nearly a complete survey of this interesting field of research. The claims of Urbain and Dauvillier to fill the space belonging to the atomic number 72, with a rare earth element celtium, must be borne in mind, and we hope to be able to publish a full account of the subject at a later date.



X-Ray Spectra—Principal Lines including Hafnium

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

THE TROUBLE IN THE RUHR

is causing anxious thought to those engaged in the chemical industry, and in particular, to manufacturers of dyestuffs and fine chemicals. I have spoken to many of our leading authorities during the past week, and not one of them seems able to tell me what is likely to happen in that unfortunate part of the Continent. At the moment of writing it seems clear that the economic pressure of France is to be met by the passive resistance of the Germans. How the affair will end the event alone will show, but it will not be in comedy. It is not the way of the French. The Anglo-Saxon may hesitate, compromise, and decline to co-operate and employ gestures of friendship. The French, however, are careful above all, of their national dignity, and when committed to an enterprise do not care to draw back. So the die is cast, and the play must be played out to the bitter end. The end we cannot foresee, but one or two results appear to be inevitable.

GERMANY CANNOT CONTINUE

to purchase the chemical raw materials which she has been in the habit of obtaining from us. Those heads of Universities and Schools who have obtained their research chemicals and their glassware from Germany may find themselves once more having to rely on British makers. Then there is the question of dyestuffs. It would be too unkind if, just after the Manchester Chamber of Commerce had decided that the Dyestuffs Act must go, the colour users of Lancashire and Yorkshire found themselves glad to use products of their own country. And what about Reparations ? At the present time I am told we are taking quite a substantial quantity of German dyestuffs under the provisions of the Treaty of Versailles. Will this continue ? It is a nice problem. Suppose the Germans decline to give any of the Allies the dyestuffs demanded, or, worse still, suppose they agree to furnish England with her quota but no other Ally. Is England compelled to share her quota with the other Allies ? Nobody knows, but the position opens up a very interesting speculation.

THE EDITOR'S FOOT-NOTE

to my paragraph last week, on the British Empire Exhibition betrays that prescience which is so essential to an editor. (This will not secure more space for our contributor—Editor, C. and I.) I now hear that there is to be a meeting of the representatives of the chemical societies this week, at which it is hoped a plan will be devised for a really comprehensive exhibit illustrating the progress made during recent years. It seems to me this exhibit should answer a question which will be in the minds of many visitors from abroad, who will look at the Chemical Section with critical eyes. They will see the progress which chemical industry has made, but what they will endeavour to estimate is whether we have behind it all a stream of new inventions flowing from the research workers in our Universities and Colleges, and in the laboratories of the chemical manufacturers themselves. That will be the question which will have to be answered, for on its answer there largely depends the attitude which our competitors will adopt towards us. I therefore greatly hope our scientific leaders will seize a unique opportunity of impressing the world at large that in this matter Britain maintains, and even surpasses, the honourable reputation she has so long enjoyed. And I am fully convinced that they will take this opportunity and provide us with an interesting and convincing exhibit, shewing the recent achievements in pure chemistry in this country.

THE "SCIENTIFIC AMERICAN"

is among the papers which I regularly read—I think I remarked before that my reading is wide rather than deep—and it set me wondering about recent discoveries. I wondered what was the ontstanding discovery in chemistry or physics of the past decade. I hear my friends talk of Rutherford's prowess in smashing the atom and of Professor Morgan's ingenuity in turning Tellurium to new uses, and a host of other pieces of great original work by men with equally well-known names. In America work of this character is immediately communicated to the thinking public in a most readable form, and the public is thereby educated. Nothing of the sort, as far as I know, is ever attempted in this country, and yet I am convinced there is a large number of intelligent members of the public who have received the rudiments of a scientific education who would be only too ready to avail themselves of such a publication. One has only to think of the number of amateurs who know a great deal about motor cars and wireless apparatus to realise this. I suppose the trouble is that it is difficult for some of our most learned scientists to express themselves in sufficiently simple language to be understood by the people. I hope they will try. As an old journalist I know how difficult it is to prepare a weekly journal which will be palatable to both experts and the general public, but whether we are Fellows of the Royal Society, or merely humble hewers of cellulose and drawers of hydrone, we like to know the new inventions which are coming along. In the meantime, which is the outstanding discovery of the past decade ? Will some of my readers tell me, please ?

FORTHCOMING EVENTS

Jan. 29. Society of Chemical Industry, *Yorkshire Section*, the Queen's Hotel (Room 100), Leeds, at 7.15 p.m. "The Colour Measurement of Brown Solutions," by H. R. Proctor, D.Sc. "Note on the Separation of Propionic Acid from Pyroligneous Acid," by G. W. Douglas.

Jan. 31. University of London, University College, Gower Street, W.C. 1, at 5 p.m. "Radioactivity and X-Rays," by Professor Sir William Bragg, K.B.E., F.R.S.

Jan. 31. Royal Society of Arts, 18, John Street, W.C. 2, at 8 p.m. "The Relation Between Chemical and Antiseptic Action in the Coal-Tar Dyes," by Thomas H. Fairbrother, M.Sc., F.I.C., and Arnold Renshaw, M.D., D.P.H.

Feb. 1. Society of Chemical Industry, *Bristol Section*, Chemical Dept., The University, Woodland Road, Bristol, at 7.30 p.m. "The Necessity for a Change in the Milk Standard," by Edward Russell.

Feb. 1. Silvanus Thompson Memorial Lecture, Technical College, Leonard Street, E.C. 2, at 7.30 p.m. "The Basis of Wireless Communication," by Sir Oliver Lodge, F.R.S. To be followed by a Conversazione and Reunion of Old Students.

Feb. 1. The Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 3 p.m. "Photo-synthesis of Plant Products," by Prof. I. M. Heilbron.

Feb. 2. The Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 9 p.m. "Fact and Phantasy in Industrial Science," by C. F. Cross, F.R.S.

Feb. 2. Society of Chemical Industry, *Manchester Section*, Textile Institute, 16, St. Mary's Parsonage, Manchester, at 7 p.m. "A New Process for the Manufacture of Sodium Thiosulphate," by Luke Hargreaves, Esq., and Dr. A. C. Dunningham. "Considerations Relating to the Choice of Materials for Stone Dusting of Mines, with special reference to Carbonate of Lime," by A. C. Dunningham, D.Sc. "Some Developments in Gas Producers," by T. Roland Wollaston, M.I.M.E.

Feb. 5. Society of Chemical Industry, *London Section*, Engineers' Club, Coventry Street, W., at 8 p.m. "The Estimation of Fat in Casein," by G. T. Bray and F. Major. "Explosions in Liquid Air Rectification Plant," by Dr. E. Fyleman.

NEWS FROM THE SECTIONS

SOUTH WALES SECTION

By the courtesy of the Directors of the Anglo-Persian Oil Co., Ltd., members of the South Wales Section had the unique opportunity of inspecting the new National Oil Refineries at Llandarcy, near Skewen, on January 13. About forty members assembled at the works at 10.45 a.m. and were conducted round the works by Dr. Thompson (chief chemist) and Mr. Wrench. In turn the members visited the offices, the laboratory and the boiler house, in which automatic coal-firing and oil fuel are used.; the power house was then inspected, followed by the plant for distilling crude oil, the bauxite filters, the compressor house (in which by-products are extracted), the experimental laboratory, and the benzine refinery and rectification plant.

The party was afterwards entertained to lunch on the premises, and Mr. W. R. Bird proposed and Mr. J. H. Wells seconded a hearty vote of thanks to the Directors for their permission for the visit and to Dr. Thompson and Mr. Wrench, who had so fully explained the various plants and operations to the members.

LIVERPOOL SECTION

A paper on the "Manufacture of Patent Fuels" was read by Mr. A. Grounds, B.Sc., at the meeting held on January 19. The centre of the briquetting industry in Great Britain is in South Wales, the main works being situated in Cardiff, Swansea, Newport, and Llanelly. Roughly 3 million tons of patent fuels is produced annually by these works, so that the magnitude of the industry will be realised. The choice of coals for briquetting depends on the ultimate destination of the fuel and the purpose for which it is to be used. For domestic fuel, the coal blend consists chiefly of anthracite with a little bituminous coal (usually about 10 per cent.), and about 10 per cent. of medium soft coal-tar pitch. The bituminous coal is added so that when the pitch has burnt off on igniting the fuel, the fine anthracite duff does not fall to powder in the grate but is bound together by the bituminous coal, which must, of course, be of the caking variety. For fuel intended for steam raising, the coals used are generally those from the "steam coal" seams, with the admixture of anthracite and bituminous coal in proportions to correspond to any desired specification. Briquettes intended for use in boilers may vary in size from a small 2 lb. block to one weighing about 28 lb. The 28 lb. block was originally made because it corresponded to the weight which could be carried by a native coolie. The largest consumers of British patent fuel are France, Italy, Switzerland, Egypt and the Scandinavian countries.

Careful control of manufacture is essential since the cost of the pitch used to bind the fuel together is so high. With pitch at its present price of about £7 per ton, the cost of pitch alone in a ton of briquettes amounts to 14s., so that with the cost of the raw coal, labour, establishment charges, etc., very little margin is left for profit, and it is really doubtful at the present time whether patent fuel can be made profitably. Other binders have been sought for during the last forty or fifty years, but no material has been found which is a completely satisfactory substitute for pitch. The materials proposed have been either too dear or too scarce to be seriously considered. Research is required in order to solve this problem and numerous others which have arisen. Thus, there is a prejudice against briquettes or ovoids for domestic fuel consumption because the extremely light and flocculent ash which remains when the fire has gone out gives rise to dust and causes extra work for the housewife. Probably this problem could be successfully solved by adding some easily fusible material to the coal in quite small proportions in order to render the ash fusible, so that after a fire had burnt out, the ash would not be powdery but in the form of clinker which could be removed without creating dust. In steam-raising practice, clinkering is a serious problem, and since more bituminous coal is used in the manufacture of the type of fuel used for this purpose, the ash tends to form clinker more easily than that from the domestic type of patent fuel. Careful blending is essential in order to secure a non-fusible or difficultly fusible ash, and the ash of the coals in regular use should be examined. No systematic research has ever been carried out in this country on the chemical side of briquette production.

Briquettes are usually compressed under a pressure of the order of 30 cwt. to 2 tons per sq. in., but it has been found possible to briquette coal without adding a binder by increasing the pressure up to 10 to 12 tons per sq. in. This process has been carried out by Pure Coal Briquettes, Ltd., and the results have been described by E. R. Sutcliffe and E. C. Evans in a paper read before the London Section of this Society (*cf.* J., 1922, 196 T). The circular briquettes made by this process have the appearance of a piece of finely turned and polished ebony. Very fine grinding is essential, and only certain coals can be treated by this process. Coals with a low content of volatile matter have to be blended with coals containing a higher percentage of volatile matter. A new process has been devised by Minerals Separation, Ltd., in conjunction with the Powell Duffryn Collieries, in which the coal is washed by the froth-flotation process, simultaneously coated with the requisite quantity of binding agent, and then pressed direct. Excellent briquettes are said to have been obtained, and the water from the flotation cells is eliminated without any trouble.

EDINBURGH AND EAST OF SCOTLAND SECTION

The annual dinner of the Edinburgh and East of Scotland Sections of the Institute of Chemistry and the Society of Chemical Industry was held in the Royal Hotel, Edinburgh, on January 20.

Dr. H. E. Watt, chairman of the local Section of the Society of Chemical Industry, presided over an attendance of about 50 members, and the guests included the President and Secretary of the Society of Chemical Industry, the President and Registrar of the Institute of Chemistry, Sir James Walker, President of the Chemical Society, and Lady Walker. Apologies for absence were intimated from Lord Provost Hutchison and Mrs. Hutchison, Principal Sir J. Alfred Ewing and Lady Ewing, and Dr. T. R. Duggan, of New York.

The toast of "Chemistry and Industry" was proposed by Mr. R. B. Pilcher, and replied to by Mr. A. Chaston Chapman and Dr. E. F. Armstrong. Dr. L. Dobbin, chairman of the local Section of the Institute of Chemistry, proposed the toast of "The Guests," which was responded to by Dr. J. P. Longstaff. An excellent musical programme was rendered by various members of the local Sections, and an enjoyable evening closed with the toast of "The Chairman," proposed by Dr. T. W. Drinkwater.

MONTREAL SECTION

Les membres de la section montréalaise de la "Society of Chemical Industry," apres avoir été les hôtes de la "Société de Chimie industrielle de France" (succursale de Montréal), au café Kerhulu, se sont réunis le 12 décembre à l'Ecole Polytechnique. Des discours furent prononcés en anglais et an français. Au nombre des hôtes d'honneur au dîner, on distinguait S. G. Mgr. Georges Gauthier, recteur de l'Université de Montréal et M. Paul-E. Naggiar, consul général de France. La santé "aux hôtes de la soirée" fut proposée par M. W.-B. Woodland, qui parla en français. Mgr. G. Gauthier y répondit en anglais, et M. Naggiar, en français.

Il y eut en suite une séance au cours de laquelle on présenta des travaux scientifiques. M. LeCointe présenta une étude sur une méthode rapide d'estimation du gras dans la crème glacée ; M. le professeur L. Bourgoin lut un travail très intéressant sur l'action catalytique des rayons ultra-violet ; puis M. le professeur J. Flahaut lut une étude sur la chimie physique et la formation des ingénieurs chimistes. Ces diverses études furent écoutées avec intérêt et fort applaudies.

Uu concert de radio, dirigé par M. le professeur Villeneuve, fut très apprécié. M. le consul général de France au Canada avait bien voulu mettre à la disposition des professeurs de l'Ecole Polytechnique un film instructif illustrant la fabrication de la porcelaine de Sèvres. Les diverses vues qui se déroulèrent sur l'écran permirent aux spectateurs de se renseigner sur l'une des plus intéressantes industries de France.

La réunion se termina par un échange de compliments entre chimistes de langue anglaise et chimistes de langue française, tout joyeux de contribuer ainsi à promouvoir la belle cause de la bonne entente entre les cercles qui s'occupent de chimie industrielle.

MEETINGS OF OTHER SOCIETIES

THE FARADAY SOCIETY

On January 15 a meeting was held in Burlington House, the President, Sir R. Robertson, occupying the chair, and Mr. E. W. J. Mardles presented four papers dealing with the physical properties of non-aqueous systems of sols and gels.

Mr. Mardles' first paper, entitled "The study of the reversible sol to gel transition in non-aqueous systems," was divided into two parts. The work in all four papers was carried out with different concentrations of cellulose acetate in benzyl alcohol, which produces no disturbing chemical change. In the first part, on the change in viscosity with time, the results of observations made using the Ostwald capillary tube pattern, the falling sphere, and rotating cylinder and disc types of viscometers, were given, and it was stated that the shapes of the viscosity-time curves obtained depended upon the methods by which the viscosity was measured. During gelation, the sols being a heterogeneous system, the viscosity readings were very irregular, but under optimum conditions the viscosity-time curve was similar to an exponential curve. The empirical equation $\eta — \eta = ae^{kt}$ was submitted for determining the change in apparent viscosity during gelation; the temperature *t* when *k* the rate of gelation becomes zero being taken as the maximum gelation temperature, above which the sol was relatively stable, with time, and below which a part or the whole of the dispersed particles aggregated to form a gel structure.

The second part of this paper dealt with the reverse problem, namely, the viscosity changes associated with the gel to sol transition. From experiments made on different concentration systems at various temperatures, it was found that when the gel was warmed there was a rapid decrease in viscosity but the rate of change rapidly diminished with time, until a fairly constant viscosity was reached. The time taken to attain this constant viscosity was affected by the age of the gel and its previous treatment; mechanical treatment preventing gelation and hastening solation. Sometimes with an apparently fluid system an abnormal viscosity indicated the continued existence of the gel structure in the system. The viscosity-time curves of the gel to sol transition resembled to some extent the mirror images of the viscosity time curves obtained during gelation.

The next paper treated of the scattering of light by organosols of cellulose acetate in benzyl alcohol. On cooling the sol the intensity of scattered light at first gradually increased, until a temperature termed the maximum gelation temperature was attained. After this the rate of change of the intensity began to increase rapidly, and the system became opalescent, and in some cases translucent. At a lower temperature a point of inflexion occurred in the curve, the system set to a firm gel, and from this point onward a steady decline in the rate of change of intensity of scattered light was observed, with diminishing temperature. When a gel was warmed a practically identical curve was obtained, but having a definite shift in position corresponding to the hysteresis effect between "setting" and "melting." It was also found that the Tyndall number was affected by mechanical treatment, rate of gelation, and time.

In his last paper Mr. Mardles discussed the changes of volume and refractive index associated with: (*a*) the formation of organosols and gels, and (*b*) the reversible sol to gel transition, and concluded that:—The volume changes were smaller than those observed by other workers, using hydrosols and gels, and were largest (1) at the lower concentrations; (2) at higher temperatures; and (3) with the best solvents and optimum solvent mixtures. A small volume change varying with time was associated with the reversible sol to gel transition, during which there were indications of a change in the refractive index corresponding to changes in volume and Tyndall number. During the discussion, in which the president, Professor Porter, and Messrs. Hatschek and Highfield took part, it was suggested that Arrhenius's formula should be used instead of the empirical one given above, and that since the substances used introduced no disturbing chemical changes, the volume changes would be purely physical and might be found to agree with a formula of the type

$$V = Am_1^2 + Am_2^2 + Bm_1m_2.$$

Prof. J. R. Partington and Mr. W. G. Shilling submitted a paper on the variation of the specific heat of air with temperature, an investigation which they were led to undertake on account of the great difference in results obtained by previous experimenters. The method adopted was to measure the wave lengths of sound of constant frequency in a gas maintained at the required temperature. The authors found that by plotting molecular heat against temperature a linear curve was obtained up to 700° C. Above this temperature the tube used was too short to give results upon the accuracy of which they could depend. Arrangements, however, were being made to repeat the experiments with a longer tube, and it was hoped that reliable results would be obtained with temperatures up to 1000° C. and above. The gas used in the experiments consisted of air free from carbon dioxide, but the authors pointed out that the apparatus could be equally well used for other gases, and stated that it would be used in this way in the near future.

THE CHEMICAL SOCIETY

At the meeting held on January 18, Sir James Walker, who presided, announced that the Council had nominated Prof. W. P. Wynne as the next President, and Prof. J. F. Thorpe as the Treasurer of the Society. Four papers were presented.

The first Paper, entitled "The Estimation of Acetone in Methyl Alcohol and the Purification of Methyl Alcohol by Sodium Hypoiodite," by H. H. Bates, L. M. Mullaly and H. B. Hartley, embodied experiments on the application of the well-known Messinger method for the estimation of acetone. Mr. H. B. Hartley, who communicated the paper, emphasised the fact that a small quantity of iodine was used up even when the methyl alcohol was perfectly free from acetone, and accordingly a standard procedure had been worked out which took account of this fact. Further, the action between hypoiodite and acetone had been developed by the authors as a means of obtaining acetone-free methyl alcohol. In the discussion which followed Prof. J. C. Philip stated that experiments carried out in his laboratory some time ago indicated a slight disappearance of iodine in the Messinger process, even when organic substances were entirely absent. Mr. Hartley stated in reply that their blank experiments did not suggest such disappearance of iodine.

The second paper, on "Rhythmic Crystallisation," by W. E. Garner and F. C. Randall, dealt with this curious phenomenon as observed in the case of undecylic, myristic, lauric, and caprinic acids, the crystals being due to the formation of a solid skin on the surface of the liquid acid which wrinkled after the passage of the wave of crystallisation. The paper led to some interesting remarks by Prof. C. H. Desch, from which it appeared that records of such crystallisation are fairly frequent in the literature, the phenomenon being exhibited perhaps most effectively by potassium dichromate. It was further suggested that rhythmic crystallisation and the formation of Liesegang's figures were due to the same causes and might be similarly explained.

Two other papers were also read, "The Densities of Dilute Solutions of Potassium Salts and the Volume Changes occurring on Solution," by H. B. Hartley and W. H. Barrett, and "The Chemistry of the Glutaconic Acids. Part XIV. Three-carbon Tautomerism in the Cyclo-propane Series (Addendum)," by F. R. Goss, C. K. Ingold and J. F. Thorpe. Mr. Hartley stated that for the determination of solution densities, a 25 cc. Ostwald pyknometer was used, and at nearly constant temperatures it was possible to obtain an accuracy within 2 or 3 units in the 6th decimal place. The usual contraction on solution of a salt was 20–30 per cent., but potassium iodide presented an exception compared with the other halogen salts of potassium.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

At the meeting held on December 20, an interesting paper on industrial syntheses starting from acetylene was read by Prof. A. Guyot, director of research to the Compagnie des Produits Chimiques et Electro-métallurgiques d'Alais, Troyes et Camargue.

Of the syntheses using acetylene as a starting point, those of acetaldehyde, acetic acid, and chloro-derivatives had found industrial application, others offered hopes of success, and some required to be perfected before they could compete with other processes. After describing the production and uses of tetrachloroethane and trichloroethylene, the lecturer discussed the problem of liquid fuels and explained that although the industrial synthesis of alcohol was not yet economically possible, the catalytic condensation of aldehyde to metaldehyde and paraldehyde offered possibilities. Metaldehyde manufactured by this process was sold in small tablets as a substitute for "solidified" alcohol, but the process had the disadvantage that the yield, as would be expected from theory, was small. The yield of paraldehyde, however, was higher and this product should eventually become an important liquid fuel, as it could be produced more cheaply than alcohol derived from calcium carbide. Processes were being studied on a semi-large scale to utilise the ethylene from coke-ovens for the manufacture of alcohol.

MATTER AND ENERGY

(*Continued*)

BY SIR W. J. POPE, K.B.E., F.R.S.

During the latter part of the nineteenth century many isolated experimental observations were recorded, which indicated that our knowledge of the nature of matter and energy was far from complete and that new, but obscure, domains of science were continually obtruding themselves. In 1896 the French physicist, Becquerel, discovered the phenomena of radioactivity; he observed that compounds of the element uranium have the property of making the surrounding air a conductor of electricity. Shortly after, Madame Curie found that this property is exhibited much more strongly by a new element, radium, of atomic weight 226, which she had discovered; from any material containing radium a continuous stream of a gaseous substance perpetually emanates and renders the surrounding space an electrical conductor. In 1903, Ramsay and Soddy proved that when this gaseous emanation from radium is preserved, the element helium, of atomic weight 4, is produced. Further investigation showed that this remarkable behaviour of radium is due to the disintegration of the atom of the element, and that as a result of this atomic disintegration radium becomes converted into other elements.

Radium, in whatever form present, is perpetually emitting two kinds of rays, distinguished as α-rays and β-rays; it is, indeed, giving out a third kind, the γ-rays, but these are of minor importance to our present object and need not be further discussed. The α-rays consist of helium atoms carrying a positive electric charge and are expelled from the radium atom at a speed of roughly one-twentieth of the velocity of light, namely, about 12,000 miles per second; each gram of radium throws off about 145,000 billions of α-particles per second and each of these during its rapid flight through the surrounding air becomes converted into an atom of the element helium. When a radium atom ejects an α-particle it becomes itself converted into an atom of another element, the radium emanation or niton; the process thus consists in the radium atom, of atomic weight 226, expelling a positively charged helium atom of atomic weight 4, leaving an atom of niton of atomic weight 222. It must be noted that all the atoms of radium are not undergoing transmutation at the same moment; certain of the atoms in the mass explode from time to time, yielding positively charged helium and niton, and it has been found possible to determine the frequency with which these explosions occur; they occur at such a rate that one-half of any given mass of radium will undergo transmutation into helium and niton in about 1600 years. The reflection will immediately arise that if an atom of a radioactive element is born into the world, lives, dies and leaves a succession, it must have ancestors or progenitors; experimental investigation shows that this is the case. The element radium is but one phase in a long series of radioactive transmutations, in which the most distant ancestor, so far as we are as yet aware, is uranium, and the last descendant, as yet traced, is the metal lead. Uranium, of atomic weight 238, has an average life of about 7,000,000,000 years, and by discharge of an α-particle becomes converted into its successor, of atomic weight 234, and helium; the successor in turn lives and dies and the genealogical table has up to the present been investigated through some seventeen generations.

Many radioactive transmutations occur with the emission, not of an α-particle, but of a β-particle; the β-ray has been identified by Sir J. J. Thomson as the particle of negative electricity, the electron, discharged from the atom with a velocity which varies between one-third of the velocity of transmission of light and the velocity of light. It has been already pointed out that the α-particle has the mass 4 compared with the hydrogen atom as unity; the β-particle has a mass of about 1-1800th of that of the hydrogen atom. A radioactive transmutation, which involves the expulsion of an α-particle thus leads to the production of helium and an element four units less in atomic weight than the parent element; one brought about by the shooting off of a β-particle or a negative electron leads to no appreciable or measurable change in atomic weight.

Each radioactive transmutation which has been studied, is found to proceed at a definite rate, which is invariable, and quite independent of the state of chemical combination of the element and of the physical state of the material.

Sir Ernest Rutherford has thus been able to devise a model of an elementary atom. The atom, as he has imagined it, consists of a nucleus in which is concentrated the greater part of its mass; the atomic nucleus thus contains all the particles of positive electricity present in the atom and in most cases it also includes a definite number of particles of negative electricity. The positively charged nucleus is the centre of an external atomic domain, which is of much greater dimensions and in which the remainder of the electrons making up the atom are distributed. The atom is thus imagined as built up entirely of particles of positive and of negative electricity, the positive particles being all concentrated in the atomic nucleus; the nucleus carries a positive charge, which is equal to the difference in number between the positive and negative particles of which it is composed. This positive charge is a very important characteristic of the element and is represented by the *atomic number.* The external atomic domain is large in size compared with the nucleus—in the case of the element gold, for instance, the volume of the nucleus is about 1-20,000th part of the volume of the whole atom—and it contains electrons equal in number to the atomic number, that is to say, its negative electric charge is just sufficient to neutralise that of the positively charged nucleus. Since the atomic shell carries most of the negative particles and the nucleus contains all the positive particles it is obvious that the shell would collapse on to the nucleus unless the electrons were in vigorous motion. The atom must therefore be pictured much as a miniature solar system in which the sun is represented by the positive nucleus and the planets by the electrons in the external atomic domain; the β-particles are thus moving in orbits around the positive nucleus. The conception of atomic structure formed by Rutherford has been extended and developed by others and its mathematical treatment has led to rapid progress in the interpretation of the spectra of the elements; in accordance with it the atom of hydrogen is represented by a nucleus consisting of one particle of positive electricity and an external exterior atomic domain in which revolves one electron, or particles of negative electricity.

We know, however, that the hydrogen atom minus one unit of negative electricity is the hydrogen ion of the chemist, the carrier by which an electric current is transported through an aqueous solution; the ion or positively charged hydrogen atom thus appears to be merely the atomic nucleus of the hydrogen atom deprived of the exterior domain and to be identical with the particle of positive electricity.

Consider the bearings of the conclusions resulting from the mathematical interpretation of experimental observations made on radioactivity, upon such a question of general interest as the age of the earth. The earth receives heat from the sun, and it may be noted that, in general terms, all animal and vegetable life on our planet is perpetuated by the continual flow of energy from the sun at a perfectly definite rate; it is known that on the average each square centimetre of the earth's surface receives per minute two calories of heat, that is, sufficient heat to raise the temperature of two grams of water by 1° C. The mass and the distance of the sun being known, it follows from calculation that each gram of the matter contained in the sun emits annually about two calories. This emission of energy has gone on for at least a thousand million years, as is shown by geological records, and was probably going on ten thousand million years ago, before the moon came into existence and when the terrestrial day was only three or four hours long. During this period each gram of the sun's mass has thrown off something like ten thousand millions of calories, a quantity far greater than could have been supplied by energy of impact with satellites or by any known chemical reaction. We see now that in our solar system the energy required to keep up this rapid flow of heat from the sun to the earth must have been supplied by radioactive transmutations.

Until a few years ago it had always been supposed that each of the 90 or so chemical elements known to us consisted of identical atoms; this indeed was one of the postulates of Dalton's atomic theory. It was supposed, and this was confirmed by accurate measurements, that the atomic weight of an element—namely, the mass of the atom compared with the mass of an atom of hydrogen as unity—was invariable and represented one of the fundamental constants of nature. Further, experiment showed that the atomic weights of the elements were, in general, fractional numbers and were only in a few cases whole numbers within the limits imposed by possible experimental error; these observations and conclusions do not accord with the subatomic theory of matter and energy. The energy changes which occur throughout a series of radioactive transmutations are small when measured in terms of mass, and a radioactive transmutation brought about by the emission of an α-particle should result in a diminution of the atomic number by just two units and a fall in atomic weight of almost exactly four units. The emission of a β-particle, or electron, should raise the atomic number one unit and leave the atomic weight practically unchanged. This indicated change of atomic weight by almost precisely four units which should occur so frequently in radioactive series and the indication that the mass of an atom is, but for a minute fraction, measured by the whole number of particles of positive electricity contained in the atomic nucleus, suggests that the atomic weights should be whole numbers, the mass of the positive particle, the electrically charged hydrogen atom, being taken as unity. It was indeed stated by Prout early in the nineteenth century that the atomic weights are whole numbers, that of hydrogen being unity, but Prout's hypothesis did not withstand the test of experiment and was rejected.

On applying these considerations to the two chief radioactive series, the one beginning with uranium and the other with thorium, it would appear that each should end with the element of atomic number 82, lead, but that the atomic weight of the lead produced from uranium should be 206, whilst the lead formed by the radioactive disintegration of thorium should have the atomic weight 208. This has been shown to be true by Aston's work on isotopes. The latest mode of transmuting the elements is due to Rutherford, who, by using the α-particle as a projectile, has split nitrogen into helium and hydrogen.

ARTS AND SCIENCES

This is one of the toasts *de règle* at Royal Society Club dinners. What may not be included under such label it is difficult to say. As a student of both, I attended at the *Arts* on Wednesday, the 17th. The fog outside was perfect—the night was truly one for Lord Newton and the Smoke-abators. Inside, the dish provided was *Hygienic methods of Painting*, white lead being understood—a suitable enough topic for the newly whited sepulchre of pious opinions in which we met. A summary of the paper was given last week. The question debated was whether it were better to rub down dry or wet—the wets had it.

The chair was most appropriately occupied by Dr. Legge, whose services to industrial hygiene are well known. He spoke in terms of high praise of the constructive aid given by Mr. Klein, not only to the paint industry, but also in connection with lead frits to the pottery trade and more recently to the rubber industry by the introduction of a dustless litharge-rubber mixture, which is easily incorporated. In concluding, Dr. Legge dealt with the difficulty of dealing with the human factor. A competent psychanalyst—if such there be—might have based an interesting study upon his remarks. Primarily, he appeared to be humanitarian, swayed by sentiment; secondarily, the Government Departmental Officer and Factory Inspector, desiring to minimise the work and cost of inspection: a lurking subconscious desire to prohibit, rather than to regulate, seemed to flicker through the plea he put forward in this latter capacity that the Englishman's house is his castle, and that the Inspector can claim no right of entry. Such tendency is very dangerous, and may easily lead to the interests of industry being overlooked.

The discussion was discursive and of no practical value. One humorous speaker, the purpose of whose remarks was in nowise clear, implied that our salvation was to come from the great country where everybody is seeking to protect himself against himself and proclaim himself untrustworthy.

Professor Armstrong referred to the important constructive work done by Mr. Duckering, a Home Office Inspector, in devising an economic method of sterilising anthrax-infected wool, together with that of Mr. Klein as showing how much better it was to deal with problems of industrial hygiene by constructive remedial action, rather than by laying down regulations penalising the manufacturers' liberty and interests.

On Friday I studied skating on films far more tenuous probably than the thinnest ice can ever be, in Faraday's home. The veteran successor of the great philosopher, now in his eighth decade, gave the opening Friday evening discourse and dealt with the work on soap films to which he has devoted his attention during the last four of the fourty-four years of his Fullerian professorship. Those who attend the R.I. lectures are aware that Sir James Dewar's lectures are always the occasion for the masterly, daring and entrancing displays of an experimental dexterity and resourcefulness entirely his own, the lecture being for the most part verbal linkage and by-play.

He dealt with the problems of vortex motion, produced by air currents projected at the surface layer floating on the black film to which soap solutions are ultimately reduced by drainage. The effects following the discharge, through a pinhole orifice, of a current of clean air, at various rates, upon an upright film were projected greatly enlarged upon the screen During at least twenty minutes a large audience witnessed probably the most fascinating display of patterned interference-colours ever given. Those who could in any way picture the complexity of the figures the dancing molecules were forming, in the light of recent work on the orientation of molecules on plain surfaces, had full opportunity to wonder.

A Wanderer in Society

CORRESPONDENCE

SAFEGUARDING OF INDUSTRIES ACT: THE CALCIUM CARBIDE INQUIRY

Sir,—I beg of you to allow me to submit the following remarks upon Sir William Pope's article upon the Calcium Carbide Inquiry and your Editorial reference thereto.

No one will question that in Acts of Parliament, at any rate, it is desirable that language which has a clear and definite meaning should alone be used. If an expression such as "synthetic organic chemicals" occurs in an Act of Parliament, it is desirable that its meaning should be so definite that the public, assisted by properly qualified advice, may know with reasonable certainty whether it does or does not include any particular chemical compound. As the expression "synthetic organic compound" is essentially a scientific term used by chemists, its meaning and, accordingly, the fact whether a substance, *e.g.*, calcium carbide, is or is not such a compound, should be determined by the evidence of chemists. The above-mentioned inquiry unfortunately disclosed the fact that the chemists were divided in their opinion upon the question whether calcium carbide is a synthetic organic compound. "The master minds in chemistry have the right to lay down the definitions of their science"—as your Editorial rightly maintains—but the learned Referee had the duty of deciding whether the evidence established the applicant's contention that the expression "synthetic organic chemicals" so clearly includes calcium carbide that the substance was improperly excluded from the Board of Trade list. He considered the evidence and held that the applicants had failed to establish this position.

All will acknowledge the respect due to and the value of the opinion of so distinguished a chemist as Sir William Pope upon the meaning of the expression "synthetic organic compound." If, however, it be assumed that the learned Referee came to a conclusion with which the majority of chemists would disagree, such expressions as "the proceedings degenerated into an orgy of misapprehension and misinterpretation," and "these Board of Trade inquiries have become ridiculous farces played to the shame of British methods of legal procedure," would not, I submit, be justified thereby. Sir William's article appears to me to confuse the issue which I ventured to raise in my letter to *The Times*. I was not concerned to express, and did not express, any opinion upon the question whether Calcium Carbide is a synthetic organic chemical. I was concerned with his criticisms of the conduct of the inquiry.

Sir William in his letter to *The Times* gave his reason why "these Board of Trade inquiries have become ridiculous farces "—I need not further quote his words. He stated that it was because the Referee was not given the assistance of a chemist as assessor. I may, I think, claim to speak with some experience of legal proceedings in which questions of scientific fact have been the main issue. Under the Patents, Designs, and Trade Marks Act, 1883, as also under the Patents and Designs Act, 1907, in any action or proceeding for infringement or revocation of a patent, the judge might, if he thought fit, and on the request of either party to the proceedings was bound to, call in the aid of an assessor, specially qualified, and to try the case wholly or partially with his assistance. The Act of 1919 has substituted the word " all " for " either " of the parties, but otherwise has left the provision unchanged. During the period of almost forty years that these statutory provisions have been in force, there are probably not more than half-a-dozen reported cases in which the assistance of an assessor has been called in aid. The reason for this is that, in the opinion of those best qualified to judge, the true determination of the issues of scientific fact is not facilitated by adopting such a course. I wonder whether Sir William thinks that the learned Referee would have had the assistance he regards as desirable, had the assessor been one of the eminent gentlemen who gave it as their opinion that calcium carbide was not a synthetic organic compound.

In his letter to *The Times* Sir William stated that the learned Referee on a false translation of a German definition declared calcium carbide not to be an organic chemical and on this erroneous translation rejected the application. I am unaware that the Referee went so far as to declare Calcium Carbide not to be an organic chemical. He certainly did not do so nor reject the application on any false translation of any definition. The definition referred to occurs in Meyer and Jacobson's *Lehrbuch der organischen Chemie*. I agree it was wrongly translated by one of the chemists called on behalf of one of the opponents. It was one element but only one in the evidence, upon which as a whole the Referee decided to reject the application. Sir William is further in error in stating, as he does in his article, that this mistranslation was used to contradict the definition in Richter. The Referee rejected Richter, who says in terms calcium carbide is an organic compound, because he also states that carbon monoxide and dioxide are organic compounds, whereas the bulk of the witnesses called were not prepared to go so far. If the conduct of the inquiry is to be criticised, it is important that the reasons for the decision should not be misstated.—I am, Sir, etc.,

Arthur Colefax

The Temple, London,
January 18, 1923

THE JOURNAL

Sir,—Three technical chemists, each having different interests, met recently and the conversation turned to the new publication of the Society of Chemical Industry. These chemists are not beginners in technical chemistry, having in two cases been engaged for 20 years each, and in the other case for 10 years, and it was felt that their opinions might be useful as representing the views of members to whom the chemical literature of applied chemistry is an important matter. All three were specialists and were well acquainted with the current literature dealing with their particular interests, but all confessed a wider interest than this and generally agreed the necessity of a readable and authoritative journal, embracing pure and applied chemistry in all its branches.

As it now appears that this want will be fulfilled by the new *Journal*, it was decided to offer you the following suggestions for improvement as a basis for discussion, in the hope that something useful might result :—

1. The present abstracts contained in the *Journal* do not cover a sufficiently wide range of contemporary literature ; in many cases trade journals are entirely ignored.
2. The absence of abstracts dealing with pure chemistry is a serious deficiency, and it was felt that some arrangement should be possible whereby members of the Society of Chemical Industry could obtain abstracts dealing with pure chemistry such as those issued by the Chemical Society.
3. There should be some agreement between the various societies by which it would be possible for members of any one society to purchase, at a reasonable price, abstracts relating to all branches of pure and applied chemistry. These should be issued, not only in book form, but also in the form of single printed slips, suitable for use in a card-index filing system—a method already adopted by the Institute of Metals. The present multiplicity of societies, journals and abstracts means much duplication and is costly—the latter point being by no means unimportant to-day.
4. The new *Journal* should preach and preach again the desirability for the unification of existing societies and the Federal Council should make some real effort to materialise the dreams of a central palace of chemistry.
5. The human side of chemistry and chemists should receive more attention than in the past, and the literature should be made lighter and not so indigestible as it is to-day. The activities of the Council should be recorded in the *Journal* in such a way as to sustain the interest of the members in the doings of those who have been elected to look after the interests of the Society, and the curtain should be occasionally drawn aside to show that the Society does more than merely produce a journal.

6. The columns of the *Journal* should become a recognised medium for the exchange of views on matters concerning chemistry and industry, giving the broadest meaning to chemistry and industry.

We all congratulate the Council on its decision to produce a weekly *Journal*, for this is a sure sign that the Council realises the necessity of moving with the times, because in these days when the chemist is almost submerged in a sea of technical literature, he is prepared to take small doses of general chemistry at frequent intervals, but when he receives his literature *en masse*, lack of time frequently compels him to read only in the narrow channel in which his immediate interests lie. With best wishes for the future success of the *Journal*, I am, Sir, etc.,

London, "ONE OF THE THREE."
January 17, 1923.

PRICES OF GERMAN PERIODICALS

Sir,—Professor Browning's letter in your last issue is opportune but does not expose the true import of the great disparity between the charge for Beilstein and German chemical periodicals within and without Germany. This and a number of chemical periodicals now appear under the auspices of the "Verlag Chemie, G.m.b.H.," a publishing combine of the chief German chemical societies.

A list issued in June, 1922, shows that home members of the German Chemical Society were paying 110 marks per annum for the *Berichte*, whilst English members were paying 55 shillings per annum; the English member was thus paying about 40 times as much in gold values as the native. Early in December, 1922, a notice was issued fixing the price of volume 430 of *Leibig's Annalen* at 170 marks in Germany and 2·15 dollars for the foreigner; the ratio in gold values is roughly as 1 to 90. A recent statement on the finances of the German Chemical Society (*Ber.*, 1921, **54** A, 27) notes that about one-thirteenth of the members reside outside Germany.

Calculation from the above data shows that the small number of foreign members of the German Chemical Society are contributing a total of the order of eight times as much in gold as the home members in subscriptions to the society. The policy has thus been adopted of maintaining the home membership of the society by making the foreigner pay nearly the whole of the annual subscriptions.

Data for 1923 are not available because the inset stating the cost of the Society's publications is now withheld from exported journals; but a recent note in the *Berichte* indicates that a new method of fixing subscriptions is to be adopted. The cost will now be the "Grundzahl 20 x Schlüsselzahl des Verlager-Vereins (am 9. XII. 22 : 400)"; this cryptic formula doubtless expresses renewed confidence in the maxim that Heaven helps those who help themselves.

No exact figure can be assigned to the ratio between internal and external subscriptions to German scientific societies because payments are demanded from the foreigner in his national currency according to a stated scale; this facilitates the retention of balances abroad, but must cause vexatious complications in book-keeping. When the mark has been repudiated, and all internal and external German indebtedness thereby discharged, Germany will be in an excellent position for introducing a scientific currency, based upon a unit of ten grams of gold worth about thirty shillings, with which to express the capital value of her vast industrial concerns. Such a currency should quickly become international.

Since Germany has been permitted to pay her national debts by selling paper marks abroad and has persuaded the foreigner to pay the subscriptions of her nationals to her learned societies, it follows as a natural sequence that the plea, put forward by Professor von Harnack in the *Nation* and the *Athenæum* for December 2 last, that foreign resources for the support of scientific education and research should be shared with Germany, is a logical and indeed a moderate one. The eminent signatory of the notorious manifesto of the 93 in 1914 tells us that civilisation is doomed unless scientific research in Germany is subsidised from the outside; the catastrophe may be averted if the resources of the Research Fund Committees of the Royal Society and the Chemical Society, of the Belgian, French and American Academies, and of the Department of Scientific and Industrial Research are placed at the disposal of the Kaiser Wilhelm Institut in Berlin.

Dr. Browning expresses the hope that the English and American Chemical Societies will soon be able to issue a compendium of organic chemistry. The German Chemical Society, which with the outside aid described above, has just reached a record membership of 3,500, issues a very comprehensive work of this kind —Beilstein—and its present flourishing circumstances have recently justified it in undertaking a further great effort in the production of a compendium of inorganic chemistry. Our Chemical Society, with a membership of 3,900, our Society of Chemical Industry, with a membership of 5,600, and the American Chemical Society, with a membership of over 15,000, command a revenue enormously greater than that of the German Society and include many men with more pronounced talents for organisation and lexicography than are available in Germany. There is but one reason which hinders the production of Anglo-Saxon chemical compendia which avoid the many imperfections found in the German ones, namely, the need of capital; this is easy to find in Germany and it remains to be seen whether the recent appeal for funds for this purpose issued by the

Federal Council will furnish the money required for launching a British or an Anglo-American publishing scheme.

During the last few years the chemical abstracts available outside Germany have been greatly improved. The American "Chemical Abstracts" are more complete, and the English abstracts issued by our two large societies are more carefully compiled than those of the *Chemisches Zentralblatt;* the French abstracts are also much more comprehensive than they were a few years ago. There seems now no reason why the *Zentralblatt* should circulate outside Central Europe.—I am, Sir, etc.,

LEGISLATION AND THE MILK SUPPLY

Sir,—Prof. H. E. Armstrong, in his article on "Legislative and Departmental Interference with Industry and the Common Weal," states, *inter alia:* "The Ministry of Health has secured the passing of a measure, . . . which will legalise the application to milk of an unnatural treatment known to have a most definite and, without hesitation be it said, detrimental effect upon its food value."

I feel that this statement cannot be allowed to pass unchallenged as it is, I believe, not in accordance with the evidence that we possess.

The regulation referred to, in addition to establishing a bacterial standard, requires all milk sold as pasteurised to be heated to 145° F. for 30 minutes. This was undoubtedly prescribed upon scientific advice because it ensures practical destruction of pathogenic organisms *without causing any chemical change.* Milk pasteurised in this manner shows neither precipitation of albumin nor phosphates; no coalescence of the fat globules—*i.e.*, the cream line is unaltered; the time required for rennin coagulation is not increased; the enzymes remain intact; and the anti-scorbutic properties are undiminished. So far as I am aware, there is no chemical or biochemical test by which milk, pasteurised according to the regulations, can be distinguished from the raw product.

Practical feeding tests on a large scale have been carried out in the depots established by Nathan Strauss in New York, and by Geo. Oyster, Jr., in Washington, D.C., and the results showed that pasteurised milk (milk heated to 145°F. for 30 minutes) was not inferior to good-quality raw milk in any way.

I must also confess to being unconvinced as to the connexion between dental caries and legislative interference with milk. Milk, whether raw or pasteurised, will not tend to develop either teeth or jaw as its imbibition demands no effort from these organs.

Joseph Race

Hafod Road, Hereford, Jan. 19, 1923.

THE LATE DR. LUNGE.

Dr. Lunge completed his scientific education in Germany, and after gaining the degree of Ph.D. he came to the Tyne, where I first met him about the year 1870, with the object of obtaining an appointment as chemist in one of the twenty-six alkali works then in full operation there. He told me at that time that he made personal application to the senior partner of one of the largest of the Tyne manufacturers, who offered him a post as chemist in their very large works at £1 per week, which Dr. Lunge naturally refused, as the suggested remuneration was only 2s. per week above the rate of wages paid to labourers at that time. Although much discouraged by his first attempt to obtain an appointment in which his wide scientific knowledge and training might be put to good use, he persevered in his personal applications to the numerous other chemical manufacturers, and finally secured an appointment as chemist, and afterwards as manager of the Tyne Alkali Co., whose works were situated in South Shields. It was in these works, over a period of some years, that he obtained his practical knowledge of the management of alkali works and also of the control of workmen, who were at that time beginning to give trouble, as the first Trade Union in the chemical industry was formed on Tyneside about 1870. The Tyne alkali works were owned by Messrs. Baily Bowron & Co., and eventually Dr. Lunge married Miss Bowron, by whom he had several sons and daughters.

During his sojourn on the Tyne he took a most active interest in the proceedings of what was then called the Newcastle Chemical Society, which was eventually merged in the Society of Chemical Industry. He read many scientific papers before the members of that society, and became well known to all the scientific men and manufacturers on the Tyne, where his extraordinary energy, force of character, and high scientific attainments were soon fully recognised. He became so prominent in the Tyne chemical industry that, when a successor was required for the chair of technical chemistry at Zurich, he was chosen as the best man in Europe to fill that important position.

From 1870 to the time of his death, Dr. Lunge and I were close friends, and I have in my possession many letters received from him during his long sojourn in Zurich. These letters display his personal charm, as the following extracts indicate. Writing me on December 2, 1901, he said, "I am hard at work at a new edition of my book on 'Sulphuric Acid.'. . Looking at my age and the state of my health I must consider this book (which will be to a great extent quite new) as my last great work." Then again in April, 1907, he wrote me: "I have passed a very indifferent winter—no actual illness, but a general falling off of bodily strength and working power. Well, at my age I must be prepared to pay Nature its tribute." On November 15, 1908, he wrote: "Since I have been obliged to retire from my office, on account of my failing health, my literary work has been the main occupation of my life, and I strongly desire to finish it with a new edition of Vols. II. and III. of that work (Sulphuric Acid and Alkali), Vol. I. having appeared a few years ago." On December 2, 1908, he wrote me: "My dear friend,—So I surely may call you since you say yourself that we have been on an unbroken friendly footing for 40 years past. Your more than kind words on the value of my literary work, and your equally warm wishes for my well-being will be remembered by me to my dying day. They will greatly contribute to lessen the mental depression under which I have been frequently suffering since I have been compelled to give up my office by my declining health. Thank you, thank you, and accept my reciprocating wishes to the fullest extent."

Then again on April 4, 1911, he writes: "I cannot sufficiently express my feelings on receiving your letter of March 29th. This appreciation both of my person and my work on the part of a man on whom I have always looked not merely as one of my oldest friends, but also, as one of the very foremost in that branch of technical chemistry to which I have devoted the best part of my life, is simply priceless to me, and the greatest comfort I could have in the present rather precarious state of my health. That state as well as my advanced age (I am in my 72nd year) make it difficult for me to accede to the wish of my publishers to prepare a new edition of Vol. I. of 'Sulphuric Acid and Alkali,' the edition of 1903 being nearly exhausted. During the years following its publication I have collected a vast amount of material for a new edition, but I have now been so long away from really *practical* work in that field, that I strongly wish for the co-operation of a gentleman who is actually employed at one of the leading establishments and who could contribute information on what is the present practice of the best managed factories in the manufacture of sulphuric acid and of anyhydride. If you could point out such a man (who must, of course, be fully competent and acquainted with every part of the field), you would add another to the numerous tokens of friendship I have received from you for so many years past. Meanwhile take my heartiest wishes for your health and happiness and be assured of the everlasting friendship of your devoted G. Lunge."

I cannot claim that Dr. Lunge was as successful as a works manager as he was professor of technical chemistry in Zurich, but his great work in Zurich is well known to the chemical world, and many distinguished leaders of chemical industry received their chemical training under him. He is well known for his valuable improvements in analytical methods and for his research work, but his chief fame rests upon his books in connexion with the chemical industry, upon which he spent many years of his life. On these books he concentrated all his knowledge, brain power and wonderful industry, almost to the exclusion of all social life. These books are so rich in knowledge that when one refers to them on any subject in the alkali industry one never goes empty away, but always finds in them a wealth of information. In deploring the death of Dr. Lunge, who has lived more than the usual span of human life, the chemical industry of the whole world appreciates to the full the importance of his life work, and the great value of his books, which will be handed down from one generation to another. Dr. Lunge was an indefatigable worker, and although of a somewhat excitable temperament, had a charming personality. The world is considerably poorer for his death, and those engaged in the industry fully recognise and appreciate the great work of his life, whilst they also extend to the members of his family the expression of their sympathy for the loss of such a distinguished man, who has done so much for the chemical industry of the world.

Thos. W. Stewart

PERSONALIA

Dr. R. A. Peters, Fellow of Gonville and Caius College, Cambridge, has been elected to the Whiteley Professorship of Biochemistry in the University of Oxford.

Dr. Percy May has joined the staff of Reeves and Sons, Ltd., manufacturers of artists' colours and materials, as chief chemist and director of the laboratories.

Prof. A. Haller has been elected president of the Académie des Sciences for the year 1923.

At the annual meeting of the Union of Scientific Workers Prof. Dame Helen Gwynne-Vaughan was elected president of the Union.

The following awards have been made by the Geological Society:—Wollaston Medal, W. Whitaker; Murchison Medal, Dr. J. Joly; Lyell Medal, G. F. Dollfus; Bigsby Medal, E. B. Bailey; Wollaston Fund, H. H. Read; Murchison Fund, T. H. Withers; Lyell Fund, Dr. W. T. Gordon and Dr. W. N. Benson.

The Gold Medal of the Royal Astronomical Society has been awarded to Prof. A. A. Michelson, of the University of Chicago, for his application of the interferometer to astronomical measurements.

The death is announced of Dr. Carl Paul Goerz, the founder of the well-known firm of optical-instrument makers of the same name.

NEWS AND NOTES

UNITED STATES

Research on the Effect of High Pressures

According to the *Daily Telegraph*, Prof. P. W. Bridgeman, of the United States, has been able to obtain pressures up to 20,000 atmospheres and has investigated their effect on various substances. Under such enormous pressures, gases permeate metals; liquids become compressible, but with the exception of mercury, and contrary to the generally accepted opinion, do not permeate metals; and the physical properties of various substances become completely changed. It is stated that a solid steel wall is permeated by mercury (the exception mentioned above) under a pressure of 6000 atmospheres, and by hydrogen under a pressure of 10,000 atmospheres. Under a pressure of 12,000 atmospheres, water occupies 20 per cent. of its original volume and alcohol 27 per cent., paraffin and rubber become harder than soft steel, and phosphorus becomes black, non-combustible, and a good conductor of electricity. The new properties are stated to persist after removal of the pressure.

The Fixed Nitrogen Research Laboratory

Dr. F. G. Cottrell, the director of the U.S. Fixed Nitrogen Research Laboratory, states in his annual report that as yet fixed nitrogen cannot compete as a fertiliser with Chilean nitrate or coke-oven ammonia save under unusually favourable circumstances. Work has therefore been carried out on means of reducing the cost of working the cyanamide, synthetic ammonia, arc, and alkali cyanide processes. It appears, however, that any drastic reduction in the cost of operating the cyanamide process is improbable. Much work has been conducted on the transformation of nitrogenous compounds into technically useful materials, and a process has been developed on a semi-technical scale for producing urea from ammonia and carbon dioxide which promises to reduce the price of this material and so permit its use as a fertiliser. An extensive investigation is in progress on the chemistry of cyanamide and its derivatives, and methods have been developed for producing cyanamide (H_2CN_2) in quantity, for converting cyanamide into urea on a semi-technical scale, and for preparing guanidine salts. Cyanamide derivatives which appear to have value as ingredients in explosives have also been studied.—(*Chem. and Met. Eng.*, *Dec.* 20, 1922.)

CANADA

Bentonite

In Canada, the variety of clay known as bentonite has been found at Camrose, near the Red Deer River, in Alberta, and in the Nikola Valley, in British Columbia. Bentonite is especially valuable as a filler in the manufacture of paper and textiles, in which it has advantages over kaolin, and its use has also been suggested in soap-making (in which it can replace part of the soap substance), as a filler in rubber, leather, phonograph records, pressed and moulded insulating material, as a water softener and a base for toilet creams, as a carrier for printers' ink, and as a substitute for fuller's earth. The Canadian Department of Mines is investigating the deposits and seeking further uses for the material.—(*Ch. of Comm. J., Jan.* 5, 1923.)

Barium and Strontium Minerals

All the available information on barium and strontium minerals in Canada has been collected by Mr. H. S. Spence and published in the form of a report by the Canadian Department of Mines (Mines Branch No. 570, pp. 100). The chief source of barytes in Canada is Nova Scotia, the large deposits near Lake Ainslie, Cape Breton Island, having furnished practically the whole Canadian output. Scattered deposits in Ontario and Quebec have been worked, but the output has been small, and although large deposits have been discovered in Northern Ontario in the Langmuir, Elk Lake, and Matachewan areas, the Langmuir Mine has not reached the producing stage, and lack of transport facilities prevents development of the other deposits. Canadian barytes differs from that of the United States in occurring in veins, whereas the latter (Missouri ore) occurs in nodules and irregular masses, and is much softer. Analyses of a number of samples of Canadian barytes gave the following percentages:—$BaSO_4$ 86·60—98·67; $SrSO_4$ 0·70—6·20; $CaSO_4$ 0·30—4·50; $CaCO_3$ 1·60—8·21, the principal impuritie being small amounts of sulphides, calcite, fluorite, and sulphates of calcium and strontium. The output has fluctuated greatly; starting with 300 tons in 1885, it became 4312 t. in 1908, 3490 t. in 1917, and fell to 580 t. in 1918, and 468 t. in 1919, but rose to 751 t. in 1920. Several grinding mills have been established, but at the end of 1920, only one was in operation. The failure to establish the barytes industry in Canada is apparently caused by insufficient attention to trade requirements, the ground barytes being either too coarse, of a bad colour, or impure. The Canadian consumption of ground barytes, lithopone, and barium chemicals in 1920 is given in the appended table:—

	No. of firms	Ground barytes	Lithopone	Blanc fixe
			Lb.	
Paint	36	5,176,200	5,808,700	116,600
Rubber	13	1,328,000	1,065,600	30,000
Paper	5	—	—	280,000
Linoleum and oilcloth	1	—	1,600,000	—
Total	59	6,504,200	8,474,300	426,600

In addition 6000 lb. of barium carbonate. 550 lb. of barium chloride, and 77,500 lb. of barium peroxide were consumed in the rubber, paper, and drugs and pharmaceutical (4 firms) industries, respectively.

Only four occurrences of celestite of possible economic importance are known in Canada, and all of them are in Ontario; the largest deposit is at Bagot, Renfrew County, and is now being worked. There are three known occurrences of strontianite, but these are of mineralogical interest only. The report also contains general information on the sources and uses of barium and strontium chemicals.

GENERAL

The British Association

Sir Ernest Rutherford will preside over the meeting of the British Association for the Advancement of Science, which will be held in Liverpool from September 12—19, and the following have been elected sectional presidents:—

Section A (Mathematics and Physics): Prof. J. C. McLennan, F.R.S.; B (Chemistry): Prof. F. G. Donnan, F.R.S.; C (Geology): Dr. Gertrude

Elles; D (Zoology): Prof. J. H. Ashworth, F.R.S.; E (Geography): Dr. Vaughan Cornish; F (Economics): Sir W. H. Beveridge; G (Engineering): Sir Henry Fowler; H (Anthropology): Mr. P. E. Newberry; I (Physiology): Prof. G. H. F. Nuttall, F.R.S.; J (Psychology): Mr. C. Burt; K (Botany): Mr. A. G. Tansley, F.R.S.; L (Education): Prof. T. P. Nunn; M (Agriculture): Dr. C. Crowther. The local Secretaries are Mr. Edwin Thompson, Dr. A. Holt, and Mr. Walter Moon (Town Clerk).

Nickel

During the war nickel attained a sudden and phenomenal importance and the digest of statistical and technical information collected by the Imperial Mineral Resources Bureau (pp. 55. 1s. 6d.) on the production of nickel during the period 1913—1919 reflects this fact. The most important nickel ore is pentlandite, a sulphide of nickel and iron, and this is mined extensively in the Sudbury district of Canada. Other sources of nickel are New Caledonia, Norway, and Greece. Deposits, not yet worked commercially, are found in South Africa, Australia, France, Russia, Sweden, Cuba, and in the Dutch East Indies.

The world's production of nickel ore (in tons of metal) has been approximately as follows:—

	1916	1917	1918	1919	1920	1921
Canada	37,000	37.000	41.000	20,000	27,000	8,600
Germany ..	1,600	2,000	1,800	570	—	—
Greece	550	86	650	59	—	—
Norway	780	690	238	100	123	—
Sweden	35	49	24	4	—	—
New Caledonia ..	4,000	4,680	2,666	1.780	2.187	—
United States ..	820	360	394	456	326	99

Apparatus for Measuring the Specific Gravity of Gases in Small Quantities

In Technical Paper No. 5 of the Fuel Research Board (pp. 6, price 3d.), Mr. A. Blackie describes a manometric apparatus for determining the specific gravities of gases available in comparatively small quantities. Two determinations can be made with about 1·5 litres of gas, and for gases of specific gravities 0·4 to 0·6, relative to air, the results are correct to within ±0·5 per cent. The apparatus is similar to that devised by Sir Richard Threlfall (*cf.* J., 1907, 355), but shorter columns of gas and air are employed. In the present apparatus a column of gas and one of air, each contained in its respective vertical water-jacketed copper tube 24 feet long and ½ inch internal diameter are hydrostatically balanced against one another, and the differential pressure due to the columns measured by means of a Chattock tilting gauge. The mean temperature of the water jacket is determined by means of a constant-volume air thermometer. Some of the values obtained with the apparatus differed by as much as 3 per cent. from corresponding values determined by a Wright's effusion bell, and this is regarded as the maximum percentage error to which the latter method is liable when no correction for saturation of the gas with water vapour, viscosity, etc. are applied.

Chemical Society

The Anniversary Dinner will be held in the Hotel Cecil, Strand, on Thursday, March 22.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for January* 18)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm of agent	Materials	Reference number
Australia ..	Gold bronze powders; gold, silver and aluminium leaf; dry colours; aniline dyes	9751 E.D./ C.C.
Egypt ..	Photographic chemicals. plates, films, paper, etc. (tender for)	9726 F.E./ G.C.2
„ ..	Soap, paint, oil, alcohol, acids, grease, leather, steel, iron, copper, etc. (tender for)	9777 F.E./ G.P.
France ..	Raw coal tar	18106 F.W./ C.C.2
Latvia ..	Copper wire	6822 F.R./ E.P.
South Africa	Paper	71
Spain, Portugal, S. America	Steel bars, black and galvanised sheets, leather belting	7355 T.E.
United States	China, earthenware, stoneware ..	78
„ „	Tiles	79
„ „	Cement, rails (tender for)	17845 F.W./ G.C.2
Uruguay, Argentina	Glassware	80

TARIFF CUSTOMS EXCISE

Austria.—From February 29, all platinum goods produced in or imported into Austria must have a minimum fineness of 950/1000 and be stamped with the figure 950.

Brazil.—The proportion of duties payable in gold have been raised from 55 to 60 per cent., the proportion payable in paper money being reduced from 45 to 40 per cent.

Ceylon.—An ordinance has been issued prohibiting the export of rubber, save under licence, and limiting the exportable maximum per month to 60 per cent. of one-twelfth of the "standard annual production" of each estate. In addition an export duty is imposed of 2½ cents per lb., and a fee of ¼ cent per lb. is payable when not more than the exportable maximum has been exported in any one month.

Costa Rica.—Surtaxes have been applied to certain goods not affected by the "national tax."

Germany.—Solid artificial or coumarone resins may not be exported save under licence.

Mexico.—New import duties on glass bottles and jars vary from 6 to 20 centavos per kg. gross; the duty on carbonates of soda and potash is fixed at 1 centavo per kg. gross weight.

St. Lucia.—For importation, opium and other habit-forming drugs require a permit.

Straits Settlements.—Regulations controlling the sale of food and drugs may be consulted at the Department.

Tunis.—Particulars of the revised schedule of import duties may be obtained from the Department. The duties on picric acid, indigotin and other dyes are 20, 40, and 16 fr. per 100 kg. respectively.

REPORT

Report on the Economic and Financial Conditions in Brazil, dated September, 1922. *By* E. Hamblock, *H.M. Commercial Secretary, Rio de Janeiro. Department of Overseas Trade. Pp.* 66. *London: H.M. Stationery Office*, 1922. *Price* 1*s.* 9*d.*

Of the various States of Brazil Sao Paulo is by far the most flourishing, and its manufacturing industries, especially the production of chemicals, drugs, and pharmaceutical products, are expanding. Since 1915, local production of fertilisers has supplied the Union's requirements almost entirely, and only 13 tons was imported in 1921. Bauxite occurs in Minas Geraes and at Campinas, and chromite is found in Bahia and near Campo Affonso. Other Brazilian minerals include copper, lead, nickel, gold, clays, mica, lime, abrasives, graphite, ochres, saltpetre, pyrites, and mineral fertilisers; and various precious and semi-precious stones are also found. Minas Geraes possesses the largest deposits of iron ore. The Brazilian Government is disposed to protect the metallurgical industry and in 1921 gave power and concessions to the Anglo-Brazilian Iron and Steel Syndicate, Ltd. Negotiations for the acquisition of hydro-electric power for proposed iron and steel works to be erected by the Syndicate, will, it is anticipated, be soon completed and operations begun. Plans have been approved for the development of hydro-electric works at Pombos Island and the Mambucaba waterfall. By a decree in 1921, the Government of Minas Geraes granted favours to firms undertaking to manufacture iron and steel in any State of the Federal Union, and a reduction from 3 milreis to 200 reis per ton has been made in the State export tax on all ore destined for manufacturing purposes in Brazil. Deposits of manganese ores occur principally in Minas Geraes and Matto Grosso, but those in the latter State have never been exploited owing to the lack of transport facilities. No petroleum deposits of commercial importance have been discovered in the country. In Sao Jeronymo, 215,000 tons of coal was mined in 1921. Tests made in Britain, the United States and in Belgium with a view of employing Brazilian coal for the production of metallurgical coke are said to have given satisfactory results.

Total exports from Brazil during 1921 were valued at £58,587,000, compared with £65,451,000 in 1913 and £107,520,000 in 1920, the corresponding import figures for the same years being, respectively, £60,468,000, £67,166,000, and £125,005,000. During the war the United States supplied the greater part of Brazil's import trade. Official statistics for the first quarter of 1922 show that although Great Britain is again the most important source of Brazilian imports, the discrimination in favour of the United States and Belgium in the matter of certain imports from these countries still prevails. Early in 1922 an attempt was made to develop commercial intercourse between South Africa and Brazil; it is not anticipated that any great success will attend the project. British dyes would appear to be declining in price, whereas German dyes are apparently becoming dearer. Germany is interested in the acquisition of Brazilian dye-woods.

REVIEWS

(1) Inorganic Chemistry. *By* E. J. Holmyard. *Pp. xi*+560. *London: Edward Arnold and Co.*, 1922. *Price* 6*s.* 6*d. net.*

(2) An Inorganic Chemistry. *By* Prof. H. G. Denham. *Pp. viii*+683. *London: Edward Arnold and Co.*, 1922. *Price* 9*s. net.*

(3) Laboratory Exercises in Inorganic Chemistry. *By* J. F. Norris *and* K. L. Mark. *Pp. x*+548. *London: McGraw-Hill Publishing Co., Ltd.*, 1922. *Price* 10*s. net.*

(1) The reading and re-reading of this book has been sheer delight to the reviewer. It might appear that Mr. Holmyard undertook no very unusual task in writing what is correctly described by its sub-title as " A Text Book for Schools," and in the preface as " an attempt to present to students of the School and Higher Certificate Standards a logical course of chemistry which shall acquaint them with modern ideas and give them an insight into the problems, methods and achievements of the science." But the book he has produced is in fact remarkable, being, in the reviewer's opinion, quite literally and soberly the very model of all that such a book can and should be. It is not possible to write of it save in terms which appear exaggerated. The whole book is extraordinarily cleverly done ; it is the real substance of chemistry made living by the enthusiasm of a real chemist. Drastic selection, has, of course, been required to compress the whole subject of inorganic chemistry into some 540 small pages, but one is not conscious of it ; even after careful study one misses nothing whatever of basic importance. This book, in fact, differs from most text-books of chemistry big and little, in that it was obviously created not by whittling down the unwieldy mass of facts and theories which constitute chemical literature, but rather by the careful crystallisation of the author's own knowledge. From a goodly store of well-digested chemistry he has brought out the *essential* material, with nothing omitted, nothing redundant, and has written it down in logical order with perfect clarity, simplicity and conciseness of thought and language. One is indeed impressed by the skilful workmanship of the writing.

The general plan of the book is unusual and good : it falls into two main parts, one dealing with general theory, the other describing the elements in the order of the Groups of the Periodic Classification. The chapter headings in Part I. are :—Historical ; The Atomic Theory ; Equivalent Weights ; The Gas Laws ; Molecular Weight ; Atomic Weight ; Formulæ and Equations ; The Kinetic Theory ; Thermal Dissociation ; Electrolysis, Osmotic Pressure ; Chemical Equilibrium ; The Ionic Theory ; Catalysis, Colloids, Phase Rule ; The Periodic System ; Structure of the Atom. Each of these topics in turn is treated in a fashion which, whilst always "elementary," in the sense that it must command the interest and comprehension of any intelligent person, is most delightfully thorough, accurate and satisfying. At this stage in the progress of chemistry most teachers must feel how great are the difficulties in teaching the atomic theory; the author overcomes these difficulties in a characteristically direct and satisfactory manner by reverting to the actual historical development of the Daltonian theory and treating it as a hypothesis which, whilst excellent as a working guide in chemistry, is inexact in every particular. Mr. Holmyard has devoted much study to the history of chemistry and it is therefore not surprising that the historical treatment throughout is especially fresh, sound and attractive. Chapter XVI, on the Structure of the Atom, is very very good indeed; it has had the advantage of Professor Soddy's criticism, but it is apparent that the author must himself be given the credit for presenting, in the short space of 17 pages, a most closely argued, exact and yet entrancing (there is no other word which quite fits) account of recent developments.

After all this it may seem rather a shock to say that the book has many pleasant touches of humour, *e.g.*, as an exercise on the chapter on the atom, the request to "write an essay on the Clifton boy's dictum: *chemistry is a soul-destroying subject.*

But Mr. Holmyard believes that science "is the greatest of the 'humanities,'" and his book certainly does chemistry the very real service of presenting it in this light.

As constructive criticism attention may be drawn to a few misprints, *e.g.*, 22/4 litres for the G.M.V. five times in succession on page 64: the quantity is correctly stated as 22·4 litres on the next page; and *well* for *wall* on p. 102. Also, the boiling point of ozone is incorrectly given as—125 deg.

There seems no doubt that, as a school book, and for elementary students in university classes, this work *must* come into quite general use, simply through sheer excellence for that purpose: but it may be commended to a much wider public because no chemist, be his work in teaching, research or industry, can fail to derive from it much pleasure and profit.

(2) Professor Denham's book suffers in review by contrast with that just discussed. It is a general text-book of inorganic chemistry for university degree students constructed on the plan now usual, whereby, after a general introduction the non-metallic elements are discussed in the usual order with the interposition of chapters dealing with matters of general theory as they arise. But it is uninspired and, moreover, is marred by a number of rather serious errors and omissions. As examples the following may be cited, *inter alia:* The statement (p. 72) in heavy type that "the number of particles present in a colloidal solution is, under similar conditions of temperature and pressure, equal to the number of molecules of gas computed to be present in a corresponding volume of gas" seems to have no meaning; the definition of solutions (p. 113) as "mixtures which appear homogeneous in ordinary daylight, and which cannot be separated by ordinary mechanical means into their constituent parts," seems inadequate; after stating (p. 173) the contrast in solubility between the fluorides of calcium and silver and the other halides of these metals, the author says without further explanation, "Possibly this is connected with the tendency of hydrogen fluoride to associate in solution," which is at the best very obscure, whilst he does not anywhere point out that the abnormal boiling-point of hydrogen fluoride may be explained by its association in the liquid state. In the discussion of osmotic pressure the work states, again in heavy type, that "the osmotic pressure exerted by a dissolved substance is therefore identical with the gaseous pressure which that substance would exert, if the same weight of substance were in a state of vapour, under the same conditions of temperature and pressure." As examples of omissions it may be pointed out that the discussion of ozone (pp. 191–5) contains no reference to the Brodie ozonizer, or to Soret's work on the constitution of ozone, that the account of the allotropy of sulphur contains no reference to $S\lambda$ and $S\mu$ (p. 216).

In general it must be said that the book has no outstanding merit which might lead it to be preferred to other good textbooks now available.

(3) This laboratory manual is one more proof that conditions in American universities must be very different from those in our own. Many of the experiments described are of a very elementary nature, and some, such as the determination of density, specific heat and humidity, are purely physical.

Most university teachers here would take exception to the method of treatment: no intelligence or initiative is assumed or, apparently, desired of the student. The description of each experiment is preceded by a short "discussion" of the principle involved, and then by a list of "materials" to be obtained for the performance of the experiment; the description concludes with a list of numbered questions the answers to which constitute a report on the experiment and are supposed to be written on the blank page opposite.

Its utility is further limited by the fact that it is apparently written throughout with direct reference to a specific laboratory and its equipment and a specific course of instruction.

If its contents were reduced to one-third the book might possibly find a use in the teaching of school children just beginning experimental work in chemistry, but it is difficult to see how, in its present form, it can find useful application in English teaching.

H. V. A. Briscoe

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

No important changes in this market have been reported this week. Prices are as follows :—

Acetic Acid 40% tech.	£21.
Acid Hydrochloric	4s. to 5s. carboy d/d.
Acid Nitric 80° Tw.	£25 10s. per ton makers' works.

Acid Sulphuric, average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.

Acid Sulphuric, 94% arsenical, £6 10s. per ton makers' works.

Ammonia Alkali	£8 per ton.
Arsenic (White)	£65 to £75 per ton.
Bleaching Powder	£10 10s. to £11 10s.
Calcium Chloride	£6 per ton.
Copper Sulphate	£26 f.o.b.
Potash Caustic	£29 10s. to £30.
Salammoniac	£32 per ton d/d.
Potassium Bichromate	6¼d. per lb. d/d.
Salt Cake	£4 10s. to £5 10s.
Soda Caustic, 76%	£20 to £21.
Soda Crystals	£5 10s. carriage paid.
Sodium Bicarbonate	£10 10s. carriage paid.
Sodium Bisulphite Powder 60/62%	£19 to £20 10s. per ton, f.o.b. or f.o.r. London.
Sodium Chlorate	In slightly improved request. Foreign parcels offered at low prices.
Sodium Sulphide	£16.
Sodium Sulphite, Pea Crystals	£17 to £17 10s., 1 cwt. wooden kegs included.
Bisulphite of Lime	£7 per ton, packages extra and returnable.
Sodium Acetate 97/98%	£23 per ton.
Sodium Nitrite	£30 per ton 100% basis d/d.

WOOD DISTILLATION PRODUCTS

There are no changes to report in this section. Manufacturers' prices are as follows :—

Acetate of Lime brown	£8 per ton d/d.
,, ,, ,, grey 80%	£14 10s. per ton d/d.
,, ,, ,, Liquor	9d. per gall. 32° Tw. d/d.
Charcoal	£9 10s. to £10 per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 6d. ,, ,, Unrefin'd.
Wood Naphtha, Miscible	7s. per gall. 60% O.P.
,, ,, Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£4 10s. per ton d/d.
Brown Sugar of Lead	£36 per ton.

TAR PRODUCTS

Acid Carbolic, Crude 60's	2s. 5d. to 2s. 6½d. per gall. Market firm with fair inquiry.
Acid Cresylic, 97/99	2s. 2d. to 2s. 3d. per gall. Fair inquiry.
Acid Cresylic, Pale 95%	2s. to 2s. 2d. per gall.
Acid Cresylic, Dark	1s. 10d. to 2s. per gall. Little demand ; offers have been made as low as 1s. 6½d. per gall.
Anthracene Paste, 40%	7d. per unit per cwt. Price nominal. Practically no business being done.
Anthracene Oil, Strained	7¾d. to 10d. per gall. Small demand.
Anthracene Oil, Unstrained	7⅝d. per gall.
Benzole, Crude 65's	1s. to 1s. 2d. per gall.
Benzole, Standard motor	1s. 7½d. to 1s. 11d. per gall.
Benzole, Pure	1s. 10d. to 2s. 2d. per gall. Demand very small.
Toluole, 90%	1s. 10d. to 2s. per gall. Small demand.
Toluole, Pure	2s. to 2s. 4d. per gall. Small demand.
Xylol	Prices range very widely from 2s. 1d. to 3s. 6d. per gall.
Creosote Cresylic 20/24%	10d. to 11d. Fair inquiry.
Creosote, Heavy	7½d. per gall. Demand strong.
Creosote, Standard specification	7¼d. to 8¼d. per gall. Strong and scarce.
Naphtha, Crude	9½d. to 1s. 2d. per gall.
Naphtha Solvent, 90/160	1s. 6d. to 1s. 10d. per gall. Market weak with little inquiry.
Naphtha, Solvent 90/190	1s. 7d. per gall.
Naphthalene, Crude, Drained Creosote Salts	£5 to £7 per ton. Exceptional prices as high as £9 10s. are heard of. There is a good inquiry for this product.
Naphthalene, Crude, Whizzed or Hot Pressed	£8 to £12 10s. per ton.
Naphthalene Crystals	£16 per ton.
Naphthalene, Flaked	£15 per ton.
Pitch, Medium Soft	130s. to 140s. per ton. Very firm.
Pyridine, 90/140	12s. 6d. per gall.
Pyridine, Heavy	8s. to 9s. per gall.

INTERMEDIATES AND DYES

Business has not been up to the average of the past few weeks, but the general tone remains confident. The chief intermediates are quoted below carriage paid and packages included unless otherwise stated :—

Acid H.	5s. 1d. lb., 100% basis.
Acid Naphthionic	2s. 7½d. ,, ,, ,,
Acid Neville and Winther	6s. ,, ,, ,,
Acid Sulphanilic	1s. 6d. ,, ,, ,,
Aniline Oil	11½d., drums extra, or 10d. naked at works.
Aniline Salts	11½d. or 10½d. naked at works.
Benzidine Base	6s. 6d. lb., 100% basis.
Dinitrobenzene	1s. 3d. lb., 11d. to 1s. naked at works.
Dinitrotoluene, 48/50	8d. to 9d., naked at works.
Dinitrotoluene, 66/68	1s. 2d. to 1s. 3d., naked at works.

Diphenylamine	4s. 1d. lb.
α-Naphthol	2s. 9d. lb.
β-Naphthol	1s. lb.
α-Naphthylamine	1s. 6½d. lb.
β-Naphthylamine	4s. 6d. lb.
p-Nitraniline	2s. 9d. lb.
Nitrobenzene	8d. lb., drums extra.
Nitronaphthalene	1s. lb.
Naphthionate Soda	2s. 8½d. lb., 100% basis.
Diethylaniline	4s. 6d. lb., packages extra.
Metanitraniline	5s. 6d. lb.
Para Toluidine	5s. lb.
Para Phenylene Diamine	12s. lb., 100% basis.
Meta Phenylene Diamine	5s. 6d. lb.
Meta Toluylene Diamine	5s. lb.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid Acetic, 80%	44s. cwt., ex wharf London. Slightly higher.
Acid Acetyl Salicylic	2s. 10d. to 3s. lb. Remains steady, fairly active business.
Acid Benzoic	2s. lb. represents spot value.
Acid Boric B.P.	£61 per ton crystals, £65 per ton powder, packages in 2 cwt. bags; carriage paid U.K.
Acid Citric	1s. 8d. to 1s. 8½d. lb., less 5% for ton lots. Dearer with further advance likely. A new feature is the arrival of small supplies from the British West Indies.
Acid Gallic	3s. lb.
Acid Pyrogallic crystal	5s. 6d. lb.
Acid Salicylic	1s. 5d. to 1s. 6d. lb. Very good demand, market firm and advancing.
Acid Tannic	3s. 3d. lb. unchanged.
Acid Tartaric	1s. 2½d. lb. for ton lots, less 5%. Market dearer—demand heavy; further advance anticipated.
Amidol	9s. lb.
Acetaniline	1s. 5d. lb. Small demand.
Amidopyrine	12s. 6d. to 13s. lb.
Ammonium Benzoate	2s. 6d. to 3s. lb., according to quantity.
Ammonium Sulphocyanide, recryst.	2s. 6d. lb. Cheaper qualities are available at 1s. 9d.
Barbitone	12s. 6d. lb. Dearer.
Benzaldehyde free from Chlorine	3s. lb. Cheaper.
Benzonaphthol	5s. lb.
Bromides	Potassium 7d., Sodium 8d., Ammonium 9d.
Calcium Lactate	2s. lb. for British made products.
Chloral Hydrate	4s. lb. for duty paid.
Formaldehyde, 40%	90s. to 100s. cwt. Supplies not plentiful.
Guaiacol Carbonate	8s. lb.
Hexamine	3s. 6d. lb. Price steadily advancing.
Homatropine Hydrobromide	30s. per oz.
Iron Ammonium Citrate	No change. Rather quiet with small demand.
,, ,, ,,	B.P. 2s. 5d. lb.
,, ,, ,,	Green 3s. 1d. lb.
Iron Perchloride	22s. to 25s. cwt. Steady market.
Menthol	38s. 6d. lb., less 2½% for original cases. Smaller quantities 39s. lb. nett.
Methyl Salicylate	2s. 2d. lb. for water white in glass containers. Drums and tins slightly less.
Methyl Sulphonal	13s. lb. Little inquiry.
Mercurials	Unchanged; rather dull market.
Paraformaldehyde	3s. lb.
Paraldehyde	1s. 5d. to 1s. 9d. lb., according to packing and holder.
Phenacetin	5s. lb. Firmer.
Phenazone	7s. lb.
Phenolphthalein	5s. 3d. lb.
Potassium Bitartrate 99/100% (Cream of Tartar)	98s. per cwt. for ton lots, less 2½%. Firm with upward tendency.
Potassium Metabisulphite	8d. lb.
Potassium Permanganate	8½d. lb. Quotations tending higher.
Quinine Sulphate	2s. 3d. to 2s. 4d. oz. Bulk packages. Fairly steady market.
Resorcin	5s. 6d. lb.
Salol	2s. lb.
Silver Nitrate	1s. 11d. oz. in 500 oz. lots.
Sodium Benzoate	2s. lb. spot.
Sodium Hyposulphite, Photographic	£15 to £17 per ton, according to quantity.
Sodium Potassium Tartrate (Rochelle Salt)	80s. to 85s. cwt. Fair demand.
Sodium Salicylate	1s. 9d. to 2s. lb. Market very firm and rising.
Sodium Sulphite, Anhydrous	£27 10s. to £28 10s., according to quantity, f.o.r. London drums included.
Sodium Sulphite Crystals	£17 to £17 10s. per ton, according to quantity. 1 cwt. kegs included.
Thymol	17s. to 19s. lb., according to quality.

PERFUMERY CHEMICALS

Amongst perfumery chemicals Rhodinol has fallen appreciably in price; otherwise there are no changes to report:—

Amyl Acetate	2s. 3d. per lb.
Amyl Butyrate	8s. ,,
Amyl Salicylate	3s. 3d. ,,
Anethol, melting point 21-22° C.	4s. 6d. ,,
Benzyl Acetate from Chlorine free Benzyl Alcohol	3s. ,,
Benzyl Alcohol free from Chlorine	3s. ,,
Benzaldehyde free from Chlorine	3s. ,,
Benzyl Benzoate, 19.5° C.	3s. ,,

Cinnamic Aldehyde, 98/100%	
Natural	14s. 9d. per lb.
Citronellol	22s. 6d. ,,
Citral, 100%	10s. 6d. ,,
Ethyl Phthalate	4s. 6d. ,,
Eugenol, 100%	10s. 6d. ,,
Geraniol (from Palmarosa)	32s. 6d. ,,
Geraniol	5s. 6d. to 12s. 6d. per lb.
Iso Eugenol	16s. per lb.
Linalol ex Bois de Rose ..	21s. ,,
Linalyl Acetate	22s. 6d. ,,
Methyl Benzoate	8s. 6d. ,,
Phenyl Ethyl Acetate ..	10s. ..
Phenyl Ethyl Alcohol ..	17s. 6d. ..
Rhodinol	45s. ,,
Terpineol	3s. ..

ESSENTIAL OILS

Anise Oil, Red Ship Brand	2s. 1½d.
Bourbon Geranium Oil ..	20s. for shipment.
Cananga Oil, Java ..	9s., firm.
Cinnamon Oil, leaf ..	4¼d. per oz.
Cassia Oil, 80/85% ..	8s. 7½d.
Citronella Oil, Java, 85-90%	3s. 6d.
Citronella Oil, Ceylon ..	2s. 8d.
Clove Oil	7s. 3d.
Eucalyptus Oil, 70/75% ..	1s. 10d.
Lavender Oil, Mont Blanc, 38/40%	14s.
Lemon Oil, spot	2s. 10d. New crop for shipment, 2s. 7d.
Orange Oil, Sweet, spot ..	9s. New crop for shipment, 7s. 9d.
Otto of Rose—	
Anatolian	24s.
Bulgarian	28s.
Palma Rosa Oil	17s.
Peppermint Oil—	
English, Mitcham ..	80s.
Wayne County	13s. 6d.
Japanese	7s. 6d.

TRADE NOTES

Wages in the Soap Trade

As a result of the intervention of the chairman of the Soap and Candle Trades Employers' Federation, the men at the soap and candle works of Messrs. J. and J. Fields, Lambeth, who have been out on strike nearly a fortnight, returned to work on January 19. A reduction of the standard rate of wages in the soap and candle trade was put into force on January 1, and the men at Messrs. Fields are working at the new rate. Certain other grievances will be inquired into when normal work has been resumed.

The Beet-Sugar Industry in Manchuria

About 9000 acres has been planted to sugar-beet in Manchuria this year and an excellent crop, about 50 per cent. greater than that of last season, is expected. The area under cultivation will probably be greatly extended next year. The South Manchuria Sugar Refining Co., of Mukden, which now proposes to obtain beet-seed locally, instead of from Germany and the United States, is erecting a second factory at Tiehling to commence operations at the end of this year. Beet-growers have been paid about 17s. 10d. per ton of roots, a price higher than that paid in Northern Japan, and as coal and labour are also cheaper, the outlook of the industry is promising.

Mineral Production in Formosa

The minerals produced in Formosa include gold, silver, copper, coal, petroleum, and iron ore. Little more than a third of the island has been surveyed geologically, but it is believed that the mountains in the interior are rich in minerals; and the completion of a hydro-electric plant at Jitsugetsutan (Lake Candidius) will make cheap power available in abundance for mining operations in any part of the island. The mineral output in 1920 and 1921 was as follows:—

		1920.	1921.
Gold	oz.	18,687 ..	28,455
Silver	,,	18,086 ..	26,525
Copper	lb.	1,584,000 ..	2,640,000
Coal	tons	1,140,000 ..	1,100,000
Sulphur	lb.	1,848.000 ..	1,861.200
Magnetic iron sand ..	,,	— ..	40,920

The commercial development of the more inaccessible regions of Formosa will probably begin within a few years.—(*U.S. Com. Rep., Dec.* 11, 1923.)

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, FEBRUARY 2, 1923 No. 5

EDITORIAL

ONE of our correspondents asks us to publish a pleasant and easy account of X-ray spectra written in simple language such as ordinary people use. He thinks that an article of this sort would help us all to understand the significance of the new element. We are in entire agreement with him and so soon as we can obtain from those who have been at work on the X-ray spectra of Hafnium and the rare earths, an accurate and authoritative account of the recent investigations we will take the necessary steps. To write in simple language the modern chemical discoveries is not so difficult as is commonly supposed, but it takes time. An expert who has devoted some years to the technical details of X-ray analysis or the ordinary spectroscope can very easily summarise some new piece of work, and he can do this with an accuracy and an insight which no one else can emulate. But he most naturally and quickly does it in the phraseology to which he is accustomed, and this is usually technical. If you call upon him, as he writes, to explain the meaning of Angstrom units, atomic numbers, Balmer series, Bohr's theory and $L\beta_3$ lines, you take up so much of his precious time that he does not readily respond to an invitation. And if one who is not an expert in this branch attempts to write on it, so many papers have to be referred to in back numbers of the *Philosophical Magazine* and the *Comptes Rendus* that much time is involved. In either case it is difficult to arrange, within a few days of the announcement of the new element, for an adequate account of the investigation suitable for a body of readers who differ widely in their tastes and information. We will bear our correspondent's suggestion in mind and if one of our physical chemists will favour us with such an article we, and our readers, will be greatly obliged.

* * *

The chorus of praise resounding the world over in celebration of the centenary of the birth of Pasteur, has not yet attained its height and Dr. Pasteur Vallery-Radot is to lecture on his grandfather's life and work in London on February 2. Now there comes another centenary, one that should be a source of especial pride to Englishmen. We refer to the centenary of the death of Edward Jenner, the discoverer of vaccination. To those of the younger generations the importance of this discovery may seem remote, and such is the confidence in the safety which its application has brought about that detractors of its value are not lacking. It is not our function to point out the folly of our national weakness for allowing sentiment to obscure the interpretation of fact; the recent outbreak of smallpox is sufficient evidence that the increasing avoidance of vaccination is not to be ignored. Jenner's work in founding the science of serotherapy is sufficient claim on the interest of chemists, for the consequences of his discovery range from the protection of vast armies in the field from epidemic disease to preventive inoculations against the winter "colds" that distress the populace. On the foundation thus laid in a Gloucestershire village has been built up the science of serotherapy, equipped with a formidable terminology, bristling with words like "antibodies," "complement fixers," "amboceptors," and the like. The bulk of the work has been done by medical and veterinary investigators, although the problems of serotherapy are fundamentally chemical problems, being concerned primarily with the investigation of reactions between protein matter. There could be no more suitable occasion than the centenary of the birth of Edward Jenner to put forward the plea for co-operation between the chemical and biological sciences, for real progress will be made only when it is realised that chemical research is not merely a means of increasing material prosperity, but touches the basis of life itself. As an instance of the necessity for co-operation between chemists and biologists—a co-operation that should have beneficial results in producing a clarification of the terminology—mention may be made of a recent discussion on fermentation, in which the "education" of bacteria was mentioned, whereas what was meant was merely the elimination from a mixed population of individuals not possessing the desired qualities.

The identification of micro-organisms is not work for the chemist ; nor should the biologist be occupied with the study of purely fermentative processes.

* * *

Our correspondent R.C., whose letter appears in this issue, thinks this journal should not include articles on pure chemistry and we think a little explanation may interest him and many other readers. The journal, including Transactions and Abstracts, goes to all members of the Society of Chemical Industry. Chemistry and Industry, without the Transactions and Abstracts, with the assistance of the Chemical Society, goes to several hundred Fellows of the Chemical Society ; it also is sent to a number of other subscribers and is on sale at a large number of railway bookstalls as appears in the advertisement in this issue. The Chemical Society, the Society of Chemical Industry, the Federal Council and several other Societies attach great importance to this co-operation, and it is perhaps a first step in a more far-reaching form of co-operation to be considered in the future. In a journal circulating among a considerable number of readers who are not all concerned in applied chemistry, a great variety of topics must be discussed. Some of these readers have a considerable knowledge of both pure and applied chemistry, some have a fund of information on one branch only, many have very little exact knowledge of chemistry, but are interested in the subject. We are therefore compelled not only to deal with pure chemistry as well as applied, but we shall have to publish articles which are very elementary indeed, bringing in facts which are well known to all those who have ever studied chemistry. If a reader finds sometimes an article which mentions no fact new to him, let him remember that there are others who are not so fortunate.

* * *

A detailed and critical examination is being made of the suggestions which we receive in connexion with this journal, and we are convinced that in a few months we shall find out what sections of the public it will appeal to, and how we can best satisfy them. If a reader finds that some sort of article is lacking, the best criticism is to send us an article of the type desired ; we shall take this as a hint and act upon it. To those, if any, who are dissatisfied with our progress, we must plead that if we are spared for a while we shall grow in substance and flavour. *Laissez-moi carpe devenir.* It takes more than a few weeks to build up an organisation. That part which deals merely with correspondence and proof-correcting is soon established ; it is a longer process to discover what the readers wish to read, and still longer to find which of our readers will write what is desired. Our readers are the only source of supply, and when the organisation is complete it will be found to be a co-operative society.

CHINA CLAY

Its Composition, Preparation and Uses

By H. F. COLLINS, A.R.S.M., M.I.M.M.

NEXT after coal (although a long way after) china clay or kaolin is the most important raw material that the United Kingdom is in a position to export. In view, therefore, of the trade balance against this country, and of the growing difficulty experienced in finding markets for our manufactured products in competition with those of other countries, the export of china clay, both from the point of view of output and of return freight, possesses an importance greater than would be suggested by a consideration merely of its intrinsic value per ton.

The china clay of commerce is not quite a raw material, but a purified and partially prepared one, since it is not found naturally in precisely the same form in which it is sold. Unlike the ball clays of Devonshire and Dorsetshire, which are of detrital origin, and are sold as dug. china clay is the product of the decomposition *in situ* of the felspathic constituent of granitic rocks, which in certain places have been converted into a soft crumbly material that upon soaking in water becomes pasty ; and in order to separate the clay from the other constituents of the rock (quartz and mica, with smaller quantities of tourmaline and other minerals), this must be disintegrated and the clay washed out by a stream of water, from which it is recovered by settling. The process is closely analogous to that by which nature herself produced detrital clays, only, being strictly under control as regards the material washed, the volume of water employed, and the impurities eliminated, the product is very much more uniform in respect of grain, colour, and composition, than any natural detrital clay can possibly be.

COMPOSITION

China clay is a white impalpable powder, which when kneaded with water forms a paste much whiter, although less plastic and tenacious, than common pipe- or ball-clay. Upon drying, the paste forms cakes or lumps of little coherence but of uniformly smooth and even texture, and powdery rather than greasy to the touch, although free from all grittiness.

In composition kaolin is a hydrated silicate of alumina, but although presumed to consist chiefly of the mineral kaolinite, it varies considerably in composition. The formula of kaolinite according to Dana is Al_2O_3, $2SiO_2$, $2H_2O$, which calls for 46·6 per cent. SiO_2, 39·5 per cent. Al_2O_3 and 13·9 per cent. H_2O. The composition of a large number of clays agrees fairly closely with this formula, as is shown by the following analyses, all of average samples of well-known brands of clay, dried at 100° C.

	1	2	3	4	5	6*
SiO_2 (and traces of TiO_2) ..	47·23	46·2	45·4	48·38	46·69	46·90
Al_2O_3	39·49	41·1	40·3	36·99	38·34	40·89
Fe_2O_3	0·23	0·1	0·2	0·62	0·45	0·14
CaO	0·31	tr.	tr.	0·15	0·33	0·13
MgO	0·24	0·2	tr.	tr.	0·10	0·08
Alkalis (calc. as K_2O) ..	0·21	0·4	0·6	0·29	1·42	0·58
Water	12·24	12·5	13·5	13·57	12·56	10·50
	99·95	100·50	100·00	100·00	99·89	99·22

* Average of four samples dried in vacuo over sulphuric acid.

It is, however, improbable that the composition of china clay is anything like so simple as would be indicated by the above formula. In the first place it seems likely that the alumina occurs combined in two different ways, for when clays are treated with hot H_2SO_4 about one-half of the alumina content dissolves out at once as sulphate, whilst the remainder only becomes soluble after long digestion with concentrated acid. In the second place nearly all clay contains a small amount of finely divided free silica (quartz), which resists alike boiling with H_2SO_4 and subsequent digestion of the residue with dilute Na_2CO_3. Further, as shown long ago by J. H. Collins*, when china clay is dried for long periods in vacuo over sulphuric acid, its combined water content is reduced uniformly to about 10·5 per cent. Column 6 in the foregoing table of analyses is the mean of samples of clay so treated and analysed by him. There are, moreover, certain exceptional clays that are much lower in silica and higher in alumina content than the typical varieties shown in the above analyses: these probably contain halloysite, allophane, or some similar mineral, in addition to the normal kaolin.

Distribution

China clay being a product of the decomposition *in situ* of the felspar of granitic rocks, it is at first sight curious that its distribution should be so extremely local. No workable deposit of china clay has been hitherto found in all the extensive granitic areas that cover so large an extent of country in Scotland and Ireland, and in the British Isles its occurrence is confined almost exclusively to the West of England, whilst even there, outside the granitic boss of the St. Austell district, it is only exceptionally found. The largest of the West of England granitic masses, that of Dartmoor, has thus far yielded china clay only towards its south-western extremity. Those of the Land's End—St. Ives area and of Wendron have shown china clay only at one or two points. In the St. Austell district alone do deposits of clay become relatively common, the number of those already known running up to nearly a hundred. These facts alone dispose of the hypothesis advanced by some that the decomposition of the granite has been effected by some surface agency, such as carbonic or humic acid, and render it certain that the alteration has been effected by solutions from below. The deposits themselves are rarely basin-shaped, nor do they cut out at shallow depths; on the contrary, they take the form of dykes or pipes, the depth being far greater than the breadth, and even when of great width, the depth is usually in proportion. No case is known in which a true dyke- or pipe-shaped deposit of china clay has "cut out" in depth, although many of those of small size have become unprofitable to work at depth, in consequence of the large amount of barren overburden, which has to be removed at the sides of the excavation as the depth of this increases. Close examination of every known deposit of china-clay ground shows that it is associated either with a single group of parallel fissure veins (the dyke-shaped deposits) or with two or more groups intersecting at an angle (pipe-shaped deposits). These veins vary in size from a fraction of an inch up to many feet; the principal filling is quartz, with which are associated schorl or black tourmaline, muscovite, gilbertite and other micas, and more rarely topaz, cassiterite, etc. It is noteworthy that the proportion of cassiterite has in several cases been sufficient to justify working the deposits for tin. Carclaze, for instance, the largest of the Cornish pits, was worked for tin considerably more than a century ago, long before the clay contents of the deposit were recognised as having any commercial value.

In nearly all cases it is noticeable :—

(1) That the greatest length of the deposit of "clayrock" corresponds with the direction of the principal group of fissures.

(2) That the decomposition of the granitic felspar is most complete in close proximity to the fissures, dying away gradually at a distance therefrom. In some cases, the decomposition appears to be confined to the section of ground lying between two parallel groups of fissures.

From these facts, it is impossible to avoid the conclusion that the fissures themselves have been channels through which the circulation of solutions (or vapours) from below has been effected. It is, however, by no means the case that the largest fissures have given rise to the greatest extent of decomposition; possibly, indeed, those veins which are the largest, and show the greatest development of quartz, may have been responsible for a comparatively small amount of decomposition in the surrounding rock, precisely on account of their rapid sealing up through the deposition of so large an amount of quartz.

As to the mineralising or decomposing agent, in view of the large amount of free silica introduced and deposited, it can hardly have been an alkaline solution. Neither is it likely to have been solutions or vapours carrying free carbonic or sulphuric acids, for carbonate and sulphate minerals are conspicuous by their absence. The comparative abundance of tourmaline and gilbertite (both of which contain fluorine in variable proportions), as an essential constituent of the altered rock indicates hydrofluoric acid as a possible agent, and experiments by the late J. H. Collins more than 30 years ago, demonstrated that it was possible to produce kaolin or china clay, undistinguishable in composition and properties from that found in the natural deposits, by exposing orthoclase felspar to vapours or dilute solutions of hydrofluoric acid for a long period at ordinary temperatures. At an elevated temperature the action would doubtless be much more rapid.

---

* Mineralogical Magazine, Vol. VII., 1886, p. 209.

It may be assumed, therefore, without reasonable doubt, that hydrofluoric acid in solution or vapour was the agent that effected the decomposition of the West of England granites, and produced the china-clay. Not all of the felspar is equally affected. Large porphyritic crystals, when present, appear to resist decomposition after the whole of the smaller crystals forming the base have been altered ; since the latter includes the whole of the comparatively small amount of plagioclase present (chiefly albite or albite-oligoclase), it seems possible that plagioclase may be more readily affected than orthoclase.

Occasionally the veins carry some iron oxide, and in such cases the colour of the clay may be completely spoiled in their proximity. Usually, however, it is the very finest and whitest clay that is found between the veins and stringers. The proportion of clay in the ground worked depends of course upon the proportion of felspar in the original granite, and may vary from as low as 10 to 12 per cent. up to 30 and even 40 per cent. Usually it is the leanest ground which yields the best class of clay, *i,e.*, the whitest ; in " fat " ground, containing a high proportion of clay to sand and waste, the colour of the clay is often inferior, and the quality rarely better than common to medium. In the case of many pits that yield a comparatively low proportion of clay to the total ground worked, either on account of the inordinate proportion of quartz stringers (*e.g.*, Dorothy Pit), or to a low proportion of felspar in the original granite mixture (*e.g.*, Trethosa Pit), or finally, in consequence of the fact that only part of the felspar has been decomposed, much remaining still unaltered (*e.g.*, Lee Moor Pits), the comparatively poor yield is more than offset by the exceptionally high quality, namely, the pure white colour and extra fine grain.

The deposits of valuable clay are always overlain by a certain extent of " overburden " or worthless ground, that must be excavated and removed before the clay ground itself can be worked. This consists generally of surface soil or peat, and sand and gravel, with boulders of granite ; sometimes, too, of clay ground that is so discoloured as to be worthless. The total depth of worthless ground of these various kinds to be removed is rarely less than 6 or 8 feet, and may run up to 60 feet, although this is an extreme figure, a more usual one being 15 to 20 feet.

METHOD OF WORKING

The washing out of the clay from the " sand " and waste rock is always done *in situ* by a stream of water, which carries with it only the clay and the finest waste, the coarse sand and larger waste being raised from the bottom of the more or less funnel-shaped pit, usually by means of waggons running up an incline, and automatically tipped at surface on what are called " sky tips." If situated upon a hillside or upon high ground not too far from a deep valley, the cheapest way to open up a clay deposit is by means of an adit, below which are placed all the settling and drying arrangements so as to avoid the necessity for pumping the clay stream. If sufficient fall is available, the adit may be run upon a grade steep enough for the stream of water to carry with it not only the clay but the sand also, in which case hoisting of the sand is also obviated, as at Old Lee Moor. When the fall is insufficient for this, the adit carries away only the clay stream itself, and the sand is raised from the pit by means of self-tipping waggons running upon an incline, as at New Lee Moor and Carclaze.

Disintegration of the clay ground and washing out the clay from the other constituents is performed in two ways. In the more primitive but still largely used method, a stream of water running over the clay ground exposed in the pit cuts a shallow gully or " strake," the sides of which are continually broken down into the stream by mattocks and hoes. In the more modern method, the water is carried down the pit in pipes, and discharged at the bank of clay ground from a nozzle of $1\frac{1}{4}$ in. or $1\frac{1}{2}$ in. diameter under a natural head (aided when necessary by pumps) of 60 to 100 lb. per square inch. Even in this case, a certain amount of hand labour is requisite to keep up the clay content of the stream to be pumped, particularly when the ground is " lean." The hydraulic method is especially suitable to " fat " and uniform ground ; the " strake " method of washing, however, affords facilities for picking out streaks and pockets of discoloured ground, which, if allowed to mix with the rest, would spoil the colour of the clay, and therefore lower its quality for market. Many producers of " best " and " high medium " clays therefore adhere to this method, in spite of slightly higher labour costs, on account of the facility for keeping up the grade of the best clay by picking out discoloured portions of ground for separate washing to yield " seconds."

The stream of mixed clay and sand resulting from the disintegration of the clay ground flows to the lowest point of the pit, whence, in some cases, clay and sand are raised together by means of gravel pumps, a square box grating round the suction of which serves to keep back all but very small stones. The delivery of the gravel pump is into large wooden boxes with hopper bottoms, in which the sand settles, the clay stream overflowing to the purifying plant.

The wear and tear upon gravel pumps is, however, considerable, whilst the pumping itself is neither so efficient, so capable of ready adjustment. nor so entirely reliable as that effected by ordinary plunger pumps. The more usual method of pumping, is therefore, by Cornish plunger pumps and pitwork, worked either by Cornish engines or by horizontal engines actuating balanced lifts. In this system, in order to reduce to a minimum the wear and tear, it is necessary to pump clay-water carrying only the finest sand and mica. The coarse sand is, therefore, first separated at the bottom of the pit in shallow "sand pits" with fronts of wooden slats, which are raised successively as the sand accumulates, to be subsequently shovelled out into tip-waggons running upon an incline and raised to the sky-tip at surface, whilst the clay water overflows and runs to the pumps.

On arriving at the surface, the clay water is split into several streams, and run through several series of shallow channels called "drags" and "micas," in which are deposited first the finest sand and secondly the flakes of mica and grains of coarse, imperfectly disintegrated clay. The purified clay is then settled in "pits" (usually circular) and stored in "tanks" (usually rectangular), in which it accumulates, acquiring the consistency of a thick "slurry" with from 45 to 55 per cent. of water and sometimes more.

This is trammed in wooden tip-waggons to the "dry," composed of a floor of fire brick slabs or "tiles," upon which the clay is spread in a layer from 12 to 5 in. thick, heated by means of the hot gases from coal fires which pass slowly underneath them.

In the case of many works situated close to a good road or a railway, the settled clay is transferred direct from the settling "pits" to the storage tanks behind the dry, situated at a lower level, by simply opening a "hatch" and pushing out the half liquid mass with the aid of a small stream of water. Often, however, particularly when the clay pits are situated high on the moors, and at some distance from the railway or from the shipping port, it is preferred to transfer the clay in earthenware pipes for a distance of from two to six miles from the settling pits to tanks and drys situated close to a railway or port.

For further details in connexion with the settling and drying of china-clay the reader is referred to a monograph on the subject published in the *Mining Magazine* for the months of November, 1919, to February, 1920, wherein reference is made particularly to the question of economy in drying.

(*To be continued*)

LEGISLATIVE AND DEPARTMENTAL INTERFERENCE WITH INDUSTRY AND THE COMMON WEAL.

By PROF. H. E. ARMSTRONG, F.R.S.

(*Continued*)

British employers were guilty of pure Quixotism. The Canadian representative was bitterly opposed to the action taken and the Australian delegates were all against it, though they agreed to fall into line with the others.

The terms of the Convention must be ratified by Governments to make them binding and it is clear that the time is past for such ratification in this country. As I have said, the agreement was made without consulting public interests. Lead paint is proved and known to be superior to all other paints as a protecting film. Not only have the dangers arising from its use been exaggerated and effects attributed to the lead which are due to volatile liquids used in thinning paint ; what is of far greater importance, the real source of danger, the dust produced in rubbing down, can now be entirely obviated. This had been established shortly before we left for Geneva by Mr. C. A. Klein, with whom I have had the privilege of working during the past dozen years. His constructive work has been of the greatest service to the industry. He first showed that ordinary sandpaper could be used wet. In the interval, a waterproof paper has been produced which seems even to improve with use. It is found not only to be feasible to rub down painted surfaces, before putting on a fresh coat, without producing dust ; such a method is admitted even to have advantages. So much is this the case, that recently regulations have been prepared by the Home Office, in collaboration with the Painters' and Decorators Industrial Joint Council of Great Britain, in one of which it is provided that "surfaces painted with lead paint shall not be rubbed down or scraped by a dry process."

Apart from sheer carelessness, the dangers to painters from lead, in future, will be nil. What they will most need to guard against will be the vapours given off from the volatile thinners, which are a necessary component of all paints : yet, of set purpose, at Geneva, the discussion of this danger was made taboo.

Such are the uses of adversity. It has compelled careful study of the problems and, fortunately, the element of imagination has been brought in and a constructive solution found.

ANTHRAX

Brief reference may be made here to the peculiar use our English Government sought to make of the International Labour Conference at Geneva, to secure the general disinfection of wool and hair infected with the anthrax organism, a well recognised and serious danger to those using wools of a certain class. As I took the place of the

Australian Employers' delegate on the Committee, I can speak with intimate knowledge of the proceedings, which were an extraordinary contrast to those of the White Lead Committee, which I also sat through.

In 1919, an Act was passed prohibiting the importation of anthrax-infected wools into this country. A Departmental (Home Office) Committee had studied the subject, not only with great care, but had taken the unusual step of dealing with the problem constructively. Mr. Duckering, one of the Departmental Inspectors, had devised and worked out, in all details, an entirely satisfactory, economic, disinfecting process. When it was found that the Act could not be enforced and that the incriminated wools were simply being diverted to other markets, to comply with the Act, a small factory was set up in Liverpool, to deal with the wools in bond. Our Government, instead of developing this enterprise into a commercial organisation in the hands of the trade, seeking as it were to unload their responsibility and the commercial burden upon the exporting countries, endeavoured to use the Geneva machinery to make disinfection generally compulsory. The committee of 24 was fortunate in having a most admirable chairman in Mr. Ribbing, a Swede. His most able report is printed in the Conference proceedings.

It was at once clear that the English proposal had no supporters. No attempt had been made, in advance, to consult with the representatives of India or the Dominions. Owing to the great length of the Indian frontier and for other reasons, it was impossible for India to contemplate compulsory disinfection. The problem was debated most thoroughly, without heat, though it involved much smoothing out of opinion; the labour delegates, in particular, were most reasonable. Ultimately the 23 members present were unanimous in agreeing with the Report; when brought before the Conference, this was accepted without a word of remark or discussion. The wise decision was taken to refer the matter to an International Committee for further discussion and report; this should have been our original proposal.

In my opinion, the proceedings of the Committee may well serve as a model for future Conferences, whilst those of the White Lead Committee and the subsequent proceedings in open Conference show what is to be avoided.

SAFEGUARDING OF INDUSTRIES ACT

This unhappy Act is, perhaps, the most striking and unfortunate exemplification of Departmental inability to face problems involving scientific issues. Everyone is acquainted with its farcical clause and the still more farcical lists which are based upon this. It is open to question, whether the terms of the Act justify any such lists. Certain it is, that the chief, if not the only gainers, by the Act are members of the legal fraternity. Be that as it may, what we chemists have to deplore and protest against, must protest against until remedy be found, is the shameful way in which the traditions of our craft are being mishandled. It is obvious that the Referee, as well as the Counsel engaged in the various hearings, are without feeling on the subjects argued about and mere dialecticians. What would the lawyers say if we were to presume to argue and determine knotty legal cases, involving profound knowledge of legal procedure and precedent? At least, they would demand that we should sit with legal assessors. The Referee appears but to count heads—to him a chemist is a chemist, his wholeness being no element in the case. Some of the evidence given has been most misleading. At least we should demand of the Board of Trade, nay insist, *that no further cases shall be heard* until scientific assessors are appointed to sit with the Referee.

The decision, in the opening case, in which it was ruled that calcium carbide was not a synthetic organic chemical, was against every canon of chemical belief. As early as 1854, our pioneer chemical systematist, Laurent, saw the importance of defining the term organic, in his great work on *Chemical Method*. In the chapter on "The functions fulfilled by simple bodies in organic substances," he writes:—

> We maintain for our part, that an organic substance is simply a substance containing carbon: thus marble, cyanogen, carbonic oxide, sulphide of carbon, chlorocarbonic acid, etc., are organic substances.

Since then every chemist able to envisage our science has followed this precedent.

THE DYESTUFF ACT

However unfortunate the action of the Board of Trade in mis-handling the Safeguarding of Industries Act, its attitude towards the Dyestuffs Industry has been far worse: it may well be said to have been its evil genius from the beginning. The position could not have been worse, had there been no Government subsidy. Up to the moment, we have not realised what are the conditions under which alone such an industry can be recreated, in this country: that its management *must* be in the hands of technically qualified persons, able to sympathise with and so hold intelligent communication with its staff; knowing, without explanation, the needs, the difficulties, the possibilities of the situation.

My attitude is not determined either by commercial considerations or by thought of future war—though I have both in mind. My object in advocating the firm establishment of the Fine Chemical and Dyestuffs Industries is of a different order: pride of race influences me most. We know we are as good players at Chemistry as those of our own class in Germany. The Germans, however, *say* the contrary, whatever they may think. As one of the team, I know that if I do not practice and, in fact, soon win, I shall be forced to give way to better players. I ask for the opportunity of practice during a fair time, My difficulty is the Board of Trade doesn't allow me and puts me under impossible conditions: it will not give me proper trainers and the example it thus sets acts against me everywhere; and so it is with all concerned.

Sir Alfred Mond, with characteristic clear-sightedness, saw the position and asked for proper inquiry into the working of the two Acts. As he said, the whole administration of the Key Industries Act requires overhauling; and this is equally true of the dyestuffs position.

Instead, the Board of Trade and the Department of Scientific and Industrial Research is to inquire. The one is the incriminated Department; the other is incompetent to do any such work. Sir Alfred Mond's is the only solution of the problem.

Original Inquiry and Research

The Departmental interferences to which I have referred, I am sure, have always been exercised with those good intentions with which a certain well known and much favoured resort is paved; they are due to an inherited, constitutional disability, usually reinforced by an Oxford training, to live up to the times—to recognise that a new method is in use, the world over, that which we call scientific; a method which is based upon observation, trial and experiment, not upon mere precedent and illogical discussion.

We are now threatened, in addition, with something far worse than an impassive wall which we cannot surmount. By a carefully calculated and premeditated attempt, our position of freedom as scientific workers and artists is being undermined and must be lost to us if we do not soon rise up in revolt. The Royal Society has been displaced and the position it should occupy taken over by a purely bureaucratic organisation, mainly influenced by literary men knowing nothing of our method. Its incompetence is shown by the way in which it has allowed its Fuel Research Board to spend large sums of money without submitting its scheme of action to competent criticism and to the interests concerned, in order to benefit by their approval, experience, and support. In various ways it is interfering with the free course of development of the art of scientific inquiry; we are being red-taped in every direction. To place painters, sculptors or poets in leading strings is known to be impossible: scientific inquirers we know belong to the same class as these, they are just as vagrant and sensitive: to curb and check their imagination is fatal. We must be masters in our own field. A false idea of the nature of scientific inquiry is growing up—mere students exercises are being dignified and paid for as Research, and soon the term will signify merely the act of repeating what some other fellow has already done—probably better. There must be a protest against such abuse.

The new Department should be included in Sir Alfred Mond's inquiries.

I began on a federal note. Let me end by striking one of higher range. My call to you is to take an active part in the battle of life, to show that you are not mere laboratory parasites but men of affairs; that you are alert watchers, ready at any moment to protect public interests. Difficult and hard times are before us and we must pull together to get through. If chemists unite in the Federal Council their example will influence those devoted to other subjects. Industry now recognises the importance of cultivating relations with science as well as with the public. Science is not yet so broad-minded—at least in its higher spheres. The respectable society I once frequented is now too dull to visit. The Royal Society is losing its public influence in every direction. In my young days, men like Faraday, Darwin, Playfair, Huxley, Tyndall, not forgetting the artist, naturalist, and geologist, Ruskin, addressed themselves to the public and were heard. To-day there is no one who has any public message to deliver. Sensational discoveries and inventions are talked of but there is no influence at work to maintain the ethical standards so prominently held up by the men I have mentioned. During years past, I have urged that the Royal Society should be organised as a scientific House of Peers, commanding the respect of the nation, critical of all things done in the name of science and willing to advise to the best of its power. If science is to live, some such step must be taken: otherwise it must be entirely commercialised. A vast incubus of inertia has to be overcome: we are too much wedded to one course of action. In Ruskin's words :—

> What strength of faith men have in each other; and how impossible it is for them to be independent in thought, however hard they try. Not that they ever ought to be; but they should know, better then they do, the incumbrance that the false notion of others is to them.

Our fault is a too entirely, if not selfish, devotion to our work: we mistake this for zeal.

It is written, "But a multitude of wise men is salvation to the world." Yes it is—provided always their wisdom be fluent. You know, Government tells you daily, that *your* wisdom is not asked for. You will, therefore, needs force it into use and will seek to do so, if you have any sense of your worth.

Here ends my hasted address. It is clear that "the bowsprit gets mixed with the rudder sometimes," even in ordinary life. Some printer's devil or sprite has put the slips in strange order and his ultimate section was the first; that on the Federal Council and a Palace of Chemistry came next, preceding that on milk.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

WHICH IS THE OUTSTANDING DISCOVERY ?

I asked last week and some of my readers have hastened to reply. There will not be space sufficient for me to comment on all the replies I have received, but some of them are most interesting reading. One of my correspondents, reviewing the past thirty years, gives pride of place to Madame Curie's discovery of radium on the ground that not only was it altogether novel and epoch-making in itself, but as a logical outcome of the investigation of its properties an entirely new conception of atomic structure has been evolved. To the ordered mind of the chemist the classification of the elements according to Mendeleef's periodic system came near to the ideal—the discovery of the radioactive elements has filled many gaps in the system. Radium—X-rays—α-particles—electrons, in the hands of such brilliant experimenters as Crookes, J. J. Thompson and Rutherford, are all stages in the inquiries which have led us very near to the limit of the knowable as regards the structure of the atom. As the ultimate aim of chemical science is the how and the why of everything, such basic discoveries cannot be surpassed in importance, and looking back it is little short of marvellous in what brief space of time they have been accomplished. The recognition of isotopes is again but a logical extension of the discovery of radium.

ANOTHER CORRESPONDENT TELLS ME

that my question would have been easier had I asked: "Which were the two outstanding discoveries of the past thirty years ?" He points out that two entirely separate lines of inquiry started within this period blended together to give us our present knowledge of the structure of chemical elements. In 1894 Rayleigh and Ramsay discovered argon, a gas which had probably been isolated, although not specifically defined, by the quantitative experiments of Henry Cavendish about a hundred years previously. The isolation of an entirely new form of matter, devoid of chemical properties, led Ramsay to look for argon or similar gases in various minerals. From the uranium mineral, Cleveite, he isolated another inert gas having a characteristic spectrum which showed a yellow line identical with the line noticed in the sun's chromosphere at eclipse and attributed by Norman Lockyer to the presence of a hypothetical element to which the name helium was given. In the gas extracted from Cleveite and other uranium minerals Ramsay had isolated terrestrial helium. In 1896 Henri Becquerel examined the radiations emitted by salts of uranium, which had the property of affecting photographic plates and discharging electroscopes. This investigation was continued systematically by M. and Mme. Curie, who found that pitch-blende possessed considerably more activity than isolated uranium salts, and subsequently they showed that the activity was due to a new element, radium. Further research showed that radium, itself a product of the disintegration of uranium, was also in a state of change. Among the products of the disintegration of radium was discovered helium, so that in this way the two independent lines of research became connected. All of which is very interesting, and I thank my correspondents for the letters they have sent me.

THE POSITION IN THE RUHR

goes from bad to worse, but becomes more defined as the weeks go on. It seems clear that France has a definite policy which she proposes to follow until either she herself is exhausted or Germany will yield to France's demands. At first, one was inclined to think that France had been misled into the belief that Reparations could be obtained by marching into the Ruhr; it now seems possible that she was not misled, but knew full well that she could obtain neither money nor goods, and therefore decided to take a strip of Germany which in time she could make remunerative. The protests from French sources rather confirm us in the opinion that the real object of the operations in the Ruhr is at last disclosed; and, immediately, one tries to estimate the effect on British chemical industry. The trouble has not yet extended so far to the south of the Ruhr as to affect directly many of the works of the Interessengemeinschaft, but already there is difficulty in obtaining supplies from Germany.

WHAT WILL HAPPEN ?

There are also more enquiries for fine chemicals and dyestuffs in this country, and the unfair competition by means of the rate of exchange is lessening. Our own works are likely to be busier, and there should be more opportunities for unemployed graduates in science. There are two pitfalls in the situation which we should do all we can to avoid. If there be an increase in the demands for British chemicals owing to the difficulties in which the Germans find themselves, it will probably be only of a temporary character. The collapse of Germany may, for the moment, lead to an increase in production in this country and a lessening of unemployment, but it will set back the recovery of Europe for many years and the final recovery of this country proportionately. The second pitfall is that our leaders, with the ever insistent demand of their shareholders for dividends in their ears, may be tempted after the lean years to force the rise in prices too high, and that will also retard recovery. Above all we want sane judgment and courageous leading at this juncture.

FORTHCOMING EVENTS

Feb. 5. Society of Chemical Industry, *London Section*, Engineers' Club, Coventry Street, W., at 8 p.m. "The Estimation of Fat in Casein," by G. T. Bray and F. Major. "Explosions in Liquid Air Rectification Plant," by Dr. E. Fyleman.

Feb. 5. A Course of ten lectures on "The Micro-Organic Population of the Soil" will be given by Sir John Russell and staff of the Rothamsted Experimental Station in the lecture theatre, Botanical Department, University College, Gower Street, W.C. 1, at 5 p.m. Also on February 7, 12, 14, 19, 21, 27, and March 1, 5, and 7.

Feb. 7. The Institution of Sanitary Engineers, Caxton Hall, Westminster, S.W. 1, at 8 p.m. "National Water Resources and their Allocation," by Percy Griffith, M.Inst.C.E., F.G.S.

Feb. 7. Royal Society of Arts, John Street, Adelphi, W.C. 2, at 8 p.m. "Electrical Resistance Furnaces and their Uses," by Charles R. Darling, F.Inst.P.

Feb. 8. The Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 3 p.m. "Photo-synthesis of Plant Products," by Prof. I. M. Heilbron.

Feb. 8. Institute of Metals, *London Local Section*, in the Institute of Marine Engineers, 85-88, The Minories, Tower Hill, E. 1, at 8 p.m. "The Investigation of the Constitution of Alloys," by Miss M. L. V. Gayler, M.Sc.

Feb. 8. Society of Chemical Industry, *Ottawa Section*, University Club, Elgin Street, Ottawa, at 8 p.m. "Biochemistry in Relation to the Rearing and Nutrition of the Silver Black Fox," by G. Ennis Smith.

Feb. 9. Society of Chemical Industry, *South Wales Section*, Technical College, Mount Pleasant, Swansea, at 7.15 p.m. "Stainless Steel and its Uses," by H. B. Hitch.

Feb. 9. The Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 9 p.m. "Rothamsted and Agricultural Science," by Sir John Russell.

Feb. 12. The Ceramic Society, Central School of Science and Technology, Stoke-on-Trent, at 7.30 p.m. "Notes on Application of Pyrometers to Ceramic Industries," by Mr. Chas. E. Foster.

Feb. 12. Royal Society of Arts, John Street, Adelphi, W.C. 2, at 8 p.m. "The Vulcanisation of Rubber" (Lecture 2), by Henry P. Stevens, M.A., Ph.D.

Feb. 13. Society of Chemical Industry, *Edinburgh and East of Scotland Section*, the Pharmaceutical Society, 36, York Place, Edinburgh, at 7.30 p.m. "Vitamins," by Dr. G. M. Findlay, M.A.

Feb. 13. Institute of Metals, *Scottish Local Section*, Institution of Engineers and Shipbuilders, 38, Elmbank Crescent, Glasgow, at 7.30 p.m. "Some Phases of Lead Manufacture," by John A. Sillars.

Feb. 14. Royal Society of Arts (Ordinary Meeting), 18, John Street, W.C. 2, at 8 p.m. "Progress in the Manufacture of Refractories," by W. J. Rees, Lecturer on Refractories in the University of Sheffield.

NEWS FROM THE SECTIONS

AMERICAN SECTION

Prof. R. H. McKee presided at the meeting of the American Section held on January 12, when the Perkin Medal was presented to Dr. Milton C. Whitaker for his work in applied chemistry. Mr. A. A. Bachaus gave an account of Dr. Whitaker's work at the Sullivan Saw-Mills, Aztec, New Mexico, and his subsequent career as head of the Chemical Engineering Department at Columbia University.

He was followed by Mr. A. D. Little, whose speech was full of personal humorous touches, and included a description of one of Dr. Whitaker's most important labours—the organisation of a plant for the manufacture of alcohol from molasses, and the production of vinegar and acetone. Dr. Whitaker was chairman of the New York Section of the Society of Chemical Industry in 1911 and President of the American Institute of Chemical Engineers in 1914. From 1915 to 1917 he was President of the Chemists' Club. Mr. Little praised highly the vigour of Dr. Whitaker, both in mind, body and vocabulary.

Dr. Charles F. Chandler presented the medal in the following words: "Dr. Milton C. Whitaker, my dear friend, it gives me the greatest pleasure as the representative of the Society of Chemical Industry and the affiliated Chemical and Electrochemical Societies of America, to place in your hands this beautiful Perkin Medal, as a token of the appreciation and affection of your fellow chemists." Dr. Whitaker, in accepting the medal, stated that he was very appreciative of the distinction which had been conferred upon him; that he had been an organiser rather than an individual worker and that the achievements which had resulted in the award of the Perkin Medal to him, were necessarily therefore achievements of the chemists with whom he had worked.

In dealing with organisation for chemical production, he stated that adequate organisation was a necessary condition to success, and while research chemists and physicists are laying the foundations for products, processes and plants, someone must develop and perfect concurrently a suitable organisation to carry research results through the various stages of development and finally to profitable production. Over-organisation was the most general fault, and in many cases during the war there was so much organisation that there was no one left to do the work. It was difficult to understand why men with a highly specialised technical talent who were surrounded by most fascinating problems, and with important achievements easily within their reach, should have a hankering to do executive work for which in many cases they were quite unsuited. Many research projects were doomed to failure from the very beginning because of the lack of interest or understanding on the part of those in authority. Research was entitled to the support of everyone in the organisation. The research men were often sensitive and temperamental and responded to encouragement and support, whereas discouragement frequently led to disaster. In his experience, so soon as the results of laboratory work were completed, plans were considered for an elaboration of these into a small laboratory apparatus. The co-operation of the engineers was ensured from the very beginning. Their engineers worked with and ranked with their research chemists, and experimental units which permitted of a continuous operation for a long period were soon established to produce a sufficient quantity of the product to enable it to be sold, and determine its market value. These were operated for several months, and enabled the staff to become familiar with the purchase of raw materials, costing, and selling.

He gave some account of the acetone process which supplied 60 per cent. of the war requirements for acetone, and the sudden change in affairs when the Armistice was signed.

Passing on to the production of ethyl acetate, he explained that he was called upon to work large volumes of dilute acetic acid varying in concentration up to 15 per cent., and his first problem was to make a thorough study of the reactions between alcohol and acetic acid, including equilibrium conditions, concentration of catalysts, and various ratios of acetic acid and alcohol. From this, it appeared that there is a very definite reaction between acetic acid and alcohol in dilute solutions. Very dilute sulphuric acid is an excellent and effective catalyst, the rate of re-action is comparatively high, and the old ideas about high concentration of the reacting materials and dehydration were mistaken.

Interesting statistics were given of the property of ethyl acetate to form constant boiling mixtures, and a table of mixtures of ethyl acetate, alcohol and water at various boiling points was given. The monthly production of anhydrous, chemically pure ethyl acetate by the continuous esterification of dilute acetic acid by this process is now over 150,000 gallons.

EDINBURGH AND EAST OF SCOTLAND SECTION

Prior to the informal meeting held on January 16, 1923, the members of the Section were entertained as guests by the Edinburgh University Chemical Society at a meeting held in the Medical Chemistry Department of the University. Professor G. Barger, M.A., F.R.S., presided, and a paper was read on "The Chemistry of the Genus Eucalyptus," by Prof. R. Robinson, D.Sc., F.R.S. A vote of thanks to Prof. Robinson was moved by Mr. R. E. Gibson, President of the Edinburgh University Chemical Society, and seconded by Dr. H. E. Watt, Society of Chemical Industry.

The Fourth Ordinary Meeting of the Section was held subsequently in the Tutorial Class Room, Medical Chemistry Department, Dr. H. E. Watt in the chair. The following papers were read :—(1) "Notes on an Apparatus for the Combustion of a Volatile Hygroscopic Liquid" : Mr. J. B. Shoesmith, M.Sc. (2) "Methods of Emptying Carboys of Strong Acid" : Mr. J. Adam Watson. A discussion followed in which Major Bruce, Messrs. Rutherford Hill and Baxter took part.

GLASGOW SECTION

A Joint Meeting of the Glasgow and Edinburgh Sections was held in the Institute of Engineers and Shipbuilders, Glasgow, on January 19, when Dr. E. F. Armstrong, F.R.S., read a paper on "Chemical Action, Particularly at Solid Surfaces."

In speaking of chemical action, Dr. Armstrong said we all know what it means in a general way, but none of us really know. We had allowed the physicists to hold the field with their explanations, and after hearing their dissertations and seeing their diagrams, we had just for a moment felt that all was clear and definite, only to find, after mature consideration, that we had not made any real advance, and that our conception of chemical action was still as nebulous as ever. What was wanted, the speaker said, was a return to chemical reasoning. Taking as an example the chemical activity of enzymes, Dr. Armstrong spoke of the idiosyncrasies of such bodies, their sensitiveness to outer influences, their high "ideals" as regards selective action, their "personality." These special properties they derived from structure and a very large reactive surface. The extreme difficulty of investigating such sensitive complexes as the enzymes was pointed out, and Dr. Armstrong showed that we had come to some understanding of their methods of reaction by careful study of the mechanism of the hydrogenation of fats in presence of finely-divided nickel. The central fact here was that the curve expressing the rate of reaction did not indicate mass action, but was a straight line, showing that the speed of reaction was sustained until 80 per cent. or even more of the fat had been hydrogenated. This measurement was of the speed of the slowest reaction taking place. The volume of criticism which has been directed against these results was mentioned, and emphasis was laid on the need for the most scrupulous exclusion of catalytic poisons ; for, by the intentional introduction of these, a curve of the logarithmic type could be obtained. The orientation, and loose anchorage of the fat molecule on the nickel surface, where the hydrogen reacted and the hydrogenated molecule became detached, was diagrammatically represented. In conclusion, Dr. Armstrong spoke of the importance of such types of chemical reaction to the animal organism and the process of metabolism.

The influence of the various societies which exist for the promotion of pure and applied chemistry has hitherto been dissipated by separate action. To ensure intimate co-operation and to focus public attention on chemistry, it has been decided, in place of separate social functions, to hold this year a joint dinner of the following chemical societies: Society of Chemical Industry, Institute of Chemistry, Society of Dyers and Colourists, Glasgow University Alchemists' Club, the Andersonian Chemical Society, and the Ardear Chemical Club. Arrangements have been made to hold the dinner in the Grosvenor Restaurant, Glasgow, on February 23. Applications for tickets (12s. 6d. each) should reach the Hon. Secretary, Dr. J. A. Cranston, not later then February 16. It is expected that the Lord Provost and other prominent citizens will be present, so it is hoped that chemists and their friends will rally in strong numbers.

BIRMINGHAM AND MIDLAND SECTION

The meeting held on January 23 marked the first of two evenings devoted to the discussion of various aspects of the fuel problem. Mr. E. V. Evans, O.B.E., F.I.C., who presided, said the gas industry was old and well-established, attributes which were liable to check progress, and without competition from electricity the industry would not have progressed as it has done during recent years. Contributions from the Birmingham Gas Department were of considerable importance in this connexion, and tribute should be paid to the work of Dr. Davidson, Dr. E. W. Smith and Mr. Rhead. To-day the problems of the gas industry were more numerous than ever before, and whilst efforts had to be made to reduce the price of gas, the efficiency of the consumers' appliances required equal attention. Maximum revenue had also to be obtained from by-products, the net revenue from tar and ammonia representing 15 to 20 per cent. of the cost of coal delivered into store. Many promising fields of development in the distillation of coal and preparation of coke remained practically untouched. It was probable that gas undertakings would eventually manufacture not only gas but a smokeless solid fuel containing little ash, which would in time supersede the use of raw coal in the domestic grate and in industry. In this way the scope of the industry would be greatly increased, and the time was coming when the gas industry would take its place as an outstanding example of that application of science to industry for the furtherance of which this Society was founded.

Dr. C. H. Lander, Deputy Director of Fuel Research, then read a paper on "Some Aspects of the Fuel Problem." For the satisfactory elucidation of the main problem of the full utilisation of the fuel resources of Great Britain it is imperative that this be regarded from the widest point of view, and that a sense of proportion should not be lost by concentration on any particular side of the question, whether that of chemistry, engineering or physics. Broadly speaking, the purposes for which fuel may be used can be divided into two categories:—(*a*) The development of mechanical power at some particular spot, and (*b*) the introduction of heat into some substance, also at a particular spot. Hence the value of any form of fuel depends on its ease of transport as well as on its ease of application.

The programme of the Fuel Research Board as laid down on its inception in 1917 followed two broad lines:—(1) The survey and classification of coal seams. (2) Investigation into all the practical problems involved in the replacement of raw fuel as at present burned by fuel obtainable from coal by carbonisation and gasification processes.

Under the first heading comes the survey of the national coal resources inaugurated by the Board, the practical work in connexion with which is being carried out by local Committees, the first of which, in the Lancashire district, is now at work correlating information concerning the most important seams in that district, and supplementing this by experimental work on sampling and analysis on a small scale. The personnel of these Committees includes colliery owners, managers, consumers and representatives of outside scientific interests, as well as representatives of the Fuel Research Board and the Geological Survey. In connexion with the Survey, experimental work on the full-working scale on typical coals is being carried out at H.M. Fuel Research Station. An important scientific committee has also been appointed by the Board to recommend standard methods for the sampling and analysis of coal which, it is hoped, will render analyses by different investigators more readily comparable than heretofore. In addition to the experimental work which is being carried on, careful records and maps are kept by the Board in connexion with the various seams and coals dealt with.

The second line of inquiry has included the question of gas standards, into which the Fuel Research Board made a thorough investigation, at the instance of the Board of Trade, and recommended the thermal system of charging for gas as the only method by which it was possible both to protect the consumer and to afford to the gas industry a freedom which would render it possible to select in each case those methods which would procure the most economical results. This question of gas standards led to experimental work by the Board on steaming in vertical gas retorts as a means of converting the potential heat units in coal into good and saleable gas, and a report was published in 1921 on their investigations into typical coals treated in this manner. Further experimental work on steaming is also being carried out at the direct request of certain important gas companies, and a report on some experiments with water gas plant will be published shortly.

The latest report so far published by the Fuel Research Board dealt with the question of low-temperature carbonisation, a subject in which widespread interest has been displayed as a possible source of home supplies of fuel oil and in connexion with the demand for a smokeless fuel. During the course of the Board's experiments, which have been carried out on the full working scale, and are still continuing, close touch has been maintained with outside investigators. The Board is not without hope that the economic and social difficulties involved in the solution of this problem may be overcome in the near future. Other aspects of the main problem dealt with by the Fuel Research Board may be summarised as follows :—

(1) Power alcohol and the possibilities of its production within the British Empire for motor transport and for use in internal-combustion engines. (2) The winning and utilisation of peat, regarding which a report is now in the Press upon the result of the investigations of the Fuel Research Board into Canadian and Continental practice, as well as upon the experimental work carried out by the Board in Ireland and at H.M. Fuel Research Station. (3) The suitability of mixtures of fuels for internal-combustion engines. (4) Investigation into the fundamentals underlying domestic heating. (5) Utilisation of special fuels in boiler furnaces. (6) Pulverised fuel.

In a paper on "The Thermal Efficiencies of Manufacture of Different Grades of Gas," Dr. A. Parker, of the Department of Fuel and Coal-Gas Industries, Leeds University, said that the industrial position attained by this nation was due in a large measure to the possession of a good supply of coal. The nation could not afford to continue to use this asset except in the most economical manner ; and at the same time determined efforts must be made to eliminate the smoke nuisance and the damage it caused to health and property. There was ample room for the more economical use of coal. The ordinary domestic fire, which was largely responsible for the smoke nuisance, radiated only 25 units of heat into the room for every 100 units in the coal used. The consumer of electricity received less than 10 per cent. of the energy of the coal used at the central generating stations ; and of every 100 units of heat expended at the gas works of the country, only about 45 were delivered to the consumer. For some years there had been definite co-operation in scientific research between the gas industry and the University of Leeds. Dr. Parker described the work already carried out, and the improvements resulting from this co-operation, and mentioned that much of the work had been made possible by the generosity of the Birmingham Gas Committee in allowing the use of installations at its works.

MEETINGS OF OTHER SOCIETIES

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

The meeting held at Boston and Cambridge during the last few days of 1922 was full of interest to chemists as the topics discussed ranged from atoms and isotopes to photosynthesis.

Prof. T. W. Richards, of Harvard, told of his work on the change of bulk of atoms which he finds depends on compressibility and internal pressure. He showed diagrams of various atoms enlarged 200,000,000 diameters. Photographs of the tracks made by flying fragments of atoms were exhibited by Prof. W. D. Harkins, of Chicago. He took ten thousand photographs, many of which showed alpha particles colliding with atoms, similar to the pictures taken by Sir Ernest Rutherford in England. Professor Harkins hopes to prepare a kinematograph film showing the decomposition of the atoms by alpha particles.

By X-ray investigation Dr. G. L. Clark, of Harvard, has made an accurate map of the interior topography of various crystals. Thus cæsium tri-iodide forms a rectangular crystal which is somewhat similar in structure to the cubical crystal of the moniodide, but the two extra iodine atoms lie on the diagonals of the figure instead of at the corner or face positions.

By bombarding magnesium with high voltage electricity, Drs. C. Davisson and C. H. Kunsman have succeeded in finding out how the electrons are arranged in the magnesium atom.

Dr. R. S. Mullikan, of the University of Chicago, is attempting to separate the six isotopes of mercury by a novel form of distillation apparatus which carries off the atoms of mercury as rapidly as they evaporate from the surface of the boiling metal. The still is so efficient, that a ton of mercury may be evaporated in 24 hours in six glass flasks holding a pint each.

The changes undergone by certain carbohydrates were explained by Dr. C. O. Appleman, of the University of Maryland. He finds that the sugar in potatoes long stored in a cool cellar increases from about 0·3 to 5 per cent., but sweet corn (maize), which contains 5 per cent. of sugar, loses two-thirds of it shortly after it is pulled from the stalk.

The chemists of the Department of Agriculture have been engaged on the synthesis of thymol, a valuable antiseptic. Synthetic thymol, which is identical with the natural product, is manufactured from cymene, of which some 2,000,000 gallons are wasted annually in the United States and Canada.

An account was given of the new fumigating gas developed by the U.S. Public Health Service and the Chemical Warfare Service of the War Department. Cyanogen chloride or "tear" gas is mixed with hydrocyanic acid and used for fumigating ships, cars and houses to get rid of rats and other vermin. The new gas is easily detected in quantities too small to be dangerous to human beings and is harmless to foods, tobacco, fabrics, leather and metals.

Prof. Jacques Loeb, of the Rockefeller Institute for Medical Research, read a paper on the swelling of gelatin and other colloids. He considers that the electrical state of the aqueous solutions of these substances explains a large number of the anomalies which have been observed.

Dr. E. E. Slosson, of the Science Service, Washington, read a paper on the various sources of the world's power and how these are being gradually dissipated. Some day, he says, the world will have to stop drawing upon its carboniferous banks and live within its income. It will have to grow its fuel year by year as it grows its food.

Photosynthesis was discussed by Dr. Spoehr, of the Coastal Laboratory, Carmel, California, and Dr. S. E. Sheppard, of Rochester. Dr. Spoehr questions the commonly accepted theory that the formation of carbon compounds in plants proceeds by two simple steps, first the formation of formaldehyde from carbon dioxide and water, and second the combination of this to form sugar. British investigators claim that they have actually carried out these reactions in the laboratory, but Dr. Spoehr, in repeating their experiments, has failed to confirm their conclusions. Dr. Sheppard, in considering how the green leaf builds up sugars out of formaldehyde, admitted that no substance was as satisfactory as chlorophyll, but he pointed out the same reaction could be accomplished by the ultra-violet rays and cited experiments to show that when these rays act upon a solution of formaldehyde in water containing certain salts, such as sodium citrate and carbonate and copper sulphate, the formaldehyde is in part transformed into sugar. The work of Professors Baly and Heilbron was discussed.

INSTITUTE OF CHEMISTRY

The third general meeting of the Leeds Area Section was held in the Queen's Hotel, Leeds, on January 17. Mr. Mackey, who presided, read a paper on the "Professional Aspects of Sampling," in which he insisted that chemists should see their work through from start to finish. Sampling was often left to those who were not chemists and who were certainly not qualified to undertake the work, with the result that the analysis gave a misleading impression. If every chemist who was asked to evaluate a coal seam, or a deposit of iron ore, went to the mine and superintended the taking and preparing of the samples himself, it would add greatly to the value of his report. What might be termed "Departmentation" was to be deprecated and men working in the laboratory should be versatile and take an intelligent interest in what was going on around them.

Mr. Grinling, in his paper on "Work's Practice in Sampling," drew attention to the differences between samples taken for public analysts and consulting chemists, and those taken for work's control. The former, as a rule, represent the average of the whole consignment, whereas with the latter other factors have to be taken into consideration. If, for example, the whole consignment is not uniform in general condition and appearance, it will probably be necessary to take samples representing the different portions, each sample being separately analysed and reported upon. Sampling in a works presents several possibilities, all of which have their disadvantages. If, as sometimes happens, the sampling is done by individuals who know little about sampling and its importance, the results are nearly always unsatisfactory It is better for the chemist to take the samples himself, as it enables him to get first-hand information which may be invaluable to him when making his report, but taking into consideration the value of the chemist's time, this method is not economic. Probably the most satisfactory method is for the chemist to have a staff of trained samplers under his control. An efficient sampler must be a man of many parts; he must be a good clerk, very tactful, observant, clean in his methods and not afraid of hard work. Every works chemist should be able to take samples, but a sample, however carefully taken, is of little value unless it is properly labelled, and its full history attached to it. The keynote of successful sampling is common sense and a clear idea of what is wanted.

SOCIETY OF GLASS TECHNOLOGY

Prof. W. E. S. Turner presided at the meeting held in Sheffield on January 17. A very cordial welcome to the meeting was given to Mr. H. L. Dixon, of Pittsburgh, U.S.A., who was, said Prof. Turner, well known not only in America but also in England and on the Continent, and had built nearly all the glass furnaces in America. During the forenoon members had the privilege of visiting the works of Messrs. Thos. Firth and Sons, Ltd., Sheffield, where they saw various processes in the manufacture of stainless steel.

The first paper, presented by Dr. W. H. Hatfield, was entitled "'Stainless' Steel, with some Consideration of its Application to the Glass Industry." At the outset, Dr. Hatfield stated that he could not do more than suggest some directions in which "stainless" steel might be useful in the glass industry. The most important property of stainless steel was its resistance to corrosion and to oxidisation.

Resistance to ordinary corrosion was not of much interest to glass technologists, but resistance to oxidisation at high temperatures was of considerable importance, especially because the steel scaled at much higher temperatures than ordinary steels. Stainless steel had such different properties from ordinary steel that it must be studied as an entirely different material from many points of view. After demonstrating how nitric acid rapidly attacked ordinary steel but left stainless steel unaffected, Dr. Hatfield said that stainless steel could now be cast directly, and very malleable sheet steel could also be made. It could be drawn into tubes of such fineness that hypodermic needles were now largely made from the material. Turbine blades had been successfully turned, and in this case the steel was brought into contact with steam at high temperatures. He showed pieces of turbine blades that had been in use eighteen months and still retained their special properties, whereas under the same conditions ordinary nickel-steel blades had ceased to function properly. Practically all the turbine manufacturers had adopted stainless steel for the manufacture of blades.

Stainless steel was an alloy of iron with from 12 to 14 per cent. of chromium. The carbon content varied a little with the different types of stainless steel, but for general purposes might be considered to be about 0·30 per cent., which was very similar to that of ordinary structural steels. A stainless steel could now be made which was impervious to sodium sulphate, though some types of stainless steel were liable to be affected by continued contact with it. Micrographs were shown illustrating the structure of various special steels such as nichrome and tantiron. The former resisted oxidising influences and maintained its strength at high temperatures, and the latter was not ductile but relatively hard and brittle like cast iron. Stainless steels could be considered as alternatives for those now used in the glass industry from two standpoints, viz., resistance to scaling and strength at high temperatures. Stainless steel had a high tensile strength, equal to the best alloy steels, had a high fatigue range and might be hardened and tempered. There were many directions in which the material might be useful, the most notable being for parison and blow moulds. Many parts of feeder devices might be usefully produced in such material, as might also blowing irons, rolls, belt conveyers, lehr chain pins and other things, including knives for cutting viscous glass. The ends of blowpipes might very well be made of stainless steel. Brushes which had to be made of wire could well be made of stainless steel. Explaining recent developments in the use of this steel, Dr. Hatfield said that where a highly polished surface was needed, stainless steel was admirable for the purpose. Indeed, several firms were producing scientific mirrors from this material.

A discussion followed, in which there took part Prof. W. E. S. Turner, Major V. F. Gloag, and Messrs. J. H. Davidson, W. C. Snowdon, R. Hemingway, and Guy Simpson. Replying to the discussion, Dr. Hatfield said that the question of a good surface was answered by the manufacture of the mirrors he had referred to. Stainless steel would do very well in muffle lehrs, and it could be easily welded to stainless or ordinary steel, but a good deal depended on the skill of the smith employed. He thought that the moulds used in glass-making were too heavy. Stainless steel could withstand crushing and ordinary wear and tear as well as most materials. He could not give information as to comparative costs, but the cost of stainless steel approximated to that of cheap high-speed steel; it was a special steel, and not a cheap steel, but the cost was not prohibitive. The expense was always justified when used in those industries where its special properties gave it an advantage over other materials.

The second paper was entitled "Some Measurements of the Viscosity of Glasses near their Annealing Points and a critical Review of some recent Literature on the Annealing of Glass," by S. English, M.Sc. Mr. English showed that, contrary to the general opinion, strain in glass could not always be detected by examining the glass in polarised light, and that the most sensitive position was that in which the direction of the strain in the glass was at 45° to the plane of polarisation of the light. In discussing strain viewers, the lecturer dealt with the defects in design of a strain-viewer recently put on the market and showed that with a strain-viewer of this type it was very easy to obtain misleading indications of the presence of strain. Reviewing the statements made concerning the advantages accruing from the use of a selenite or quartz plate in connexion with the analysing nicol prism, it was shown that the claim made by one author that the selenite plate was more sensitive than plain crossed nicols was only true when a very poor source of light was used, and that a further claim made by another author to be able to distinguish between tension and compression stresses by the use of such a plate was entirely untrue. Details of the measurements of the mobility of various types of glasses from the annealing temperatures through a range of 150° C. were given, and it was shown that the rate of change of mobility of the glasses at their annealing points was approximately constant, most of them requiring a rise in temperature of 9° C. to cause a doubling of the mobility. In some cases this temperature interval rose to as much as 11° C. At temperatures of 100° or 150° C. above the annealing points the temperature interval required to double the mobility was generally rather wider than that required at the annealing points. Curves were shown indicating that the mobility of glasses is not a true logarithmic function of the temperature, and that a point of inflexion in the curves will probably be found at temperatures rather higher than those included in the present range. It was also suggested that the well-known working properties of lead glasses and other soft glasses were determined more by the rate of radiation of heat than by rate of change of viscosity with temperature.

BIRMINGHAM UNIVERSITY CHEMICAL SOCIETY

Professor G. T. Morgan delivered his presidential address to the Birmingham University Chemical Society on January 22. There was a very large attendance of students and industrial chemists numbering over 200.

After referring to the Empire's resources in the precious metals, gold and silver, and also in the light metals aluminium, magnesium and beryllium, which are of special interest in the production of light alloys, Prof. Morgan said that ultra-light alloys are now being produced by the Magnesium Co., Ltd., of Wolverhampton. The metals of the less common earths are utilised chiefly in the form of their compounds. Barium and strontium preparations are mainly derived from British sources, and the world's requirements for thoria and ceria employed in the incandescent mantle industry are largely supplied from the extensive Travancore deposits which will meet the demand for many years.

The favourable situation of the Empire in regard to the supply of tungsten minerals should place us in a premier position for manufacturing tungsten steel—one of the great triumphs of modern metallurgy—but before the war, Germany controlled two-thirds of this production, the importation of German tungsten into this country having an annual value of £300,000. This unfavourable position, which existed up to July, 1915, contributed to the shortage of shell which jeopardised the military operations in the late war. In the development of our mineral resources it is essential to take the long view. Systematic research is needed even on chemical elements which have not hitherto received industrial application. Zirconium provides an instance of a metal which has so far been examined chiefly by German and American chemists, the English contribution to this branch of mineral chemistry being very small. Quite recently two Danish chemists have announced the discovery of a new element from zirconium mineral. Cobalt is another example of a metal which merits increased attention, the annual production being only of the order of 400 tons. The chief deposits are in Ontario, and Canadian chemists are becoming prominent as investigators of this element. There is a world shortage of the valuable metals of the platinum group owing to the partial failure of the Russian supply. These metals have been detected in many parts of the British Empire. Tasmania has furnished osmium and iridium and the nickel-copper ores of Sudbury, Ontario, have yielded notable quantities of platinum and palladium. Cobalt has a promising future as an alloy metal, as it confers hardness and durability on aluminium ; until recently cobalt was only used in combination as a pigment colouring material. The possession of this varied assortment of mineral wealth carries with it the obligation to utilise this heritage to the best advantage to humanity. If the present possessors fail in this respect sooner or later the task will be undertaken by others.

The chief reason why the synthetic-colour industry has become a so-called "Key" industry is an educational one. A highly developed industry in coal-tar products leads with unfailing certainty to proficiency in other chemical arts. The main thesis which should be pressed on the attention of all our public men and leaders of industry is that of safeguarding our natural resources in *materia chemica.* There is only one strategic chemical front, and we can not fall behind in any particular branch of chemical trade without grave risks of losing ground in all the correlated industries.

In conclusion, Prof. Morgan said he thought he had said sufficient to show that there was sufficient work to be done by all the chemical students from the Birmingham and other English Universities. In spite of trade depression and the enormous output last summer of more or less trained chemical students under the Government scheme, the numbers of chemists unemployed or seeking positions are very small. Although our industry is under a cloud for various reasons, the outlook is not bad for the adequately trained chemist.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

A lecture on the nitrogen-fixation plant at Muscle Shoals, Alabama, U.S.A., was delivered at the meeting which took place on January 17, by Mr. John Frazer, Professor of Chemistry, and Dean of the Towne Scientific School of the University of Pennsylvania, who is now in France for the purpose of lecturing before various French Universities. The lecturer observed that the site was admirably chosen, and the enormous plant itself was erected with extreme rapidity, but at very heavy expense. At present the factory is lying idle, owing to the lack of interest shown by American farmers in the use of ammonium sulphate, a product which the plant was built to produce by the cyanamide process.

THE INSTITUTION OF CHEMICAL ENGINEERS

The first meeting of the Provisional Council was held on January 10, 1923, at 166, Piccadilly, London, W. 1. The solicitor reported that he had received from the Board of Trade the Certificate of Incorporation and the order of the Board of Trade giving authority for the Institution to commence work.

Sir Arthur Duckham, K.C.B., M.I.C.E., was elected the first President of the Institution, and Mr. K. B. Quinan and Dr. C. C. Carpenter were elected the first Vice-Presidents of the Institution. Prof. J. W. Hinchley, Wh. Sc., A.R.S.M., was elected Honorary Secretary, and Mr. F. H. Rogers, M.I.M.E., as Honorary Treasurer. The President announced that he would have great pleasure in presenting to the Institution its Seal.

It was decided to hold the first Annual Meeting of the Institution on March 14, 1923, in London.

A list of names was approved for election, and the Selection Committee was then elected as follows :—Messrs. J. Arthur Reavell, M.I.M.E. (Chairman), Prof. J. W. Hinchley, F. H. Rogers, M.I.M.E., E. W. Smith, D.Sc., Wm. Macnab. Mr. C. S. Garland, M.P., Mr. S. G. M. Ure and the Hon. Secretary were elected to discuss the question of taking part in the British Empire Exhibition in 1924 with Mr. Woolcock. Mr. W. J. U. Woolcock was unanimously elected an honorary member of the Institution. The next meeting of the Provisional Council will be held on February 21, 1923, at the offices of the Institution.

CORRESPONDENCE

PROFESSOR ARMSTRONG AND THE SMOKE ABATEMENT COMMITTEE

SIR,—I have read with some interest and a little amusement the strictures which Prof. Armstrong has been pleased to pass on the Committee appointed by the Ministry of Health to inquire into the abatement of smoke and noxious vapours. His assertions that " nearly all the evidence was directed to proof of nuisance and in some cases to the difficulty, if not impossibility of avoiding it," " that very little constructive evidence was taken and this related to the use of gas or central-heating appliances," that " smokeless, easily-combustible solid fuel was considered only on two occasions " and that "no scientific evidence was given on the subject," are simply misstatements of fact.

In the first place it should be pointed out that the Committee visited a number of industrial centres in order to inquire on the spot into the cause of the smoke or other nuisance from noxious fumes. At these places very many persons, desiring to lay complaints before the Committee, were given an opportunity of being heard and they, of course, swelled the number of persons whose evidence appears in the report. Prof. Armstrong omits to mention this and does not trouble to discriminate among the 130 witnesses between those who were invited to give evidence and those who were not. Out of curiosity I have been through the list of witnesses, leaving out the uninvited who merely wished to lodge complaints, and have divided them into what might be termed constructive witnesses and those who gave evidence in regard to damage by noxious fumes and smoke. I think that even Prof. Armstrong must admit that something more definite than a mere opinion in regard to the extent of damage to health and property is demanded before any serious legislation could be justified.

The constructive witnesses, who numbered upwards of fifty, included seven architects, five heating engineers and experts, five gas experts, two electrical engineers, seven smoke and sanitary inspectors, six manufacturers of iron, steel, copper, spelter and tinplate, two producers of low-temperature coke as well as Sir George Beilby, who supplied scientific evidence on the subject, three manufacturers of pottery by coal-fired and producer-gas furnaces, a chemical expert in pottery manufacture, an iron and steel works chemist, the late and present chief alkali inspectors, a professor of metallurgy, a few manufacturing chemists and one or two witnesses called to clear up the legal aspects of the question. None of this evidence was given as a proof of nuisance and as regards low-temperature coke we collected all the information that was available at the time, whilst some of us took the opportunity of seeing the plant and of testing Mr. MacLauren's and the Barnsley products. On the side of evidence of nuisance or damage we heard seven medical men, two agriculturists, Sir Frank Baines of H.M. Office of Works, Miss Fitzgerald, of Manchester, who gave information in regard to the cost of washing and a number of witnesses, as previously stated, who wished to lodge complaints of smoke and noxious fumes. Prof. Armstrong states that the Committee included one chemist who had been engaged in measuring fog and its effects. There were, as a matter of fact, two chemists, Mr. Curphey, the late chief alkali inspector, and myself. It is, however, impossible to discover which of us has the distinction of being the chemist designated by Prof. Armstrong as neither of us, so far as I know, has been engaged in the manner he described.

Prof. Armstrong is a distinguished man of science and no one would for a moment doubt his sincerity in denouncing an abuse where it exists, but as a man of science he should realise the value of facts. He has taken no pains to do this and has, consequently, passed an entirely false judgment on the work of the Committee. He repeats the word " constructive" five times in one column; but I have failed to discover in his remarks one constructive idea unless it is the use of "dust-fuel" to which he refers in passing. Is he using it or doing anything to promote its use? He seems to attach great importance, as we all do, to the production and use of low-temperature coke. At the time when the report was compiled the Barnsley works was supplying it at 60s. a ton at the works when coal was costing about 50s. delivered. It has now come down to 35s. at the works; but is still as dear as or dearer than coal. One cannot force people to buy low-temperature coke unless they find some advantage in price, and, if so, what constructive action does Prof. Armstrong propose to take?

I would say, in conclusion, that had Prof. Armstrong, instead of girding at a Committee for its supposed shortcomings, used the columns of your journal for introducing really practical suggestions or what he would call "constructive" ideas, how much more valuable would his contribution to the subject have been! Fault-finding is so very easy.

J. B. Cohen

CATALYSIS

(With apologies to the late Sir W. S. Gilbert)

Scene.—The surface of a piece of charcoal

[Enter a Chlorine molecule. She sits down dispiritedly on two adjacent carbon atoms and sings:—]

Here am I a Chlorine molecule so free,
Hey but I'm doleful, willow willow waly,
Nothing that I care for will combine with me,
Hey willow waly O.
Nothing that I care for will combine, and therefore
Hey willow waly O!

[Enter a molecule of CO—very smart, morning coat, silk hat, etc.—sits down on two adjacent carbon atoms beside her.]

CO:
Prithee, nascent Chlorine, will you marry me?
Hey but I'm hopeful, willow willow waly.
I may say at once I have lots of energy,
Hey willow waly O.
Energy, I use it, other compounds lose it,
Hey willow waly O.
Chlorine:
Radiant Sir, altho' I'm wishful to combine,
Hey, but I'm joyful, willow willow waly,
Never dared I hope for cavalier so fine,
Hey willow waly O.
I will follow ever, decomposing never,
Both:
Hey willow waly O.
[They go off arm in arm.]
[Curtain]

R. T. M. H.

THE "ORGANIC" CHEMIST

Sir,—Excuse me laughing, but I can't help it. If Charles Dickens were alive he would make nearly as much fun of chemists as of lawyers, touching their quibbles and verbose pleadings. I am not a chemist—at least, I have given up thinking that I am. Fifty years ago I got the idea into my head that I was a chemist, but in recent years phase rules, ions, electrons, emanations, isotopes, higher mathematics and such like terrors have knocked the conceit out of me and forced me to escape the muddling throng and take refuge in the strangers' gallery to watch the show in comfort. It is at times entertaining. Nearly a hundred years ago Wöhler knocked to bits the barrier that separated "organic" chemistry from ordinary chemistry. Ever since chemists have been trying to readjust the barrier, sometimes a bit nearer and sometimes a bit further with more or less "no man's land," but only to find that it is a phantom anyone can walk through if he wants. But if the term "organic chemistry" is silly, the height of absurdity is reached in the word "organic chemist." Names such as Metallic Chemist, Watery, Beery, Gassy, Oily, Soapy Chemist or Irony, Steely and Brazen Chemist would be just as sensible.

"Wheerfur—Theer! I la'af!"

—I am, Sir, etc., Joseph Barnes

THE HUMAN ELEMENT IN THE CHEMICAL INDUSTRY

Sir,—Those of us whose main concern is the human side of the Chemical Industry are able to appreciate at its full worth Viscount Leverhulme's recent letter to you. One fears that in the Chemical Industry, as in most others, the human problem was more or less ignored in pre-war days. Seldom was the task of dealing with the employees entrusted to one individual as his especial responsibility. Boards of directors, generally speaking, were not accustomed to concern themselves with questions affecting their workmen unless and until serious trouble threatened. In point of fact, the war was responsible for awakening employers to a realisation of the existence of a "Labour Problem." Previously, one never heard that expression. During the war, however, the atmosphere of comradeship induced by the existence of a common peril, caused employers to realise at long last that those who before the war had been merely "hands" were in reality human entities with legitimate needs and aspirations which demanded fulfilment.

With this discovery came the belated recognition of the fact that the management of workmen is a science, and consequently a function that can only be efficiently performed by persons with the requisite qualifications. It was a great step forward when firms began to appoint "labour managers" who were presumed to be men with inborn tact and a thorough understanding of human psychology. The concentration into the hands of a capable labour manager of all questions relating to labour was found by countless firms throughout the country to result in infinitely smoother relationships with the men and a consequent higher efficiency of production.

(In passing, I would like to draw attention to one direction in which I found American employers more far-sighted than British employers. American employers have recognised that even with a generous-minded directorate and a considerate management, the wheels of industrial relationships frequently become clogged owing to the foremen not being educated in the science of "man-management." As a result, many American firms give their foremen a course of training which helps them very considerably in meeting the thousand-and-one little difficulties with which they are continually faced. British employers would do well to emulate their American cousins in this respect, and to judge a foreman more by his capacity for dealing wisely with his men than by his mechanical efficiency or driving capacity.)

In addition, however, to teaching us the value of specialised labour management in the factories, the war taught us the value of a corporate sense in an industry. There was no corporate sense in the Chemical Industry so far as its treatment of labour questions was concerned. Each chemical firm, whether it employed scores or thousands of men, was a separate unit depending solely on its own judgment for guidance in dealing with its workmen. The largely-increased number of labour questions caused by war conditions led to a number of chemical manufacturers meeting together informally to exchange notes and to seek or give advice one to the other on some knotty labour point. The success of this venture prompted the formation of the Chemical Employers' Federation in June, 1917. The first two points laid down were:

1. (1) That the Federation would deal with nothing but labour questions, and
2. (2) That its members were in honour bound to send to its deliberations the men (directors if possible) who were responsible for the labour matters of their respective firms.

The result of adopting these two basic lines of policy has been that those chemical firms who are members of the Federation have the advantage of the collective assistance and advice of the men who personally handle their own labour problems daily, and who, by interchange of opinions, etc., round the Federation table, are continually becoming more expert in the science.

It should be noted that from its inception the Chemical Employers' Federation has consistently endeavoured to satisfy as far as possible those legitimate needs and aspirations of the workmen, to which reference has already been made. It has failed to satisfy them completely, and must necessarily fail, of course, because in a progressive civilisation needs and aspirations grow faster than does the power to satisfy them. The main thing for enlightened employers is to ensure a continuing effort to satisfy; stifled aspirations are the most fertile soil for the seed of unrest.

Many employers fall into the error of thinking that workmen are actuated first and last by financial considerations; chemical manufacturers have not done so. They have recognised through the activities of the Chemical Employers' Federation that "man does not live by bread alone," and that the most essential thing for a working man is to be assured of the dignity of his labour, and to feel that he is a factor, however humble, in the industry in which he is employed. The Chemical Employers' Federation has tried to give the men this assurance by creating wherever possible joint bodies representative both of employers and workpeople, in order that the common interests of both may be fully and freely discussed in a spirit of sincerity that shall convince the workman that he is regarded as a helper and not a chattel.

Joint bodies of this kind will never satisfy the workmen, however, if they degenerate into occasions for the mere interchange of pleasant compliments. They must be constructive, and in the chemical industry they have been so. One result has been the abolition of the old 12-hour shift system of working; another, the supersession of the plan whereby shiftmen worked every day, weekday, Sunday and Bank Holiday, without any additional remuneration, by the payment of overtime for Sunday and holiday work. A third result has been a very marked improvement in time-keeping, induced by the grant of a week's holiday annually with full pay to those who observe a certain standard of time-keeping. The first year that promise was made 45 per cent. only of the men earned the holiday; the second year the percentage jumped to 70, and is still improving. One firm employing over 5,000 men affords a wonderful example of the advantages of the annual holiday. Those men who do not lose more than two days in the year without reasonable excuse ("lates" being counted) are given a week's holiday and two weeks' pay. Last year 99 per cent. earned their holiday, and this remarkable figure is but decimal points higher than those of the preceding years.

I think we are right in claiming that the Chemical Employers' Federation was the first body of its kind to see the advantages both to workmen and employers of the annual holiday, and to put the scheme into force for an entire industry.

A criticism has been made that the Federation was apparently an organisation "for giving money away," the implication being, of course, that improper and costly concessions were made to the workmen. It is true that chemical workers' wages reached, and even now are at, a higher percentage above pre-war than those of almost any other corresponding class of labour, but the Chemical Employers' Federation has consistently considered the welfare of the industry in making its wage proposals. In fact, the Chemical Employers' Federation was the first body to recognise that wage advances must stop and that the then level of wages must be reduced. For some months we were as "a voice crying in the wilderness," but ultimately other industries admitted the correctness of our attitude and followed suit. Our policy has been to pay as high wages as are consistent with the national interests and with the future prosperity of our industry. In pursuance of that policy, our rates have been unchanged since April 1, 1922, and are now stabilised until April 1, 1923.

I have endeavoured to show that Viscount Leverhulme's formula for dealing with human nature is in active operation in the heavy-chemical industry at least, and it is our great regret that the organisations which exist in other sections of the chemical trade cannot see their way to join forces with us, so that our industry as a whole might present to the world the example in "labour management" that it does in scientific attainment and efficiency.—

I am, Sir, etc., R. Lloyd Roberts,
Secretary, Chemical Employers' Federation.

Winnington, Northwich.
January 18, 1923.

THE JOURNAL

Sir,—I read with interest the letter containing suggestions from three technical chemists, and agree with them, with the exception of one point, namely, the necessity of a journal embracing pure and applied chemistry.

I would suggest that the *Journal* of the Society of Chemical Industry remain a journal of applied chemistry.

The duplication of papers and abstracts is bound to take place when every scientific society is working independently, trying to cover every branch of chemistry.

What is required is a system of exchange whereby our members can obtain papers and abstracts from societies dealing with the various branches of chemistry. As it is now, if a chemist is a member of three or four societies, he receives similar abstracts from each society, and as a consequence retains his interest in one and loses it in the others.

The cost of subscriptions to many societies is very heavy and must be considered.—I am, Sri, etc., R. C.

Erratum.—The name of the author of the obituary of Dr. Lunge, published in the issue of January 26, should read T. W. Stuart, not T. W. Stewart.

PERSONALIA

Dr. H. S. Allen has taken up his duties as Professor of Natural Philosophy in the University of St. Andrews.

Mr. A. Hutchinson has been appointed to the University Lectureship in Crystallography established at Cambridge in connexion with the special Board of Physics.

The Royal Scottish Society of Arts has awarded a Keith Prize to Dr. D. Turner and Mr. D. M. R. Crombie for their paper on "An Investigation of the Ionised Atmosphere around Flames by means of an Electrified Pith Ball."

Messrs. Clayton, Son and Co., Ltd., of Leeds, have given 500 guineas and the Tottenham District Light, Heat, and Power Co. 250 guineas towards the cost of the experimental coal-gas plant, for the investigation of problems in the carbonisation and gasification of coal, which is being erected by Mr. Henry Woodall at Leeds University in memory of Sir Corbett Woodall.

* * *

The death is announced of Prof. J. B. Haycraft, well-known for his investigations into physiological problems such as the chemistry of the blood, the senses of taste and smell, and animal mechanics.

With regret we announce the death of Mr. F. E. Weston, B.Sc., Head of the Chemistry Department of the Polytechnic, Regent Street, and a member of this Society. In addition to his work as a teacher, Mr. Weston was the author of several treatises, of which "The Detection of Carbon Compounds" is perhaps the best known, and of late he had devoted much attention to the use of clay in soap-making.

NEWS AND NOTES

BRITISH INDIA

Forecast of the Indigo Crop, 1922–23

The final general memorandum on the indigo crop of 1922–23 estimates the total area at 296,800 acres, or 7 per cent. less than the final estimate last year. The total yield of dye is estimated at 2730 tons, which represents a decrease of 11 per cent. on the final revised estimate of last year.—(*Ind. Tr. J.*, *Jan.* 4, 1923.)

Forecast of the Sesamum Crop

The final forecast of the sesamum crop is as follows:—Final forecast for 1922–23 (including Burma): area, 4,847,000 acres; yield, 428,000 tons. Final forecast for 1921–22 (excluding Burma): area, 4,450,000 acres; yield, 450,000 tons.—(*Ind. Tr. J.*, *Jan.* 4, 1923.)

UNITED STATES

Mesothorium

Dr. R. B. Moore, chief chemist of the U.S. Bureau of Mines, in a short preface to a pamphlet on mesothorium, published by the U.S. Bureau of Mines, states that mesothorium is now used as a substitute for radium, not only for luminous paint, but also for medical purposes, and that it is now being recovered—as a by-product in the extraction of thorium—by two companies in the United States.

Dr. Schlundt gives an account of the radio-active changes of the elements of the thorium series and a table of the radioactive constants. Accounts are also given of the determination of the ratio of mesothorium to thorium, of the γ-ray activity of thorium D, of the extraction of mesothorium from monazite sand and its concentration by fractional crystallisation of mesothorium bromide, and of the decay of radiothorium and mesothorium preparations. A bibliography is appended to the pamphlet.

GENERAL

The Existence of a Hitherto Unrecognised Factor Essential for Reproduction

In a recent number of *Science* (*December* 8, 1922), two American investigators, H. M. Evans and K. S. Bishop, working at the University of California, have given a preliminary account of their researches on the reproduction of animals fed on diets composed of mixtures of "purified" foodstuffs. They have observed that rats fed on a diet apparently adequate as regards protein, fat, carbohydrate, salts, and at least two of the vitamins, A and B, are usually sterile in the first generation, but certainly fail to reproduce in the second. The sterility observed in such cases appears to be of a highly characteristic type. Natural foodstuffs contain a substance, X, which prevents the onset of sterility or cures it when it has been induced by the defective diet. As far as the authors can ascertain, the newly recognised dietary factor can be differentiated from any of the accepted vitamins, A, B, or C.

The results announced by these American workers are of great interest, but it may be wise to await fuller details of their experiments before accepting their main conclusion. It must be remembered that there are many difficulties in attempting an interpretation of observations such as Evans and Bishop have made. Thus, for example, the conclusion that the vitamin A is not the factor concerned is based on the results of experiments in which the effects of butter and cod-liver oil were compared, without, perhaps, sufficient attention being paid to the very wide variations in the amount of vitamin A present in these two oils. Doubtless the authors have considered such possibilities, and when their full results are published more detailed evidence in support of their views will be presented. Anyone who has carried out controlled experiments on the feeding of animals will probably agree that the first function of the body to be suppressed or damaged when the diet is deficient, either quantitatively or qualitatively, is that of reproduction, and the writer of this note has had many experiences, both with small animals such as rats and mice and also with farm animals such as pigs, which demonstrate that sterility may be induced by several types of dietary deficiency. Whether or not the main conclusions of the investigators at the University of California are correct, their experiments certainly provide additional evidence of the great importance of fresh foodstuffs, and constitute another warning against the modern tendency in food production whether for human use or for the rearing of farm stock.

The Hardness of Vitreous Silica

In a letter to *Nature* of January 6, Mr. Cosmo Johns and Prof. C. H. Desch describe experiments on the hardness of vitreous silica. The commercial silica glass has been described as softer than quartz, and this has been a difficulty in the way of Beilby's theory of hardening, according to which the vitreous modification should be harder than the same substance in the crystalline condition. The sample of silica used was melted on the top of the slag in an open-hearth steel furnace when the temperature was exceptionally high. It was completely isotropic, and the hardness, as found by scratching tests by the sclerometer and by the scleroscope, was distinctly greater than that of crystals of quartz.

Petroleum Production in Russia.

The following figures have been published concerning the production of petroleum in Russia during the first half of 1922 and the corresponding period of 1921 :—

District	Long tons raised to July 1, 1922	Long tons raised to July 1, 1921
Baku	1,492	1,281
Grosny	726	658
Emba	64	12
Total	2,282	1,951

These figures indicate an increase of 331 tons, or 17 per cent. over last year's production. On the average the intended programme was exceeded. The number of bore-holes has increased. During July 26,215 storage tanks were filled, or 3,950 more than during June.

The Use of Fertilisers on Forest Land

The old idea that the yield of wood could not be increased by applying fertilisers to forest land is, as the result of recent research, shown to be erroneous, treatment of the land with fertilisers containing nitrogen, potash, phosphoric acid and lime having resulted in many cases in a considerable increase in the growth of the trees. A test extending over 14 years has been carried out at Owing, Sigmaringen, on the slopes of the Jura Mountains, where a stretch of land that contained only a few pine trees and juniper bushes, and had been used for some time for pasturage, was divided into two parts, one of which was treated with nitrogenous fertiliser and sown with Swedish clover. Both parts were then planted with firs and divided into sections some of which were completely, and others partly, fertilised, whilst others were left untreated. Between 1906 and 1920 the average increase in height of the trees in the sections treated with Thomas meal and kainite was 523 cm., in those treated with Thomas meal alone 513 cm., and in the untreated sections only 408 cm. Ground burnt lime by itself effected very little improvement in the growth. Trees in the sections planted with clover showed a very considerable increase in growth, especially in the first year, but the tests on the whole showed that equally good results may be obtained by the use of mixed fertilisers without a previous crop of leguminous plants.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for January* 25)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Tiles	110
Canada	Tinplate, black sheets	82
”	Plumbago, dextrin crucibles	83
”	Steel, brass and nickel-silver wire	*
Chile	Rubber goods, leather, lubricating and lighting oils, grease (tender for)	7357/F.L./G.C.2
Egypt	Hides, pigskins (tender for)	†
Italy	Paper	91
Kenya	Red paint	10377/E.D./E.C.2
Morocco	Soap, candles	9661/F.E./C.C.
Netherlands	Formaldehyde, caustic soda, Epsom salts, sodium sulphate, ferrous sulphate, soda crystals, tartaric acid, sodium bisulphate and bicarbonate, sodium sulphite, copper sulphate, ammonium chloride, glacial acetic acid (98-100%), earthenware	96
”	Caustic soda	97
”	Tiles	98
Portugal	Copper sulphate, fertilisers	7226/F.L./E.C.2
South Africa	Brass and copper sheet	10387/E.D./E.C.

* Canadian Government Trade Commissioner, 73, Basinghall Street, London, E.C.2.

TARIFF CUSTOMS EXCISE

Argentina.—Importation of opium, heroin, cocaine and preparations thereof is subject to licence and permitted solely through Buenos Aires.

Australia.—A "dumping" duty has been applied to portland cement of United Kingdom origin, the duty representing the difference between the fair market value of the goods at the time of shipment and the export price.

British India.—The complete text of the revised tariff valuations is given in the issue for January 25. Among the classes of goods affected are fuel, gums, resins, lacs, ores, oils, wax, fertilisers, chemicals, drugs, medicines, dyes, colours, tanning materials, glassware, earthenware, hides and skins, iron, steel and various metals, paper pulp, paper, cement, china clay, pitch, and soap.

Denmark.—The regulations restricting the importation of footwear in the manufacture of which artificial leather or pasteboard has been used have been continued until the end of 1924.

Italy.—The statistical tax on imports has been increased from 20 to 25 centesimi per unit.

Poland.—The conditions under which import permits are granted are set out in the issue for January 25.

Spain.—A temporary commercial agreement has been made with Germany.

Uruguay.—Modifications have been made in the tariff valuation on perfumery and toilet articles.

REPORTS

REPORT ON THE ECONOMIC AND FINANCIAL SITUATION OF AUSTRALIA, REVISED TO OCTOBER 1922. *By* S. W. B. MCGREGOR, *H.M. Senior Trade Commissioner in Australia. Pp.* 94. *Department of Overseas Trade. London: H.M. Stationery Office*, 1922. *Price* 2*s.* 6*d.*

The state of depression in Australian commerce and industry recorded in the last Report (*see* J., 1921, 437 R) still obtains, largely owing to the difficulty of wages adjustment, which, however, must come before conditions return to normal. Although at present Australia is the United Kingdom's second best customer, British traders will have to employ every means in their power to retain their present share in the Australian market, in face of competition from the United States, and possibly from other countries. It is pointed out that the Bureau of Commerce and Industry numbers among its aims the encouragement of British manufacturers to establish branch factories in Australia. The Institute of Science and Industry has made further progress, and a new scheme provides for the formation of Bureaux of Agriculture, Industries, and of Information.

The total production of industries during the year 1920-21 was valued at £402,208,000, made up as follows:—Agriculture, 28%; pastoral, 23%; dairy, poultry, etc., 13%; forestry and fisheries, 3%; mining, 6%; manufacturing, 27%. The production of metals and minerals during 1921 has previously been analysed in these columns (*cf.* J., 1922, 131 R). The closing down of the Newcastle works of the Broken Hill Proprietary Co., Ltd., was an important incident in Australian iron and steel manufacture; this was attributed to the high cost of coal and wages, and the shortness of working hours. In 1921 the output of pig iron amounted to 352,365 tons, an increase of 8365 tons over 1920. Paints, varnishes and cement are now made locally in sufficient quantity to supply the home market, as are also bottles, though other glass-ware is imported. The Government offer of a premium of £50,000 has given impetus to oil-prospecting, but so far no oil has been found in the Commonwealth.

External trade for the year ending June 30, 1921, showed an adverse balance, imports amounting to £163,801,826, and exports to £132,159,912. The competitive imports amounted to £126,044,552, of which the United Kingdom supplied 61 per cent., U.S.A. 20 per cent., and Japan 4 per cent. The imports of manufactured metal goods were valued at £29,170,930 (the U.K. supplying 62 per cent. of this); of machinery, £9,873,285 (U.K. 48 per cent.); earthenware, cement, china, and glass, £3,158,152 (U.K. 39 per cent.); ammunition and explosives, £1,164,208 (U.K. 64 per cent.); chemicals, £4,637,410 (U.K. 52 per cent); paints and varnishes, £626,920 (U.K. 63 per cent.); oils, fats, and waxes, £493,396 (U.K. 41 peh cent.). The chief chemicals imported were:—Tartaric acid, £294,577; cream of tartar, 1356 tons; synthetic dyes, £412,841; proprietary medicines, £260,506; drugs, etc., £338,856; perfumery, £56,909. Of the exports the United Kingdom took £67,519,740, or 51 per cent. of the total; other British countries £25,916,368 (20%); the United States £9,965,575 (8%); Japan £3,117,572 (2%). In 1921-22 imports amounted to £101,063,661, and exports to £127,949,445.

Report on the Commercial, Industrial, and Economic Situation of China in July, 1922. *By* H. H. Fox, *Commercial Counsellor, and* A. H. George, *late Acting Commercial Secretary, H.M. Legation, Peking. Pp.* 64. *Department of Overseas Trade. London: H.M. Stationery Office*, 1922. *Price* 1*s*. 9*d*.

Although the commercial and industrial development of China has again been retarded by civil war, and in a lesser degree by floods and famine, yet industrial enterprise is progressing gradually (*cf.* J., 1921, 454 R), especially in the ports, and it is felt that the set-back to home industries which were established when foreign supplies were difficult to obtain, is merely incidental. The problem is to initiate, not to revive, an industrial system, and the Chinese frequently fail to appreciate the value of co-operation between foreign and Chinese capital and interests. The sugar industry has been declining for some time; the present production is estimated at 450,000 tons, and imports at 350,000 t. Sugar-beet planting has not been successful, but experimental cultivation is being continued. The vegetable-oil industry is important but badly equipped, though it caters for a large home consumption as well as export. Estimates of the annual output of coal varies between 10 and 18 million tons; the output of the Kailan Mining Administration, an Anglo-Chinese concern, is over 4 million tons per annum, and could be increased. The present production of iron ore is 1,500,000 t., of which about two-thirds is smelted in the country. Various other ores are produced, but the small demand has caused many mines, even some of old standing, to close down. Exports of lead and zinc ores increased, however, in 1921. With ample supplies of limestone and other materials available, cement manufacture is becoming one of the leading industries of the country, and one factory alone hopes to bring its annual output to 200,000 t.

Foreign trade in 1921 amounted to £297,959,671 (taking the Haekwan tael at its average value of 3s. 11$\frac{7}{16}$d.), of which imports made up £179,110,978 and exports £118,848,693. The general fall in world prices during the period must be considered when comparing the figures for the two years.

Of the total imports the United Kingdom supplied 16 per cent., Hong Kong 25 per cent., other British countries 6 per cent., Japan and Korea 23 per cent., and the United States 19 per cent. Among the chief items were:—Iron and steel, 155,644 t.; copper ingots and slabs, 28,415 t.; tin, block, 4493 t.; tinplate, 23,943 t.; cement, 150,829 t.; coal, 1,361,781 t.; sugar, 473,876 t. Of the following items the value only is stated:—Metals and minerals other than above, £2,220,695; dyes, colours, and paints, £5,788,073; matches and materials, £728,628; leather, etc., £1,684,700; glass, £728,354; soap and materials, £414,618; medicines, £139,476. Germany has restored her pre-war organisation for selling dyestuffs in China, helped by the depreciated mark. (For some details of the indigo market in China *see* J., 1922, 459 R.)

Of the exports, Hong Kong took 25 per cent., the United Kingdom 5 per cent., other British countries 5 per cent., the United States 15 per cent., Japan and Korea 31 per cent. Among the chief items were:—Pig iron, 157,625 t.; ores, iron and others, 55,495 t.; tin, in slabs, 6133 t.; antimony regulus, 12,466 t.; coal, 1,886,398 t.; oils, vegetable and essential, 126,883 t.; tallow, 8477 t.

REVIEWS

Synthetic Colouring Matters. Colours Derived from Pyridine, Quinoline, Acridine and Xanthene. *By* Prof. J. T. Hewitt, F.R.S. *Pp. xi*+405. *London: Longmans Green and Co.*, 1922. *Price* 14*s*. 6*d*. *net*.

This work is trebly welcome, first because it is the initial volume of the half-dozen monographs on colouring matters to be issued in Sir Edward Thorpe's series of "Monographs on Industrial Chemistry," secondly because it deals with a number of small groups of dyes which are, for the most part, inadequately treated in existing text-books, and lastly, and perhaps most important of all, because the book emanates from one who is recognised as an expert in the subject and whose researches have done much to settle the problems connected with these classes of dyes.

Originally, as Prof. Hewitt tells us, it was his intention to write a single work on dyes of the Acridine, Xanthene, Azine and Oxazine groups, but later the large amount of material available made it desirable to write two books dealing with the Azines and Oxazines on the one hand and with the Acridine and Xanthene dyes on the other. In view, however, of the importance which has been attached of late years to the sensitising dyes of the Quinoline series, dyes derived from Pyridine and Quinoline have been included in the present volume. Accordingly we have a separate chapter dealing with the constitution and preparation of the Cyanines and Isocyanines and related compounds which summarises in an admirable way the important researches carried out during the war which enabled Prof. Pope and Dr. Mills and their co-workers to prepare at Cambridge the dyes used in sensitising the photographic plates used by the Allied air forces in the struggle, thus contributing in no small measure to the final victory. It is a pity that the book was published just too soon to include a reference to the work of Mills and Braunholz upon the Cyanines derived from oxythionaphthene which possess certain valuable properties, but this group of colouring matters is now being so intensively investigated that no book can hope to keep level with it, and we are grateful to Prof. Hewitt for bringing the subject right up to 1922. (In passing it may be noted that the missing reference to Williams on p. 55 should be to British Patent 1090 of 1859.)

The only adverse criticisms that might be made are—apart from the few inevitable misprints—that in the desire to document the book fully the author has, perhaps, made needlessly long extracts from German patent specifications which, as he himself says, do not always contain the whole truth and nothing but the truth. It would probably have been better in most cases where several examples are quoted for the same type of reaction to have given the results in tabular form, omitting all references to actual quantities and times, for which in any case the original patents would have to be consulted; for these reasons certain parts of the book are of unnecessary length and could quite well be abbreviated.

Lastly, as a certain amount of information has been forthcoming of late years on actual manufacturing processes one would have appreciated, where possible, a little fuller treatment of the actual works, processes and diagrams of plant used.

But it is always easier to criticise than to do a thing oneself, and those who have had experience of dealing with the publication of works on this branch of chemistry will recognise the vast amount of care and labour which Prof. Hewitt must have expended on the production of the present excellent volume and their gratitude and thanks are due to the distinguished author for contributing a really valuable addition to chemical literature.

FREDERICK A. MASON

BLEACHING POWDER AND ITS ACTION IN BLEACHING. *By* R. L. TAYLOR. *Pp.* 78. *Manchester and London: John Heywood, Ltd.*, 1922. *Price* 4*s.* 6*d. net.*

This book is a collection of papers which the author published in the *Journal* of the Chemical Society and in the *Journal* of the Society of Dyers and Colourists during the period 1910–1922. One is disappointed to find that the author's earlier papers on hypoiodous acid are not included, for this work was referred to by an Austrian chemist as "Die schoenste Arbeit von R. L. Taylor," and there is no doubt that it will be the means of preserving Taylor's name in the memory of chemists.

It is difficult to justify the re-issue of papers in book form, although it is sometimes done for the purpose of reviewing a period of development in some branches of chemistry; but it is probably better to give a summary of the papers, pointing out how criticisms have been met and emphasising the final conclusions drawn from the series of papers. The latest opinions are the only ones which matter, and little is to be gained by reiterating views since abandoned.

The work on the action of air and of carbon dioxide on bleaching-powder solution has been carefully carried out and is a record of well-conceived experiments, but in giving an opinion on the work on bleaching, the reviewer is in an awkward position, because he has engaged in a controversy with Taylor on the subject. Moreover, a large portion of the book deals with this controversy or one side of it. It is, however, interesting to quote the opinions of a third party, namely, S. R. Trotman (*cf.* J., 1922, 222 T), on points in the controversy: "I am of the opinion that for weak solutions of bleaching-powder, such as would be used in bleaching, Higgins's view is correct"; and before the Nottingham section of this Society on November 22, 1922: "Bleaching . . . . is probably due to the gradual formation of hypochlorous acid." As previously mentioned, Taylor's book would be improved were it made a fuller record of all his researches, which were carried out during a very busy and effective life devoted to the teaching of science in Manchester.

S. H. HIGGINS

TABLES ANNUELLES DE CONSTANTES ET DONNÉES NUMERIQUES DE CHIMIE, DE PHYSIQUE, ET DE TECHNOLOGIE. *Published under the auspices of the International Union of Pure and Applied Chemistry. Vol. IV.*, 1913–1916. *Part I., pp.* 626; *Part II., pp.* 627–1377. *Paris: Gauthier-Villars et Cie.; London: Cambridge University Press; Chicago: University of Chicago Press.* 1921, 1922. *Price* 140*s.*

The publication of the Annual Tables of Chemical, Physical and Technological Constants, which was discontinued during the war, has now been resumed with the issue of Volume IV, which includes all the scientific and technical data published in the years 1913, 1914, 1915, 1916. The Editorial Committee has had to overcome great difficulties and some still remain to threaten the continuation of its work, which is considered essential by scientists and engineers.

To provide support for the Committee, the International Union of Pure and Applied Chemistry decided to form an International Fund, and subscriptions from France and the United States have already furnished half the sum required. It is hoped that other countries will subscribe without delay, as the Committee would then be able to publish Volume V, for which the data, covering the years 1917 to 1922, have already been collected. The importance of such a collection of data becomes increasingly evident, especially as much of the information could otherwise be obtained only by detailed study of every scientific and technical periodical. Besides the names of practically every scientific establishment in the world, the list of subscribers includes those of firms representing the most varied branches of industry. The task of collecting and publishing such a large mass of information is particularly heavy, and only when the list of subscribers includes all those who *should* subscribe in their own interests, will the future of the Tables be assured. The two parts which constitute Volume IV are well printed in a reasonably clear type and are well bound. To Dr. Charles Marie, who has edited the Tables, the greatest credit is due for the publication of such a vast collection of accurate numerical data in orderly sequence and arrangement.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The general position shows a tendency for prices to firm up somewhat. This is undoubtedly due to an anticipated shortage of supplies from Germany as a result of the French occupation of the Ruhr and the probable shortage of fuel for industrial purposes. Should it become necessary for the Germans to import coal, cost of production will rise enormously, and even the tremendous depreciation in the value of the mark will render their competition in the British market practically unavailable.

Acid Acetic, 40% tech.	£21 per ton.
Acid Hydrochloric	4s. to 5s. carboy d/d.
Acid Nitric, 80° Tw.	£23 per ton. In rather small demand.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw., is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% arsenical	£6 10s. per ton.
Ammonia Alkali	£8 per ton. Home trade demand, which has recently been somewhat down, is showing slight improvement. Export in good demand.
Arsenic (White)	About £70. Demand still good and supplies very short.
Bisulphite of Lime	£7 per ton, packages extra and returnable.
Bleaching Powder	£10 10s.-£11 10s. per ton. Very slight improvement to report. Continental offers not quite so frequent and at rather higher figures.
Calcium Chloride	£6 per ton, carriage paid. No appreciable change—foreign offers still at low figures.
Copper Sulphate	£26 per ton f.o.b.
Potash Caustic	£29-£30 per ton. Not very much doing, but position shows signs of hardening.
Potassium Bichromate	6¼d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s.-£5 10s. per ton. Inquiry still good, with rather small inclination on the part of sellers.
Soda Caustic, 76%	£20-£21 per ton. Position somewhat improved at unchanged prices.
Soda Crystals	£5 10s. per ton carriage paid. Unchanged.
Sodium Bicarbonate	£10 10s. per ton carriage paid. In better demand both for home and export trades.
Sodium Bisulphite, 60/62%	£19-£20 10s. per ton f.o.b. or f.o.r. London.
Sodium Chlorate	Market dull, with offers of Continental make at low prices.
Sodium Sulphide	£16 per ton. Position unsatisfactory and demand very poor.
Sodium Sulphite, Pea Crystals	£17 - £17 10s., 1 - cwt. wooden kegs included.
Sodium Acetate, 97/98%	£23 per ton.
Sodium Nitrite	£30 per ton, 100% basis, d/d.

WOOD DISTILLATION PRODUCTS

There is a brisk inquiry for all products, and in most cases the demand is greatly in excess of production, consequently prices for some products show a sharp upward tendency.

Supplies of Wood Naphtha (to pass customs and excise regulations for methylating) are very scarce, and home prices have followed the American quotations, which are about 1s. per gallon less for prompt shipment than prices asked for stocks held in this country, or respectively 6s. 10d. and 7s. 10d. per gallon. Grey Acetate of Lime (80%) is also greatly in demand by both home and Continental users, the shortage being due to restricted imports from America and also to some extent to reduced output in this country. Some importers are asking as high as £19 10s. c.i.f., but most of the home makers have sold at considerably lower prices, as indicated in the "prices column," although prices of both the Brown and Grey qualities are tending upward, the former still showing a pro rata advantage to the user on the Acetic Acid content.

Considerable quantities of French Forest Burnt Charcoal are being offered and imported in competition with the more superior home-produced Retort Charcoal at varying prices, but recent shipments to Manchester worked out at £8 7s. 6d. per ton delivered buyers' works. Where high grade Charcoal is required, however, British producers have little trouble in selling at much higher figures.

Acetate of Lime, Brown	£9 per ton d/d.
Acetate of Lime, Grey	£15 10s. per ton d/d.
Acetate of Lime, Liquor	9d. per gall. 32° Tw. d/d.
Charcoal	£9 10s. to £10 per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15°Tw.
Wood Creosote	2s. 6d. ,, ,, Unrefined
Wood Naphtha, Miscible	7s. ,, ,, 60% O.P.
,, ,, Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£5 per ton d/d.
Brown Sugar of Lead	£36 per ton d/d.

TAR PRODUCTS

Acid Carbolic, Crude 60's	2s. 5d.-2s. 6½d. per gall. Market firm with fair inquiry.
Acid Cresylic, 97/99	2s. 2½d. per gall. Good business doing.
Acid Cresylic, Pale, 95%	2s. to 2s. 2d. per gall.
Acid Cresylic, Dark	1s. 6½d.-1s. 11d. per gall. Very little demand.
Anthracene Paste, 40%	7d. per unit per cwt. Price nominal; no business.
Anthracene Oil, Strained	8d. to 10d. per gall. Small inquiry.
Anthracene Oil, Unstrained	8d. per gall.
Benzole, Crude 65's	1s. 1d.-1s. 2d. per gall.
Benzole, Standard Motor	1s. 8d. to 2s. per gall.

Benzole, Pure	2s. to 2s. 2d. per gall. Small inquiry.
Toluole, 90%	1s. 10d. to 2s. per gall. Small inquiry.
Toluole, Pure	2s. to 2s. 4d. per gall. Small inquiry.
Xylol	2s. 6d. to 3s. 6d. per gall.
Creosote, Cresylic, 20/24%	10d. to 10½d. per gall. Fair business doing.
Creosote, Middle Oil	8¼d. per gall. Good business doing. Market strong.
Creosote, Heavy	8d. ,, ,,
Creosote, Standard Specification	7¾d. ,, ,,
Naphtha, Crude	9½d. per gall.
Naphtha, Solvent, 90/160	1s. 6d.-1s. 10d. per gall. Weak. Very little inquiry.
Naphtha, Solvent, 90/190	1s. 7d. per gall. Weak. Very little inquiry.
Naphthalene, Crude, Drained Creosote Salts	£6 to £7 per ton.
Naphthalene, Crude, Whizzed or Hot Pressed	£9 to £10 per ton. Good inquiry.
Pitch, Medium Soft	135s. to 140s. per ton. Market very firm and demand good.
Pyridine, 90/140	11s. 6d. to 12s. 6d. per gall.
Pyridine, Heavy	8s. to 9s. per gall. No business.

INTERMEDIATES AND DYES

Acid H.	5s. 1d. lb., 100% basis.
Acid Naphthionic	2s. 7½d. ,, ,, ,,
Acid Neville and Winther	6s. ,, ,, ,,
Acid Sulphanilic	1s. 6d. ,, ,, ,,
Aniline Oil and Salts	10d. lb., naked at works.
Benzidine Base	6s. 6d. lb., 100% basis.
Dinitrobenzene	11d. to 1s. lb., naked at works.
Dinitrotoluene, 48/50	8d. to 9d., naked at works
,, 66/68	1s. 2d. to 1s. 3d., naked at works.
Diphenylamine	4s. 1d. lb.
α-Naphthol	2s. 9d. lb.
β-Naphthol	1s. lb.
α-Naphthylamine	1s. 6½d. lb.
β-Naphthylamine	4s. 6d. lb.
p-Nitraniline	2s. 9d. lb.
Nitrobenzene	8d. lb., drums extra.
Nitronaphthalene	1s. lb.
Naphthionate Soda	2s. 8½d. lb., 100% basis.
Diethylaniline	4s. 6d. lb., packages extra.
Metanitraniline	5s. 6d. lb.
Para Toluidine	5s. lb.
Para Phenylene Diamine	12s. lb., 100% basis.
Meta ,, ,,	5s. 6d. lb.
Meta Toluylene ,,	5s. lb.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The prices of Pharmaceutical Chemicals are all distinctly firmer in the expectation that German competition may soon be eliminated for some space of time. It is possible that shortage of spot supplies of some chemicals may result in the prices going higher for a brief period.

Acid Acetic, 80%	£44 per ton.
Acid Acetyl Salicylic	2s. 10d. to 3s. lb. Price unchanged but distinctly firmer with good demand.
Acid Benzoic	2s. lb. still accepted for spot parcels, but it is difficult to book at this figure for forward delivery.
Acid Boric, B.P.	£61 per ton crystals, £65 per ton powder, packages in 2-cwt. bags; carriage paid U.K.
Acid Citric	1s. 6d.-1s. 8d lb. Market very firm. Considerable buying going on.
Acid Salicylic	1s. 5d. to 1s. 6d. lb. With a firmer tendency.
Acid Tartaric	1s. 2½d.-1s. 2¾d. lb., less 5% for minimum 1-ton lots. A further advance has taken place. The market is daily becoming firmer on increased demand and on progressive increase of cost of raw materials.
Acetanilide	1s. 6d. lb. Slightly less for quantity.
Amidopyrin	14s. lb. Firmer in view of smaller supplies being available.
Ammonium Benzoate	3s. lb. for best makes.
Ammonium Sulphocyanide	2s. 6d. for recryst.
Atropine Sulphate	12s. 6d. oz. Higher prices are expected to prevail before long.
Barbitone	12s. 6d. lb. In better demand.
Benzonaphthol	5s. lb.
Bismuth Salts	Prices per lb. for cwt. lots are as follows:—Carbonate 13s., Citrate 11s. 7d., Nitrate Cryst. 6s. 11d., Oxide 14s. 5d., Salicylate 10s. 3d., Subchlor, 12s. 8d., Subgallate, 9s. 6d., Subnitrate, 11s.
Bromides	Prices stiffening up owing to uncertain conditions on the Continent.
Calcium Lactate	2s. 6d. to 3s. 6d., according to quality and quantity.
Chloral Hydrate	4s. lb. for duty paid.
Guaiacol Carbonate	8s. 6d. lb. There is very little demand at the moment.
Hexamine	3s. 6d.-3s. 9d. lb. Very much firmer, with higher rates being quoted for forward delivery.
Homatropine Hydrobromide	30s. per oz.
Iron Ammonium Citrate	No change; rather quiet with small demand.
,, ,, ,, B.P.	2s. 5d. lb.
,, ,, ,, Green	3s. 1d. lb.
Iron Perchloride	22s. to 25s. cwt. Steady market.
Menthol	37s. 6d. lb., less 2½% for original cases. Smaller quantities 38s. lb. nett.
Methyl Salicylate	2s. 2d. unchanged, for good quality.

Mercurials	Unchanged. Market for quicksilver weaker.
Paraldehyde	1s. 6d. to 1s. 9d. lb. Spot supplies are short and higher prices must soon obtain.
Phenacetin	5s. lb. Still firm.
Phenazene	7s. lb. Price hardening upwards.
Phenolphthalein	5s. 6d. lb., with little offering.
Pilocarpine Nitrate ..	22s. 6d. oz.
Potassium Bitartrate 99/100% (Cream of Tartar)	98s. per cwt. for ton lots, less 2½%. Firm with upward tendency.
Potassium Ferricyanide ..	4s. to 4s. 3d., according to quantity.
Potassium Iodide	15s. 8d. lb. for cwt. lots. Cases free. Demand still good.
Potassium Metabisulphite	8d. per lb.
Potassium Permanganate ..	8½d. lb. for good quality.
Quinine Sulphate	2s. 3d. to 2s. 4d. oz. Bulk packages. Fairly steady market.
Salol	2s. lb., with higher prices probable in face of any demand.
Silver Proteinate	12s. lb.
Sodium Benzoate	2s. lb. Very firm in common with Acid Benzoic.
Sodium Citrate, B.P.C. ..	2s. per lb. for cwt. lots.
Sodium Potassium Tartrate (Rochelle Salt)	80s. to 85s. per cwt. Fair demand.
Sodium Salicylate ..	2s. powder, 2s. 1d. crystal. Prices are as yet unchanged, but very firm.
Sodium Sulphite, Anhydrous	£25 10s. to £28 10s., according to quantity; f.o.r. London, drums included.
Sodium Sulphite, crystals ..	£17-£17 10s. per ton, according to quantity.
Thymol	17s. to 19s. lb. Much firmer on withdrawal of some of the competition abroad for the synthetic article.
Ammonium Carbonate, B.P.	£37 6s. 8d. nett per ton.
Magnesium Carbonate, Light Commercial ..	£40 per ton.
Magnesium Oxide—	
Light Commercial ..	£85 per ton.
Heavy Commercial ..	£29 per ton.

PERFUMERY CHEMICALS

Amyl Acetate	2s. 3d.
Amyl Butyrate	8s.
Amyl Salicylate	3s. 3d.
Anethol (melting point 21/22° C.)	4s. 6d.
Benzyl Acetate from chlorine-free Benzyl Alcohol ..	3s.
Benzyl Alcohol free from chlorine	3s.
Benzaldehyde free from chlorine	3s.
Benzyl Benzoate, 19.5° C.	3s.
Cinnamic Aldehyde 98/100%, Natural ..	14s. 9d.
Citronellol	22s. 6d.
Citral, 100%	10s. 6d.
Ethyl Phthalate	4s. 3d.
Eugenol, 100%	11s.
Geraniol (from Palmarosa)	30s.
Geraniol	5s. 6d. to 12s. 6d.
Iso Eugenol	17s.
Linalol, ex Bois de Rose ..	21s.
Linalyl Acetate	22s. 6d.
Methyl Benzoate	8s. 6d.
Phenyl Ethyl Acetate ..	10s.
Phenyl Ethyl Alcohol ..	17s. 6d.
Rhodinol	45s.
Terpineol	3s.

ESSENTIAL OILS

Anise Oil, Red Ship Brand	2s. 1½d.
Bourbon Geranium Oil ..	20s. for shipment.
Cananga Oil, Java ..	9s. Firm.
Cinnamon Oil, leaf ..	4½d. per oz.
Cassia Oil, 80/85% ..	8s. 7½d.
Clove Oil	7s. 3d.
Citronella Oil, Ceylon ..	3s.
Citronella Oil, Java 85/90%	3s. 6d.
Eucalyptus Oil, 70/75% ..	1s. 10d.
Lavender Oil, Mont Blanc 38/40%	14s.
Lemon Oil, spot	2s. 10d. New crop for shipment 2s. 7d.
Orange Oil, sweet, spot ..	9s. 6d. New crop for shipment 8s. 3d.
Otto of Rose Oil—	
Anatolian	24s.
Bulgarian	28s.
Palma Rosa Oil	17s.
Peppermint Oil, English, Mitcham	80s.
Peppermint Oil, Mayne County	14s.
Peppermint Oil, Japanese ..	7s. 6d.

TRADE NOTES

London Joint City and Midland Bank, Ltd.

The Ordinary General Meeting was held on January 2[illegible] 1923. The Right Hon. R. McKenna (Chairman) said that our commerce is distinguished from that of any other country by its large proportion of foreign trade, which, it is safe to say, before the war absorbed one-third of the labour of our people, whether in production, transport, or clerical work. It appears that though our Imperial trade has suffered less than our foreign trade, it has still been greatly impaired, and so far from reducing our loss has itself contributed to it. The relations between capital and labour are on a far better footing than they were two or three years ago. Post-war illusions have been dispelled and there is a general disposition to face realities. The public has a wider recognition of the necessity for national economy, of the crushing effect of excessive taxation on industry, and of the need for greater production. If we look for a revival of trade, for more abundant revenue and for a reduction in taxation, we must leave prices to take their own course under the normal pressure of supply and demand and must seek a general increase of wealth through a more abundant output.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, FEBRUARY 9, 1923 No. 6

EDITORIAL

WE are not ashamed to confess that we have only a very indistinct idea of what an Editorial should be and why such notes are published in weekly journals. The leading articles in a daily newspaper, which are perhaps the ancestral type of this sort of writing, are usually better written, better printed and much shorter, than the news which deals in detail with the particular topic. They therefore often save the busy man the trouble of reading a couple of columns of small print. In the case of our *Journal*, they can hardly be anything more than brief comments on subjects which happen to come before the editor in the two or three days which precede the printing and publication of the issue. They must be the most ephemeral part of the reading matter, merely a polite and conventional invitation to the reader to begin, so soon as he feels inclined, to read the *Journal* itself. They are perhaps comparable to the speech of the chairman who introduces a lecturer in a few preliminary observations. If our experience is a guide, the audience is very tolerant, even kindly disposed, to a chairman whose speech is brief. How we have all suffered from the chairman who has spoken for a quarter of an hour and then racks his brains for an elegant phrase with which to end his peroration, trying first one and finding it not to his satisfaction, then trying another, wearying with these efforts the listeners who would be only too thankful if he stopped in the middle of a sentence or, better still, in the beginning of it! The writer of such introductory paragraphs should not let trifles stand in the way of his duty, this being to make the reader speedily welcome some piece of news or well-written article. Undue attention to trifles often hinders the real work. " He that observeth the wind shall not sow, and he that regardeth the clouds shall not reap."

* * *

It was a wise man who stated : " There are two kinds of things it is no use complaining about : the things that can be helped and the things that can't be helped." We fancy that Dr. Scott must be some such philosopher. He received some years ago from a friend a sample of sand from New Zealand, analysed it and found what he thought was an oxide of a new metal ; waiting for that leisure, which is so elusive, he kept the sample and its solutions, hoping to turn his attention to it at an early date. Before he could find a convenient opportunity, other workers, engaged on accurate X-ray analysis, announced the occurrence of lines which could only belong to some such metal. Without a word of regret at this prior announcement, with no complaint of hard luck, Dr. Scott speedily completed his analysis, prepared a double fluoride of the new element and potassium, determined approximately the atomic weight of the new element, as announced before the Chemical Society and reported in our present issue, offered a sample of the new oxide to the other workers, Professors Coster and Hevesy, which offer has been gratefully accepted, and is now engaged with the small residue of his material in making a more complete investigation of the new element and its compounds. The new element has some of the properties of the titanium group : for instance, its capacity for forming double fluorides, and it is interesting to note that this double fluoride is hygroscopic ; it might have been expected it would have more affinity for water than the corresponding compounds of titanium and zirconium. Titanium was named from the Titans, one of whom was Oceanus, and Dr. Scott proposes for the new element the name Oceanium, as being of the same class as Titanium and not so purely local as Hafnium, or Celtium, the alternatives proposed by some of the other applicants for the vacant space in the list of atomic numbers. It is a pity that the name of Moseley, the pioneer in X-ray work, does not lend itself to this sort of nomenclature, whilst Scotium is more suggestive of Celtium than is reasonable in the circumstances. To those of us who were born south of the Tweed it is a little disconcerting that the elements recently discovered by British chemists should so many of them be claimed by Ramsay and Scott; this belongs to the category of things that can't be helped, and we must be as philosophic as Dr. Scott. There are only very few elements left to discover, and we beg Dr. Aston, Professors Perkin, Wynne and others to claim some of these for England before it is too late.

* * *

The paper by Dr. Fyleman read before the London Section of the Society of Chemical Industry on the 5th inst., had already been published in full in our Transactions of January 26. This experiment in premature publication, combined with the interesting character of the topic, led to a capital discussion, and those who are responsible for organising such meetings might well consider whether an early distribution of prints of an important paper might not be very helpful. In this particular case the Author dealt with a number of explosions which had occurred in the distillation of liquid air and various explanations were suggested as to the possible origin of these through the accumulation of solid acetylene, perhaps assisted by an electric spark. The American Chemical Society has quite recently published some curious cases of gas and other explosions which show how unexpected may be the influences which bring about such disasters. A Naval Surgeon walked to his garage in rubber boots and a fur coat, the friction of which generated enough electricity to cause an explosion of petrol and air which destroyed his motor car. When petrol is pumped through a hose or through a skin or chamois strainer a high voltage is generated. But perhaps the most unlikely cause of an explosion is that described by the New York Society for the Prevention of Cruelty to Animals, who have been in the habit of asphyxiating stray cats in large numbers. There have been half-a-dozen minor explosions and one serious one caused by dropping a basket full of cats into ordinary illuminating gas. Electricity was generated in sufficient quantity to explode the gas in contact with air. We refer our readers to a communication from Mr. A. H. Gill of The Massachussets Institute of Technology in the February number of *Industrial and Engineering Chemistry.*

CHINA CLAY

Its Composition, Preparation and Uses

By H. F. COLLINS, A.R.S.M., M.I.M.M.

(*Continued*)

At first sight, the method of drying may appear primitive, but when it is considered that the objective is the complete elimination of water from a sludge or slurry containing 50 per cent. of that substance, without running any risk of damaging the colour of the product by overheating, contamination with iron, or with the products of combustion, the finding of an alternative to the present system is seen to be not a simple matter. Filter-pressing the sludge reduces its water content from 50 per cent. to 25 per cent., but the elimination of the remainder requires more than half the fuel necessary for the original content of 50 per cent., and even the saving in fuel that is realised is largely offset by increased cost for labour, power, and wear and tear. Strict regulation of the combustion in the furnaces of the "drys," eliminating on the one hand imperfect combustion with production of smoke and of carbonic oxide, and on the other, circulation of surplus air through the fire boxes, which was formerly the greatest source of excessive consumption, has in the best practice reduced the consumption of fuel to not much more than one-half its former proportions, and in actual practice, with coal of good quality and under good control, clay is being dried with a consumption of only 8 to 9 per cent. of fuel. For this it is necessary to employ furnaces with closed ashpits, the whole of the air supply being preheated by passage through the brickwork, and regulated in quantity; to use an auxiliary air supply over the bridge after firing up; and to have automatic carbon-dioxide recorders in the flue at the base of the stack.

Much has been heard from time to time of the purification of clay by centrifugal separation from sand and mica, and by electrolytic separation of impurities such as iron and titanic oxides. Prevention is, however, better than cure, and whilst many foreign clays are much improved in colour and quality by electrolytic separation, the greater part of our own West of England clay is already so free from these particular impurities that such refinement is unnecessary because unwarranted by the market demand, whilst as regards our "common" clays (the bulk of which are inferior to the "medium" quality or "seconds" clays only in possessing a cream or yellowish tinge) the amount of improvement that can be effected by such methods does not seem likely to compensate for the additional cost. The yellow colour of common clays is generally, though by no means invariably, due to the presence of iron oxide. Sometimes, however, it is due to some form of organic matter, which disappears upon "firing," leaving the clay dead white.

Uses of China Clay

The two principal uses of china clay are for paper-making and pottery. During the pre-war period. less than one-third of the total output was employed for the latter purpose, by far the largest individual use of the material being for paper-making. Other uses are :—

(1) As a stiffener, mixed with size, for loading cotton cloth and other textile fabrics. Clays for this purpose, like those used for paper-making, are known as "bleaching" clays.

(2) For the manufacture of sulphate of alumina, and of alum ; the more aluminous varieties are naturally preferred for this purpose.

(3) For the manufacture of ultramarine. In Germany alone from 12,000 to 15,000 tons are said to have been used for this purpose before the war, but the trade seems to have shrunk to minute dimensions since.

(4) As an absorbent and loading material in the manufacture of linoleum, papier maché, and white celluloid goods, also of tyres and other rubber goods, and of modelling materials.

(5) In the manufacture of special wall plasters and distempers (particularly in the U.S.A.) ; also for tooth and toilet powders, cleansing soaps, coloured chalks and crayons, etc.

(6) For the adulteration of whiting, and of various zinc and lead mixed white pigments and of plaster-of-paris, and as a filler to give body and weight to asbestos and other packings, also as a simple adulterant to chemical manures and to certain articles of food that are sold in powdered form.

In paper-making, china clay, mixed with size, performs the function of filling the pores or voids between the shreds of pulped vegetable fibre that form the grain or skeleton of the paper, giving it body as well as a solid even surface. For best quality paper, the whitest and best grades of china clay are always preferred, colour being added to suit when making cream or azure papers, not only because the colour is in that way under better control, but because the whitest clays are also the finest, and therefore keep in suspension better. For newspapers and other paper of lower class, a common grade of clay can of course be used.

Sometimes, in paper-making, two qualities of clay are employed, a low medium clay, provided its grain be fine enough, being used for the body of the paper (called "loading" clay), whilst the half-finished paper is passed through a bath of high quality fine and white clay (called the "coating" clay) mixed with size, and then between hot rollers in order to give it a smooth and glossy white surface. Such coated paper is employed for making paper for process blocks, etc., and for other purposes.

The distinction between "potting" and "bleaching" clays (*i.e.*, those used for paper-making and for loading textile fabrics) is by no means definite, or based upon any characters that lend themselves to specification. In general, bleaching clays must be fine-grained, so that they show but little tendency to settle out from the emulsion-like baths into which they are made up ; also they must be of best to medium colour, according to the exact use to which they are put.

The colour of common and medium quality clays, for so-called "bleaching" purposes, is often improved by judicious "blueing."Aniline blue, mixed in a barrel with water, is allowed by means of a syphon to drip in any desired proportion into the stream of purified clay water on its way to the settling-pits. The capacity of china clay for absorbing pigments is so great that the perfectly soluble dye is all taken up by the deposited clay, leaving the overflow water as free from colour as if no dye had been used. The best clays, of course, are of a dead white colour without any such extraneous assistance, but occasional stained sections of a pit that ordinarily yields best clay can be brought up to standard by this means, whilst the distinctly yellowish tinge of "low medium" clays is often counteracted in this way sufficiently to improve their selling price considerably.

As to the "potting" clays, their colour in a raw state does not so much matter so long as they "fire" white. As a general rule clays are preferred for potting that settle fairly rapidly ; speaking generally therefore, their particles may be coarser than those of the clays best suited to paper-making. Potting clays often contain somewhat larger quantities of alkalis and alkaline earths than do the bleaching clays ; such impurities, which increase the tendency to frit at a very high temperature, improve their quality for pottery purposes. China clay of any possible composition will give good results in potting provided the other ingredients are varied to suit. Pottery formulæ, however, are purely empirical, foremen and workmen are dominated by custom and by infinite unconscious prejudice, and so it happens that one particular brand of china clay is preferred to another quite as good or possibly better, simply because there is no one willing to risk making the slight change in the formula required to compensate for a slight difference of composition, or unprejudiced enough to survey the results of a change without bias.

Speaking generally any clay which is sufficiently white and fine-grained will fetch a better price for paper-making than for potting, but many clays which are not white enough for high-class paper nor sufficiently fine-grained, provided they "fire" white, are in good demand as potting clays.

Electrolytic Purification

Upon the Continent of Europe clay intended for the manufacture of high-tension insulators is freed from iron and titanium oxides (the principal harmful impurities) by passing a continuous current of electricity at from 60 to 100 volts through the slowly moving stream of clay slip flowing through a trough of semicircular section, the anode being a metallic drum revolving slowly within the trough, while the cathode is a half-cylinder of wire netting suspended concentrically and only half an inch below. The iron and titanium oxides, being electropositive, collect below the wire netting, whence they are removed by a worm discharge, whilst the purified clay, being electronegative, attaches itself to the surface of the drum, whence a fixed knife removes it in the form of a slab about half-an-inch thick.

It has been suggested that the yellowish colour of inferior Cornish clays could be so much improved by such treatment as to enable them to be graded as of much higher quality. It does not appear, however, that the probable improvement likely to result in the colour of the clay will be sufficient to compensate for the additional cost of the process.

Foreign Competition

An impression seems to prevail in many quarters supposedly well informed that china clay is a product peculiar to Cornwall and Devon, and not found anywhere else. It is true that most of the so-called "kaolin" produced in the United States is of detrital origin, like the "ball clays" of Devonshire and Dorsetshire, and cannot be compared with English china clay either for colour or for uniformity of fineness. Even in the United States and Canada, however, and to a greater extent in France, Bohemia, Denmark and Spain, deposits are to be found of granite, gneiss or felsitic rock, the felspathic constituent of which has been, like those of the West of England, kaolinised *in situ*. As regards quality, whilst foreign methods of mechanical preparation are rarely carried out so thoroughly as with us, neither do the same facilities exist for cheap working, some of the French, Bohemian and Saxon deposits yield upon washing a product quite equal in colour and fineness to our own. The pre-eminence of the West of England output of china clay is due to the following factors :—

1. Large size of the deposits, and their extension over comparatively wide areas close to surface with but little "cover."
2. Methods of mechanical purification that are at once simple, inexpensive, and thorough, securing uniformity of product.
3. High average quality and colour as compared with the average product from any other district.
4. Proximity to shipping ports and the convenient situation of these for outward bound ships in search of a convenient "ballast" cargo.

Best "bleaching" clays from Cornwall and Devonshire are sent all over the world for paper-making, even to countries like France, Germany and the United States, which have fairly good domestic sources of supply. This is partly because of their great natural uniformity of character, partly because, being water-borne, they can compete within very wide limits of space with the domestic clays that have to be sent long distances by rail, as for example from the Southern States to Chicago or other Western centres. In spite, therefore, of the improvements that are gradually being effected in the mechanical preparation of foreign clays, it seems probable that British china clay will continue to assert and maintain its pre-eminence, and that the export trade will gradually return to its former dimensions, except possibly that to the United States. This recovery, however, must of necessity be a slow process, dependent upon the general recovery of trade, and it will be a long time before sales can overtake productive capacity.

Output and Profits

During the 20 years before the war, the output of china clay had shown a fairly steady increase from 425,000 tons in 1895 to 860,000 tons in 1912 and 1913, whilst during the first half of 1914 the sales amounted to 500,000 tons, or at the rate of one million tons per annum. Of this total between 75 and 80 per cent. was exported to foreign countries, the chief individual consumer being the United States, with a consumption which had risen steadily from 65,000 tons in 1895 to 335,000 tons in 1914. The war, with its scarcity of tonnage and high freight rates, cut down the export trade to very small dimensions, foreign countries being thus forced to develop to the utmost their native sources of supply, which are in many cases abundant, though generally of inferior quality. In view of this development of native supplies it seems doubtful whether exports to the United States will ever again reach the high-water mark of the years just before the war.

After the war there was a rapid increase in exports, mainly with a view to replenishing vanished stocks abroad, but this was followed by a slump, from the effects of which the industry is only now recovering. Really accurate figures in regard to output, sales and export are not obtainable ; the Government statistics in regard to export in particular being most misleading, since ball clay and lump and ground china stone are all included with china clay in one general total without distinction, a fact which renders these statistics absolutely useless to those interested in the industry.

As regards actual deliveries during the past three years, information furnished confidentially to the writer leads him to put forward the following figures, which he believes will be found to be close approximations to the truth, viz. :—

	Tons
1920	770,000
1921	370,000
1922	670,000

Seeing that the actual output for the first half of 1914 was at the rate of one million tons per annum, the above figures show that, in spite of the recovery in 1922 from the depression of 1921, which certainly represents a real improvement, the output of to-day is still far short of that of the pre-war period. This, however, does not tell the whole story. During 1914 many extensions of drying plants were in course of erection, and a good many new ones have been completed since, so that the total productive capacity of the industry, as measured by drying capacity (the accepted standard), must be at the present time very nearly 1¼ million tons per annum. Owing, therefore, to the limited demand, the actual output of china clay is still only about 55 per cent. of the total productive capacity of the existing plants. In view of the many misleading statements recently published in regard to the great improvement in the trade, and its prosperous condition, it seems desirable to draw attention to the undoubted fact that the plant and equipment at present employed in the industry is far from being fully utilised.

As to prices and profits, the principal controlling interests seem to have realised that the only hope of regaining the markets lost during the war period is to reduce the selling prices to the lowest point possible. The present selling prices, however, are still so far in excess of the pre-war prices (at which good profits were made) that some have jumped to the conclusion that producers must still be making large profits. This is by no means the case at present, for the costs of production have increased at a greater ratio than have the selling prices.

In the first place, comparing the year 1921 for instance, with 1914, the standing charges at a clay works remain at about the same level whatever the output. Salaries of officials, and the cost of maintaining the shafts, levels, pumps and other plant suffer little or no reduction even if the works stand idle all the year. The surface and coming spring water has to be pumped in any case, and considerable expense is often caused in an idle pit through slipping in of material from the sides. All these costs are on a much higher basis than in 1914, perhaps on the aggregate nearly double, and upon one-half or less of the full capacity the aggregate cost of these standing charges per ton of clay produced and sold is nearly four times as great. Minimum rents are in some cases so high that they only merge in the royalty when the pit is being worked at more than half the full capacity. Local rates, too, have gone up enormously.

As regards operating costs proper, all are much higher absolutely, apart from any question of working at below full capacity. Coal for pumping and for drying, which forms a considerable proportion of the total operating cost, although coming down in price, is still much dearer than in the pre-war period: its average price during the years 1921–1922 may be taken at about double that of the pre-war period 1913–1914. Even a greater discrepancy is to be noted in regard to the wages part of production cost, although not all of this is apparent. Not only does the current rate of wages paid in the industry rule higher than in the pre-war period, but there is some falling off in efficiency. Up to 1916 the district had been characterised by its free labour. About that time (entirely through the agitation of organisers from outside, who were paid agents of a trades union anxious to increase its membership and its political influence) branch unions were started in the district, and soon the whole of the workers became members of the union in question. The usual consequence followed, (although as usual stoutly denied by the union officials and sympathisers), namely, that efficiency, or the work done per man, showed a serious falling off. The union has ceased to have any influence in the district as an active factor in the labour problem, but the falling off caused by its former influence has not yet been completely made good.

Upon the whole, therefore, as a consequence of all the various reasons enumerated, the rise in working costs has kept far ahead of that in selling prices, as compared with the pre-war period; and the margin for profits in the industry will remain somewhat small until the condition of the world, and particularly of Central Europe, approaches more closely to normality, and until output begins to catch up productive capacity.

THE CALCIUM CARBIDE INQUIRY

By SIR WILLIAM J. POPE

Part II

THE conception of an organic compound which prevailed until well into the nineteenth century was well expressed by Buffon: "A living organic matter exists, universally distributed throughout all animal and vegetable substances, which is essential equally to their nutrition, their development and their propagation" (Histoire des animaux, 1836, vol. 4, page 52). The abandonment of such a fundamental distinction between inorganic and organic chemistry as is involved in this statement left a need for an empirical subdivision and, as has been already shown (this Journ., p. 5), a majority of the foremost contributors to the development of organic chemistry agreed to include as organic compounds "the compounds of carbon generally; a small minority of such chemists exclude from their definitions, carbonic oxide, carbonic anhydride and the salts of carbonic acid with inorganic bases. No other compounds of carbon are excluded from the definition by any organic chemist of repute."

The desire of the few to exclude carbonic oxide, carbonic anhydride and the metallic carbonates from the list of organic compounds arose largely from the wide distribution of these substances and their importance to others than purely organic chemists; it led Schorlemmer to "define organic chemistry as the chemistry of the hydrocarbons and their derivatives" (Definition 14, page 6). This definition does not really make for logical unity because carbonic anhydride, which it designs to exclude, is as intimate a derivative of methane as oxalic acid is of ethane, and both the latter are admitted to be organic compounds. It will now be shown, however, that Schorlemmer's definition, which was advocated by several of the expert witnesses called during the calcium carbide hearing, leaves the latter substance without doubt in the category of organic compounds; further, that an even more narrowly limited definition which was quoted, to the effect that an organic compound is one which contains a hydrocarbon radicle, still includes calcium carbide as an organic compound.

The term "derivative" as used in organic chemistry has had a curious history. It was first liberally applied by Berthelot, in accordance with a well-known philological rule in the Latin tongues, to any substance derived or prepared from the subjective substance; thus, he spoke of ethylene dichloride as a derivative of ethylene and of monochloroethylene as a derivative of ethylene dichloride (Chimie organique, 1860, vol. 1, page 219) and of "derivatives formed by addition, elimination and substitution" (Méthodes générales de synthèse, 1864, page 506). In later days he restricted the term "derivative," in general, to substitution products (La synthèse chimique, 1883). Frankland very rarely used the word, and when he did was careful to indicate clearly by a formula the closeness of relation to which he referred (compare Phil. Trans., 1856, **147**, 59); the contents pages of the "Ansichten über die organische Chemie," of 1881, show that van't Hoff's lavish use of the term was always accompanied by a precise indication of the degree of relationship concerned. In German the word derivative is only occasionally met with, and then almost always with a prefix indicative of the kind of substitution concerned; in Graebe (Geschichte der organischen Chemie, 1920) the word only occurs a few times, and in each case, with a suitable prefix, as synonymous with substitution product.

Without discussing further the subtle variations in usage of the qualitative term "derivative," which requires to be quantified before it acquires an intrinsic meaning, it is submitted that if calcium carbide can be shown (1) to be acetylene in which the two hydrogen atoms are replaced by the equivalent bivalent atom of calcium, and (2) to contain the hydrocarbon residue, —C ⋮ C—, which is the characteristic bivalent acetylene radicle, it will be included by all the definitions of any weight. The experimental evidence bearing on these points is very complete, although little of it was revealed during the inquiry.

Direct Evidence of the Constitution of Calcium Carbide

When calcium carbide is kept for several months in contact with excess of bromine, calcium bromide and perbromoethane are obtained in almost the yields indicated by the equation :—

$$\mathrm{Ca}\Big\langle\overset{C}{\underset{C}{|||}} + 4\,\mathrm{Br_2} = \mathrm{CaBr_2} + \mathrm{CBr_3.CBr_3}$$

(Barnes, *Chem. News*, 1919, **119**, 260). This reaction, proceeding slowly and practically quantitatively in the absence of water, is convincing proof that the calcium carbide molecule contains two atoms of carbon joined by the triple acetylene bond; if this is not agreed, and it was contested at the hearing, it must be admitted that organic chemistry possesses no methods for determining molecular constitution.

Another argument, a little more involved but quite as definite, which was not produced during the enquiry, may be now stated.

The Constitutions of the Metallic Carbides

The metallic carbides are numerous and may be classified in a manner which reveals the existence of simple relationships between their types of molecular composition, and therefore constitution, and their chemical behaviour. For purposes of illustration a few types may be distinguished and the type reactions described.

Type 1—This is represented by silicon carbide, SiC, which is chemically a very inert substance.

Type 2—This is represented by manganese carbide, Mn_3C, and ferrous carbide, Fe_3C. In the most simple molecular compositions ascribable to these substances, one atom of the quadrivalent element carbon is associated with three atoms of the bivalent metal. Brame and Lewes showed (J. 1902, **21**, 755) that the following hydrolysis occurs :—

$$Mn_3C + 6\,H_2O = 3\,Mn(OH)_2 + CH_4 + H_2.$$

The hydrolysis of ferrous carbide does not proceed so simply, but it is clear that carbides of this type are not simply related to acetylene.

Type 3—This is represented by aluminium carbide, Al_4C_3, and beryllium carbide, Be_4C_3, in which four atoms of a tervalent metal are associated with three atoms of the quadrivalent element carbon. Both carbides yield methane with water, and Matignon has shown (Comptes rendus, 1907, **145**, 676) that the following reaction occurs :—

$$Al_4C_3 + 12\,H_2O = 3\,CH_4 + 4\,Al(OH)_3.$$

It is evident that carbides of this type are closely related to methane; they are certainly not simple derivatives of acetylene.

Type 4—This is represented by all those substances the composition of which corresponds to that of acetylene, C_2H_2, in which one or both univalent hydrogen atoms are replaced by an equivalent number of atoms of a univalent or a bivalent metal. Such a limitation of molecular composition permits only the following four varieties of constitution; in these M' represents an atom of a univalent metal and M'' an atom of a bivalent metal. In each case actual compounds are quoted as examples:—

A $M'HC_2$. Represented by sodium diacetylide, $NaHC_2$, rubidium diacetylide, $RbHC_2$, and lithium diacetylide, $LiHC_2$.

B $M''(HC_2)_2$. Represented by calcium diacetylide, $Ca(HC_2)_2$.

C M'_2C_2. Represented by sodium, lithium, silver and cuprous monoacetylides, namely, Na_2C_2, Li_2C_2, Ag_2C_2, and Cu_2C_2.

D $M''C_2$. Represented by calcium monoacetylide, CaC_2, and strontium monoacetylide, SrC_2.

It will now be shown that only those compounds included in the four groups, *A*, *B*, *C* and *D*, which constitute the general type 4, are metallic derivatives of acetylene; they thus differ in constitution from compounds of the general types 1, 2 and 3, which may now be dropped out of the discussion. The argument is as follows:—

The metallic diacetylides and monoacetylides are produced as the result of, and are subject to, a number of general reactions. These reactions are numerous, and some of the individual acetylides are not known to obey all of them. But since each acetylide is involved in several of the class reactions, no doubt can persist that all are of identical chemical type of constitution; it will be seen ultimately that the acetylides are thus necessarily formulated as metallic derivatives of acetylene.

REACTIONS OF FORMATION OF CERTAIN METALLIC ACETYLIDES

a $2\,M'+2\,CH\vdots CH=2\,M'.C\vdots CH+H_2$.
b $M'H+CH\vdots CH=M'.C\vdots CH+H_2$.
$M''H_2+2\,CH\vdots CH=M''(C\vdots CH)_2+H_2$.
c $2\,M'+2\,C=M'.C\vdots C.M'$.
$M''+2\,C=M''C_2$.
d $2\,M'NH_3+2\,CH\vdots CH=2\,M''.C\vdots CH+2\,NH_3$ $+H_2M''(NH_3)_2+2\,CH\vdots CH=M''(C\vdots CH)_2+$ $2\,NH_3+H_2$.
e $2\,M'.C\vdots CH=M'.C\vdots C.M'+CH\vdots CH$.
$M''(C\vdots CH)_2=M''C_2+CH\vdots CH$.

The above reactions apply in the following cases:—

a When M' sodium or potassium.
b ,, M' is Na, K, Rb, Cs.
,, M'' is Ca.
c ,, M' is Li.
,, M'' is Ca, Sr or Ba.
d ,, M' is Li, Na, K, Rb or Cs.
,, M'' is Ca.
e ,, M' is Na, K, Rb or Cs.
,, M'' is Ca.

It is thus seen that all the substances classified under type 4, in which the type composition is that of acetylene in which one-half or all the hydrogen is replaced by an equivalent number of atoms of a univalent or a bivalent metal, are connected by a series of reactions. Each reaction is not yet known to occur in connexion with the acetylides of all the alkali and alkaline earth metals, but each occurs with a number of them. The reactions are thus type reactions of a set of compounds containing one element of constitution in common; if it can be proved that one of the compounds contains the acetylenic radicle, $—C\vdots C—$, it will follow that all contain the same constitutional element and are therefore metallic derivatives of acetylene containing this hydrocarbon radicle. A ready proof is available, as will be seen below, that sodium diacetylide corresponds to the latter description and has the constitution $NaC\vdots CH$.

All the compounds classified under type 4 yield acetylene on hydrolysis, those containing an alkali metal or an alkaline earth metal on treatment with water, those containing silver or copper when treated with acid. During the hearing it was suggested that the evolution of acetylene when water is added to calcium carbide is an "accidental circumstance" which had led to the erroneous conclusion that calcium carbide is a derivative of acetylene; the fact that all substances of type 4 undergo hydrolysis in the same way effectually disposes of this ingenious notion. Whilst it was apparently agreed that silver and cuprous acetylides are true metallic derivatives of acetylene, it was suggested that their stability towards water indicates that they differ in constitution from calcium carbide; but much greater divergences in behaviour are commonly to be observed between compounds which are admittedly metallic derivatives of the same hydrocarbon. Thus, zinc methyl, $Zn(CH_3)_2$ is spontaneously inflammable in the air and reacts violently with water giving methane and zinc hydroxide, whilst mercury dimethyl, $Hg(CH_3)_2$, is stable in the air and towards water, and only gives methane when boiled with acids.

PROOF THAT SODIUM DIACETYLIDE HAS THE CONSTITUTION, $NaC\vdots CH$

When sodium diacetylide, $NaC\vdots CH$, is treated with carbon dioxide under pressure, it becomes converted into the sodium salt of propiolic acid, $HC\vdots C.CO.OH$ (Skosarewski, Chem. Centr., 1904, ii, 1024). This reaction by which a hydrogen atom in an organic compound is replaced by a carboxyl group, .CO.OH, is frequently observed in organic chemistry; its occurrence with sodium diacetylide is proof that the acetylenic element of molecular structure is present in the substance and that this compound is therefore a derivative of acetylene.

Lebeau and Picon (Comptes rendus, 1913, **156**, 1077) have shown that sodium diacetylide dissolved in liquid ammonia obeys the following reactions with methyl iodide and with butyl iodide in the cold :—

$$NaC{\vdots}CH+CH_3I=NaI+CH_3.C{\vdots}CH, \text{ and}$$
$$NaC{\vdots}CH+CH_3.CH_2.CH_2.CH_2I=$$
$$NaI+CH_3.CH_2.CH_2.CH_2.C{\vdots}CH.$$

Picon further showed that the butene, $CH_3.CH_2.C{\vdots}CH$, is formed by the action of ethyl iodide or bromide on sodium diacetylide (Comptes rendus, 1914, **158**, 1184), and that the pentene, $CH_3.CH_2.CH_2.C{\vdots}CH$, is produced in a similar manner from propyl iodide (Comptes rendus, 1914, **158**, 1346). He described later analogous reactions in which ethylenic hydrocarbons are produced (Comptes rendus, 1919, **168**, 825).

The proof is, therefore, complete that sodium diacetylide, $NaHC_2$, is a sodium derivative of acetylene, and that its constitution must be represented as $NaC{\vdots}CH$. It is thus again demonstrated that calcium carbide is the calcium derivative of acetylene and that it contains the acetylenic hydrocarbon radicle, $—C{\vdots}C—$.

In his decision, the Referee commented on the fact that several definitions of an organic compound had been proffered; he quoted "compounds of carbon" without and with certain exceptions, the latter qualification referring to the erroneous translation of a German definition to which he attached considerable weight, "hydrocarbons and their derivatives" and "compounds of carbon which contain an organic radicle." It is now clear that calcium carbide conforms to all the important definitions of an organic compound.

Several curious objections were raised against the inclusion of calcium carbide as an organic compound. It was suggested that if its molecular weight corresponded to the formula CaC_2, it should be a low boiling liquid; the futility of this objection is obvious from the fact that cuprous acetylide, admittedly a derivative of acetylene, is not a low boiling liquid, and gold, the molecular weight of which is that of the atom, boils at a very high temperature.

The tribunal, having failed to elicit the fact that organic chemists are all but unanimous in their definition of an organic compound, exercised itself in the search for other criteria of this well-characterised entity. Surprise was expressed at the contention that calcium carbide is an organic compound in view of its stability towards heat, and the expert witnesses were asked to name examples of similar stability; curiously enough, the obvious instance, which was under discussion the whole time, was never quoted. The equilibrium mixture of gases obtained by heating carbon in hydrogen at 1700° contains a trace of acetylene, and the proportion rises to about 3 per cent. at 2800° (Pring and Hutton, Chem. Soc. Trans., 1906, **89**, 1591); at the temperature of the electric arc, namely, 3500° to 3750°, the equilibrium mixture, starting with hydrogen, methane or acetylene, contains roughly 86 per cent. of hydrogen, 3 per cent. of methane, and 9 per cent. of acetylene (Bone and Jerdan, Chem. Soc. Trans., 1897, **71**, 41). The stability of acetylene towards heat thus increases steadily up to towards 4000° and thermodynamic reasons exist for believing that the optimum point has not even then been attained. Calcium carbide,on the other hand, decomposes into carbon and calcium in a well-heated electric furnace (Moissan, Comptes rendus, 1898, **126**, 306) and, since metallic calcium readily volatilises in an electric furnace under reduced pressure (Pohl and Pringsheim, Ber. physik. Ges., 1912, **14**, 506) it would seem that the decomposition temperature of calcium carbide should be near the boiling point of calcium.

The experimental evidence thus indicates that acetylene itself is the most stable organic compound known towards heat, and that it is more resistant against heat than is calcium carbide; in fact, very few inorganic compounds withstand heat so well as acetylene.

In parts I. and II. of this series of articles it is claimed that calcium carbide has been proved to be an organic compound, the calcium derivative of acetylene, and to contain the acetylenic hydrocarbon radicle; in part III. it will be shown that calcium carbide is a synthetic compound.

NOTES FROM HEATHFIELD

By the Rector, Rev. B. V. WHITE, M.A.

Dear Mr. Editor,—The Parish of Heathfield lies in the County of York, about a dozen miles to the north of Harrogate. Being very large and extensive, it abuts on many other parishes, as Pateley Bridge, Blubberhouses, Appletreewick, and Ramsgill. The soils and rocks of this district are almost as various and diversified as the views and aspects. The high part to the west consists of a vast hill of limestone, rising to a height of some fourteen hundred feet above sea-level; this is capped in some places by a thin stratum of shale, and in some others by a layer of millstone grit which forms bold crags, standing out sharply on the sky-line. The lower slopes of this hill are well wooded with ask, oak, and sycamore. The bottom of the valley is only some four hundred feet above sea-level, and the little river has wandered about in days gone by and made a wide strath of fertile meadows and pastures. From all the slopes of the hill, and particularly from Red Brae, there is a very engaging view, an assemblage of hill, wood and moorland, with the river winding its silvery course among the farms and byres in the dale. From the top of the hill there is a vast prospect of all the mountains of Craven and the West of Yorkshire. You may see in fair weather the lovely valley of the Wharfe with Simon Seat, Great Whernside and Hawkswick Clouder, and from the crags on the adjoining moor, which rises yet higher, you may gaze on Penyghent and Pendle Hill and Little Ingleborough, as the old rhyme names them. My rectory stands in a pleasant situation near a purling beck or stream; it is well shaded by sycamore trees, and has an agreeable garth where many herbs and vegetables flourish. A plantation of spruce and larch shelters me from the north and north-western gales.

The population are a hardy folk engaged in farming; in the lower parts cattle are reared, but on the short sweet grass of the limestone pastures the half-bred moorland sheep flourish exceedingly, and these roam also on the rough heather of the millstone grit, sharing the solitude with the golden plover, the peewit, the curlew, and the grouse. You might imagine that in so pastoral and primitive a place, so far removed from the busy hum of men, I should have few opportunities of pursuing the studyof chemistry, which has long been a favourite diversion of mine, but I find abundant opportunities of seeing how, even here, chemistry plays its part in our lives, and with your permission I will set down in writing some of my reflections on this science.

It has been my misfortune never to have had any neighbours whose studies have led them towards the pursuit of chemistry; so that for want of a companion to quicken my industry, and sharpen my attention, I have made but slender progress in a kind of information to which I have been attached from my childhood. And until your weekly *Journal* appeared, there seemed to be no journal of chemistry whose cost was within my means, and which I could read with profit.

The limestone here is a very pure white or light grey limestone of the carboniferous series; the upper beds are full of corals and other fossils; in some of the lower beds there are bands of chert or flinty rock of extreme hardness. It is a marvel to me how so great a thickness of rock—for the limestone here is upwards of three thousand feet thick—could have been formed in the space of time which my teachers allow for the growth of the world since its creation. From an examination of the rock it appears in its origin to be entirely organic, made up of corals, seaweeds, shells of all kinds, with many smaller organisms. These, while they lived in the slimy ooze, or on the stones at the bottom of some ocean, were able to absorb the carbonate of lime which had been dissolved in the sea water, and they built up from this the delicate shells, stalks, or skeletons which remained after the creatures had ceased to exist.

These broken relics formed in course of ages the stupendous rock I have described, though in the lapse of time there have been many changes. In many places the rock has lost all trace of its original animal origin, and has become like marble, crystalline, with fine crystals of calcite, which glitter after a shower of rain like precious gems.

I see from your pages that there has been some dispute as to what is an organic compound. I do not know whether any dispute will take place as to limestone, but if it does, I beg you to invite the learned referee to spend a night at "The Sportsman's Arms" at Wath, or "The Race Horses" at Kettlewell, and if he will let me know I will gladly escort him to Elbolton or Cracoe Swindon or Coldstones, and will show him such sights that without any further evidence he will agree that the limestone of Craven is organic. But I must admit that my parish is not really in Craven, but only abuts on it; yet I like to consider myself as belonging to Craven, a country above all others where one may get to love the silence that is in the starry sky, the sleep that is among the lonely hills.

On the right hand side of the road that leads to the railway station—for we are quite civilized here though primitive—is a lime-kiln, the use of which goes back to a time whereof the memory of man runneth not to the contrary. Here the limestone is roasted—formerly by a peat fire—but now, since the railway came, by coal; the carbonic acid is driven out from it, leaving only the calcium oxide or lime. Although limestone is so abundant here, the land is constantly in need of lime; the rains wash out the lime from our light soil fairly quickly, and my neighbours are always glad to lime their land; it sweetens the pastures and it kills the grubs and slugs and other vermin, and the farmers tell me that it helps the crops to obtain more benefit from the soil and manure, though I confess I have notenough chemistry to explain how this should be.

The freshly-roasted lime or quicklime is not suitable for the land; it is too hot, and must be slaked by adding one part of water to about three parts of lime. The lime and water unite to make a hydroxide of lime, and the combination gives rise to great heat. Some of the boys in the village last November sprinkled gunpowder on the lime as it was slaking and were much pleased to find it took fire with a considerable blaze.

Lime has a great variety of uses, and one of these is for mortar and cements. In making mortar, the lime is mixed with fine sand and water, and it quickly begins to harden on exposure to air. All air contains a small proportion of carbonic acid, usually about ·04 per cent., and this combines with the hydroxide of calcium to form calcium carbonate and water. The water gradually evaporates, and the calcium carbonate forms a binding round the sand; the sand itself seems to take no part in the chemical change in the setting of mortar.

An ingenious man of my acquaintance formed a company some years ago for the manufacture of artificial stones. He made wooden frames of suitable sizes, packed them with roasted limestone, and then introduced both carbonic acid, which he had recovered from the roasting, and water, and so made an excellent limestone of the exact shape and size he desired; this stone was marbled or grained as he desired and took a good polish. Unfortunately the expense of the roasting and other operations much exceeded the value of the finished stone and the company ended in disaster. This has been impressed on my memory by the fact that my aunt Rachel asked me one day in quite a casual manner if the process was scientifically sound. I told her it undoubtedly was, upon which the foolish woman, without any further advice or consideration, invested twenty pounds of her money in it, and she has often blamed me for the loss of it, which is most unjust. The judicious investment of money is, I imagine, a difficult study. Some time ago a project was started for the recovery of gold from sea-water which indeed does contain a small proportion of this metal in the form, I suppose, of gold chloride. I was attracted by the novelty of the proposal and sent fifty pounds to the promoters and a day or two afterwards I paid a visit to one of my parishioners, Col. B., a manufacturer of ammonia and many other chemicals. He was one of the original members of your Society, was for some years a member of Parliament, and is possessed of great means. Five hundred pounds would be nothing to him as an investment, and I thought he would be easily persuaded to write a cheque for such an amount, but he distinctly objected and on my telling him what I had done he made some remark of which I forget the first part, but I know it ended "are soon parted."

Lead mining has been practised in this parish for several centuries; if tradition is to be believed, the Romans not only mined lead, but smelted it in some parts of Yorkshire. The top of our hill is covered with the debris of old workings, heaps of limestone, mounds of barytes and fluorspar left by the old man, as the primitive worker is known locally. The lead ore occurs as galena or lead sulphide, which is found in a multitude of small veins running through the limestone. The galena is usually accompanied by fluorspar, barytes and calcite and as these are white or colourless crystals and the lead ore is silvery blue or almost black, the appearance of a large block of the vein matter is often very beautiful. A few men are still engaged in exploring the old workings, selling lead ore when the price is favourable, selling barytes at other times, and in the summer months exporting fluorspar to America. Formerly some of the lead ore was smelted here in the smelt mill, but this is no longer in use and the lead ore is now sold to smelters in Newcastle, Chester and Brough. Not that Brough, which the famous George Steadman came from, which is in Westmorland, but another less famous one in Derbyshire. But the water wheel which operated our own smelt mill is still turned round at regular intervals, so that all will be ready for the bold man who wishes to resume smelting here. And winding its way up the hillside for nearly a mile is the stone tunnel or flue to catch the lead fumes and products of combustion from the furnaces in the smelt mill. This flue now provides a home for scores of rabbits and a playground for their young ones; in Nature nothing is wasted. The miners in this parish have handed down their traditions through many generations and they have kept well abreast of modern notions. Some seventy years ago a party of Welshmen settled here with up-to-date ideas of mining and money-making, and a little later some other "foreigners" came into the district, this time from Arkengarthdale, about fifty miles north of this parish, a great place for lead mining. So you see we do not stagnate. The galena, PbS, is roasted and forms sulphate of lead $PbSO_4$; this being heated with more galena the following action takes place:—

$$PbSO_4 + PbS = 2Pb + 2SO_2.$$

Both these actions take place in the same hearth or furnace, and the sulphur dioxide carrying away with it some discoloured lead sulphite, galena and soot, with occasionally a little lead sulphate, finds its way along the flue gradually depositing the solid particles in a fine dust along the sides and bottom of it.

The number of industries in which the lead finds a place is very large. Lead sheets, and lead pipes are much used in building houses and chemical factories; very thin lead sheet or lead foil is used for lining tea-chests and other packages; red lead is used in painting and plumbing; white lead is used in painting; silicate of lead is used very largely in the pottery industry as a glaze. Litharge or lead monoxide, PbO, has many uses; varnish makers use it in making varnishes and driers; the makers of india-rubber use it in making the rubber suitable for motor tyres, and the makers of electric accumulators use it as the chief means of storing electric energy.

Most lead when first smelted contains a little silver and sometimes it contains a minute trace of gold. The lead from our parish is particularly pure, a source of great pride to us, although the lack of the usual few ounces of silver to the ton of lead deprives the miners of a certain amount of profit. Great refinement in metals, as in men, does not invariably tend to the accumulation of wealth.

I intend in a subsequent letter to describe to you the chemistry of our electric accumulators when I deal with the very ingenious way in which we make use of the power of the Stony Grooves beck to furnish electric lighting for our houses.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments of his contributor, but does not necessarily agree with them.

Representatives of Chemical Societies

met last week to prepare their plans for the scientific exhibit which is to be an adjunct to the chemical section of the British Empire Exhibition. I hear that the scheme is to include a propaganda section which will present to the visitor a survey of the outstanding work in chemistry during recent years. A very necessary piece of work, if the scientific visitors are to take away with them some permanent record of what the whole section is intended to show. There is also to be on view selected examples of the research work carried out at our Universities and Colleges, in order that our visitors may be able to see that behind the industry itself there is a stream of invention which flows not less sluggishly in our country than in any other competing countries. So far, so good; but I hear nothing of any provision for meeting my fellow-journalists from abroad or, indeed, of a place where scientific men generally can meet their fellows. Here is a chance for the Chemical Industry Club to show what its members can do!

The Therm Committee

has finished taking evidence, and the last sitting of the Committee was noteworthy for the appearance of Dr. Carpenter in the witness-box. It was a pleasure to hear evidence given by a master in the art. Clear, with the simplicity which comes only with the use of right language; concise, with never an over-statement; his cross-examination merely elucidated further information on additional points which the Committee had in mind. It seemed clear to me from the manner in which the Chairman of the Committee dealt with other witnesses on that day that the Committee had all the information they wanted. Indeed, a less courteous Chairman would not have allowed them to open their lips in the box, for there was much vain repetition. I suppose we shall have to wait some weeks before we get the Committee's Report, but if I were a wagering person I should make a small investment that the system of charging by the therm will remain.

A Warning

The editor has printed some verses which seems to have been suggested by the airy "Meditations of a Sodium Atom" to some youthful reader. I presume he is youthful, though I have no evidence, because one outgrows these and other ailments:—

> "me quoque
> In dulci juventa fervor in celeres iambos
> Misit furentem."

But I think I am performing a friendly action in warning him against allowing this to become a habit. An occasional lapse into verse is excusable, even in scientific people, but it is dangerous; like drug-taking, the taste once acquired, so I am told, may become a malady against which the wretched victim struggles in vain. I should be truly grieved if it were said of our innocent correspondent:—

> "Him too the mania, not the muse has seized;
> Not inspiration but a mind diseased."

On the other hand, if he has already reached years of discretion, I shall feel some anxiety about his future; it seems a small thing to parody a few verses in order to put forward some chemical proposition; but did not a philosopher say: "If once a man indulges himself in murder, very soon he comes to think little of robbing; and from robbing he comes next to drinking and Sabbath-breaking, and from that to incivility and procrastination. Once begin upon this downward path, you never know where you are to stop. Many a man has dated his ruin from some murder or other that perhaps he thought little of at the time." I invite R.T.M.H. to reflect on these observations before he again seeks the assistance of the Muse. It is his moral state which troubles me, not my own reputation, which is above suspicion.

Sir William Alexander's Letter

to the consumers of dyestuffs, containing as it does an assurance that they can rely on British dyestuffs if the difficulties abroad increase, and the crisis is prolonged, should serve to allay any anxiety. It is interesting to see how the consumers turn to the British maker as soon as there is difficulty in obtaining dyestuffs from the Continent. Yet, such is the habit, they still continue to decry British dyes. I heard an interesting example of this only a few days ago in connexion with the forthcoming British Empire Exhibition. It appears that while the agitation for the use of none but Empire products was in full blast the British dyemakers put in a claim that none but British dyes should be used in the Exhibition. The authorities were solemnly told by certain users in the North of England that the British makers could only supply a small percentage of the dyes required! This canard was instantly killed by the production to the authorities of the sample colour books of some of the firms. It is a pity these books are so expensive to produce; they should have a much wider circulation. I very much doubt whether people like Professor Armstrong have ever seen them, judging from his article in last week's issue. They prove conclusively that the range of colours now being made in this country is very much wider than most people suspect. It is not, however, absolutely complete, so the upshot of this matter is that, as far as possible, none but British dyes will be used in the Exhibition.

FORTHCOMING EVENTS

Feb. 9. Society of Chemical Industry, *South Wales Section*, Technical College, Mount Pleasant, Swansea, at 7.15 p.m. "Stainless Steel and its Uses," by H. B. Hitch.

Feb. 9. The Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 9 p.m. "Rothamsted and Agricultural Science," by Sir John Russell.

Feb. 9. Physical Society of London, Imperial College of Science and Technology, South Kensington, S.W., at 5 p.m. Annual General Meeting will be held, after which (1) a paper will be read on "The Eötvös Torsion Balance," by Capt. H. Shaw and E. Lancaster-Jones, and (2) a demonstration of the 'Flame Phone' will be given by H. W. Heath.

Feb. 9. Chemical Engineering Group, The Chemical Industry Club, 2, Whitehall Court, S.W. 1, at 8 p.m. "Some Control Formulæ in connexion with Leaching and Evaporating," by Prof. F. G. Donnan.

Feb. 12. The Biochemical Society, The National Institute for Medical Research, Mount Vernon, Hampstead, at 5.30 p.m. "A Comparison of the Hydrogen-ion Concentration Determined Electrically with the Hydrogen-ion Concentration Calculated from the Carbon Dioxide of Blood in Pathological Conditions," by T. R. Parsons and E. P. Poulton. "The Blood in Polycythæmia," by J. M. H. Campbell, G. H. Hunt, and E. P. Poulton. "The Mode of Action of Vitamins," by W. Cramer.

Feb. 12. The Ceramic Society, Central School of Science and Technology, Stoke-on-Trent, at 7.30 p.m. "Notes on Application of Pyrometers to Ceramic Industries," by Chas. E. Foster.

Feb. 12. Royal Society of Arts, John Street, Adelphi, W.C. 2, at 8 p.m. "The Vulcanisation of Rubber" (Lecture 2), by Henry P. Stevens, M.A., Ph.D.

Feb. 12. The Institute of Brewing, *London Section*, the Institute of Chemistry, 30, Russell Square, W.C. 1, at 8 p.m. "Cellulose Fermentation," by H. Langwell and H. Lloyd Hind.

Feb. 13. Society of Chemical Industry, *Edinburgh and East of Scotland Section*, the Pharmaceutical Society, 36, York Place, Edinburgh, at 7.30 p.m. "Vitamins," by Dr. G. M. Findlay, M.A.

Feb. 13. Institute of Metals. *Scottish Local Section*, Institution of Engineers and Shipbuilders, 38, Elmbank Crescent, Glasgow, at 7.30 p.m. "Some Phases of Lead Manufacture," by John A. Sillars.

Feb. 13. University of London, University College, Gower Street, W.C. 1, at 5.30 p.m. "Electric Fields in Atomic Physics," by Prof. E. T. Whittaker, F.R.S. Also on March 13, 15, 20, and 22.

Feb. 13. Institute of Industrial Administration, London School of Economics, Clare Market, W.C. 2, at 8 p.m. "Practical Hints on Buying and Selling," by F. Mott.

Feb. 14. Royal Society of Arts (Ordinary Meeting), 18, John Street, W.C. 2, at 8 p.m. "Progress in the Manufacture of Refractories," by W. J. Rees, Lecturer on Refractories in the University of Sheffield.

NEWS FROM THE SECTIONS

NOTTINGHAM SECTION

The Meeting held jointly with the Society of Public Analysts on January 17 was devoted to a discussion on "The Detection of Small Quantities of Arsenic." Mr. Burford welcomed the meeting as evidence of the co-operation of chemists from different societies. and stated that an official report of the meeting would be published later. Mr. Chaston Chapman, in opening the discussion, recalled a previous one organised by the Nottingham Section of the Society of Chemical Industry in 1901, and a report of the Joint Committee of that Society and the Society of Public Analysts in February, 1902. He referred to the contamination of beer by arsenic in 1900 and the value of the Reinsch test as a ready method for rough differentiation of contaminated from uncontaminated materials. When it was found that malt itself might occasionally be contaminated, some more delicate method of detection became necessary, and the Joint Committee already mentioned, recommended a modification of the Marsh-Berzelius test, which was very sensitive. Later, attention was turned to the Gutzeit method, which is the standard method of the British Pharmacopœia, and is very useful, especially for "sorting" purposes.

The Marsh test was due to James Marsh, at one time an assistant of Faraday, and afterwards engaged in the Royal Arsenal at Woolwich. It was first published in 1836, and Mr. Marsh was awarded the Gold Medal of the Society of Arts for his communication on it. There is some doubt as to whether Liebig was not the first to recommend the passage of the gas through a heated glass tube so as to obtain the arsenic in the form of a mirror, and Berzelius suggested passing the gas over heated metallic copper so as to convert the arsenic into the silvery copper arsenide. In discussing the details of the Marsh-Berzelius and Gutzeit methods, Mr. Chapman said there was no difficulty in obtaining pure hydrochloric, sulphuric and nitric acids, or cadmium sulphate and cadmium chloride. The calcium chloride used for these tests should be specially purchased and should be in the form of small granules and neutral in reaction. The zinc should not only be pure but must be sensitive.

For the reduction of pentavalent to trivalent arsenic, ferrous or stannous chloride could be used when necessary. Years ago, Dr. Dyer called attention to the insensitiveness of zinc, and experiments by Mr. H. D. Law and himself had shown that this was largely due to the presence of impurities in the metal. By coating insensitive zinc by cadmium it could in many cases be made sensitive, and this method is now widely used. The electrolytic method with a platinum cathode has the disadvantage that the activity of the platinum varies with use.

Mr. J. M. Wilkie alluded to some recently published American papers recommending rod zinc instead of granulated zinc. He alluded to the use of lead instead of platinum as electrodes as suggested by Sand and Hackford. His own method was a combination of Sand and Hackford's apparatus with that of Sir Edward Thorpe, but using a more opaque porous pot, and it included the Gutzeit modification worked out by Hibbert. The use of stannous chloride with ferric chloride seemed to be growing, especially in America. Small quantities of potassium iodide were excellent as reducers. Glycerol reduced arsenic rapidly in solution, but using this with iodide it was necessary to find an absorber of the iodine in acid solution. Terpin hydrate was first tried, but it was subsequently found that glycerol which had been oxidised with permanganate acted similarly to terpin hydrate and had the advantage of being soluble in water. One c.c. of 80 per cent. glycerol is mixed with a tenth of its volume of 50 per cent. sulphuric acid and to the mixture 2 c.c. of 5 per cent. potassium permanganate is added; when colourless the reagent is ready for use. With this reagent the hydrogen iodide is maintained at its original concentration.

Dr. Monier-Williams advocated the electrolytic method. In his own apparatus, the porous pot was very thin and the anode was a strip of lead foil. The cathode was a small disk of lead foil. He had experimented on cooling the tube immediately after the heated part by wrapping round the tube a piece of filter paper with an end hanging down and dipping into water. He found that this procedure gave a sharp ring, and was of advantage in very delicate tests.

Major Trotman, speaking from 30 years' experience as a Public Analyst, said he had had more trouble from the arsenic test than anything else.

Dr. Thorne had found arsenic in malt in quite appreciable quantities. This often gave rise to beer having a percentage above the legal limit. He had tried the electrolytic method, the Gutzeit method and others, but finally returned to the Marsh test, because using 20 grams of material he could determine arsenic representing about 1/1000 mg. He had not always been successful with the method of making zinc sensitive mentioned by Mr. Chapman. He found hydrochloric acid always contained arsenic and he got rid of the arsenic by heating the acid with a copper-zinc couple. He confirmed the benefit of cooling the tube as practised by Dr. Monier-Williams.

Mr. H. Droop Richmond thought the insensitiveness of zinc was largely due to the presence of iron.

Mr. Webster preferred the electrolytic Marsh method. Using platinum, he considered the limit of sensitiveness at 1/500 mg. Platinum electrodes became less sensitive in time, and it was necessary to polish them occasionally and sometimes to reverse the current.

Mr. Jenson said his experience of the electrolytic process showed it was very successful, the limits of sensitiveness being about 1/1000 mg.

Mr. Ellis Richards expressed his satisfaction at the Joint Meeting.

Dr. Dyer said pure zinc was very slowly attacked by acids and it was useful to alloy it with 0·1—0·2 per cent. of pure electrolytic copper and then to coat this insensitive metal with cadmium. He did not purify hydrochloric acid, but bought it specially pure.

Mr. Weaver and Mr. Bolton also took part in the discussion.

MANCHESTER SECTION

A meeting was held on February 2, Dr. E. Ardern in the chair. Members of the Manchester Geographical and Mining Society, the Manchester Section of the Institute of Mechanical Engineers, and the Manchester Association of Gas Engineers, attended by invitation, and about ninety persons were present.

A paper, entitled "A New Process for the Manufacture of Sodium Thiosulphate," by Mr. Luke Hargreaves and Dr. A. C. Dunningham, was read by the latter. Before the war, practically all the sodium thiosulphate manufactured in this country was prepared from Le Blanc waste, which contains a large percentage of calcium sulphide. On exposing this waste to air for oxidation considerable quantities are formed of calcium thiosulphate, which is extracted and treated with sodium carbonate or sodium sulphate to precipitate the insoluble lime salt; the sodium thiosulphate left in solution is crystallised out. Since the Le Blanc process has been definitely superseded by electrolytic methods, the exhaustion of the raw material is only a question of time, whilst the heavy cost of the labour and fuel necessary now militate very seriously against the process.

To prepare sodium thiosulphate directly sodium sulphite and sulphur are caused to react, according to the equation $Na_2SO_3+S=Na_2S_2O_3$. This reaction is well-known, but the conditions for carrying it out on a commercial scale have, apparently, never been worked out before. If sodium sulphite and sulphur are agitated with water in the correct proportions to form a concentrated solution of thiosulphate, the rate of reaction decreases with increase of thiosulphate concentration, owing to the reduced reacting contact between the sulphur and sulphite. The most effective way of increasing this contact is to use a large excess of one or both of the solid reacting substances. By this means solutions of thiosulphate of sufficient strength to crystallise without concentration can be prepared directly. All the ordinary impurities are only slightly soluble in concentrated thiosulphate solutions, so that after filtering or settling such solutions are of great purity. A commercial process was described for preparing thiosulphate in this way, and also a further development, in which sodium carbonate, sulphur dioxide, and sulphur in the presence of water react simultaneously to produce a similar concentrated solution of thiosulphate.

Dr. A. C. Dunningham also read a paper on "The Factors Determining the Choice of Materials for Stone Dusting of Mines, with Special Reference to Carbonate of Lime." Under the Coal Mines Act the stone-dusting of coal mines has been made obligatory, the only alternative allowed being treatment with water. The efficiency of a stone dusting-material depends upon its capacity to absorb heat rapidly, so that the mixture of dust and coal does not reach a sufficiently high temperature for explosive combination to take place. The physical properties of stone dusting-material are most important, since the rate of absorption of heat depends mainly upon them. An amorphous and finely-divided material with a large surface in relation to mass, *e.g.*, precipitated carbonate of lime, is particularly good from this point of view. A stone dusting-material should therefore: (1) be incombustible; (2) be very finely divided; (3) possess a large surface relative to mass, and its structure should preferably be amorphous and porous; (4) be dry; (5) easily form a cloud when disturbed; (6) be harmless to health; (7) be uniform in composition in order to simplify proper control over the stone dusting process; and (8) it should be white or very light in colour, so as to lighten the mine. Precipitated carbonate of lime approximates most nearly to the ideal substance for stone dusting, owing to its efficiency in use, and economy of production, due to the elimination of an expensive grinding process.

Shales, on the other hand, vary greatly in composition and properties (thus necessitating chemical control), but have the advantage of being obtainable at the mine. Grinding, however, is costly and this is often realised only after a period of working long enough to show the full extent of the wear and tear on the plant; further, the degree of fineness obtained does not often approach that of precipitated carbonate of lime. The effect of any shale upon the miner's health is a matter for experience, besides being uncertain owing to its varying composition. Precipitated carbonate of lime is free from all these disadvantages, and in the future it will probably largely replace shale as a material for the stone dusting of mines.

The third paper, on "Some Developments in Gas Producers," was by Mr. T. Roland Wollaston, M.I.Mech.E. The ammonia-recovery gas producer of ten years ago was said to be capable of (1) giving gas of 160 B.Th.U. higher value; (2) working at 70 per cent. thermal efficiency; (3) running upon a wide range of bituminous slacks with high ash and moisture contents; and of (4) yielding about 70 lb. of sulphate of ammonia per ton of coal per 1 per cent. nitrogen in the coal fed to producers. Undoubtedly, such results were sometimes obtained, and then only under special conditions of upkeep and skilled attention. The average gas produced did not exceed 130 B.Th.U. higher value, nor the thermal efficiency 60 per cent. The range of fuels which could be worked was distinctly limited in chemical composition, physical structure and condition, and the gas produced largely depended on hydrogen for its thermal value, a feature unattractive for many industrial applications. Of the total fuel consumed a considerable proportion generally went in raising the large amount of steam required (over 2 of steam to 1 of coal by weight), and yielded no by-products. The removal of ash in large plants using low-grade fuels was a very formidable problem, and the tar obtained was of low value. There seemed to be three axioms:—

1. Coke is always a good producer fuel. There is enough heat in the gas leaving a producer to coke, or at least semi-coke, the incoming fuel. If this coking is obtained by direct contact between gas and fuel the more volatile constituents of the latter will be taken up by and enrich the former. The final issuing gas will be cooled down considerably. Coke or semi-coke only will reach the producer.

2. High blast saturation in early recovery producers was adopted for physical rather than chemical reasons—*i.e.*, to reduce the temperature of the combustion zones, to avoid decomposition of ammonia, and to prevent the formation of clinker. Such moderation of temperature should be obtainable as well by useful radiation as by direct contact. The heat thus radiated is sufficient to raise all the steam necessary.

3. The water-bottom type of producer is at once best and cheapest. Mechanical and controllable discharge of ash is sound and economical.

A detailed description of a new plant fulfilling all the above requirements was then given.

Pre-coking leads to wide extension of the range of common fuels available, to practical elimination of clinkering, to great ease and economy of working, and to the production of a gas of unusually high value as for example:—Saturation, 74° C.; CO_2, 10·6%; O_2, 0; CO, 18·8%; H_2, 24·4%; CH_4, 3·9%; Total combustible, 45·1%; higher C. V., 182·5; lower C. V. 164·5.

Engineering problems have now been so far surmounted that continuous tests over long periods can be organised and it will soon be possible to present detailed records demonstrating clearly that the recovery gas producer must play an important part in industry.

In some supplementary notes Mr. Booth pointed out that the high value of the gas obtained extends the field for use of producer gas very considerably and the range of possible fuels almost indefinitely. He adduced evidence to show that the yield of by-products, ammonia and tar will be superior to those hitherto obtained and that still higher efficiencies will be obtained.

GLASGOW SECTION

The sixth meeting of the session was held in the Institute of Engineers and Shipbuilders, Glasgow, on February 2, Mr. W. E. Moodie presiding.

The meeting was arranged in accordance with the scheme whereby Fellows of the Chemical Society might give brief accounts of papers to be published in the Transactions of that Society, or raise points of general or theoretical interest to members of the local sections. The chairman intimated that the Committee had decided to offer a prize for the best original thesis presented by a Student Associate of the Section.

The following papers were read and discussed :—

(1) "Double Salts," by Mr. J. Ferguson, B.Sc. An account was given of researches on the dissociation pressures of double salts. Those investigated had been the hydrated double sulphates of the type $RSO_4, M_2SO_4. 6H_2O$. In the series where "R" was copper and "M" was one of the alkali metals it was found that the affinity or "free energy" at 50° C. increased in the order potassium, rubidium, ammonium and caesium, whilst the dissociation pressures decreased. In the course of the investigation the double dihydrates of copper and rubidium, ammonium and caesium had been prepared for the first time, and it had been proved that the vapour pressures of the hydrated salts depended on the electrochemical properties of the metals.

(2) "The Strength of Ammonia as a Base," by Prof. R. M. Caven, D.Sc. In this communication, theoretical conclusions were drawn from the results of the investigation reported in the previous paper. Attention was directed to the fact that ammonium salts stood high in the series of the alkali metals, whereas ammonium hydroxide was a weak base.

It was shown that there was no necessity to assume first the existence of the compound, ammonium hydroxide, and its subsequent dissociation in solution.

(3) "Some Comparative Experiments on the Dyeing Properties of Lichens," by Prof. T. S. Patterson, D.Sc. Experiments were described that were conducted during the war—and for the Board of Agriculture for Scotland—to discover natural dyestuffs. The tests were comparative and consisted of boiling flannel with similar quantities of various lichens, water and concentrated ammonium hydroxide. In many cases the flannel did not dye evenly and many of the colours were unsatisfactory. Amongst these were the various "crattles." It was concluded that many natural substances have tinctorial properties and that "the colouring matter" could be extracted with a solvent such as alcohol. The quantities of "raw material" available, however, varied greatly.

(4) "The Estimation of Inorganic Impurities in Organic Compounds Soluble with Difficulty in Water ; as Sulphuric Acid in Picric Acid," by Prof. T. S. Patterson and Mr. K. L. Moudgill, B.A., B.Sc. The method consists in bubbling steam through picric acid contained in a flask immersed in a boiling solution of concentrated sodium carbonate at 130° C. The aqueous layer which formed was filtered off and tested for sulphuric acid.

LONDON SECTION

Mr. W. J. U. Woolcock presided at the meeting of the London Section at the Engineers' Club, on February 5.

The first paper was entitled "Explosions in Liquid-Air Plants," by Dr. E. Fyleman. This paper, which appeared in full in our issue for January 26, p. 37 T, described investigations which led to the conclusion that the explosions were caused by acetylene produced by oxidation of the oil used to lubricate valves and other parts of the compressors.

Dr. W. R. Ormandy said the paper obviously bore upon the mysterious explosions which occurred at times in the air compressors used with Diesel engines, in which air at a pressure of from 1000 to 1200 lb. per sq. in. was sent into the cylinder. The danger of explosion had been reduced by using steel coils instead of copper coils to bring the air from the compressor to the engine, and that suggested that acetylene had something to do with it, since acetylene would form an explosive acetylide with copper. It would be extremely interesting to investigate the relationship between temperature and pressure of air under which lubricating oils formed acetylene or di-acetylene bodies. The question was also of interest in relation to internal-combustion engines in which very high temperatures and fairly high pressures occurred during the compression stroke.

Mr. Napier Prentice (Past-President of the Diesel Engine Users' Association) said the matter was of interest to Diesel engine users, because the deleterious material which formed in the compressors and led to explosions was really wanted in the cylinder of the engines. If the pressure and the temperature at which acetylene was formed could be ascertained, it foreshadowed a most important development in regard to internal-combustion engines, and especially those for aeroplanes, as possibly a fuel could be used at a lower ignition temperature.

Dr. Symons referred to explosions due to compressed-air plants where it was subsequently found the lubricating oil was to blame, inasmuch as at high temperatures it formed a gaseous mixture with oxygen or highly compressed air.

Dr. J. A. Harker, F.R.S., emphasised the importance of keeping a liquid-air plant well away from any place where acetylene was being used. The difficulty was encountered during the war at plants for fixation of nitrogen for munitions. These were on the site of a big carbide works in order to make cyanamide, and there was also a liquid-air plant to separate the nitrogen from the air. At the largest cyanamide plant in the world, Muscle Shoals, in the United States, very great precautions were taken to keep acetylene away from the liquid-air plant. A large conduit half a mile north and another half a mile south of the works were constructed so that they could take air in to the liquid-air plant uncontaminated by the acetylene produced at the cyanamide factory. In many works in Switzerland, Italy and Norway the same trouble had been experienced, but they did not take such elaborate precautions as had been taken in America, and seemed to hope that the acetylene would not get into the liquid-air plant.

The discussion was continued by Dr. Thorne, Mr. Horner, and Dr. Dvorkowitch.

Dr. Fyleman, replying to the discussion, said that even if a long conduit were used for the air inlet to the liquid-air plant, great care had to be taken to avoid leakages. The difficulty in the oxygen industry was quite different from that which he had referred to. Even if there were only traces of acetylene, that would collect in the solid state in the oxygen. The reason why liquid oxygen exploded so violently was that its latent heat of evaporation was only 50, so that the total heat of combustion of the carbon or, worse still, the acetylene, was diminished by this quite small amount of latent heat, and the results were really startling.

A paper by Messrs. G. T. Bray and F. Major on "The Estimation of Fat in Casein" concluded the meeting.

MEETINGS OF OTHER SOCIETIES

INSTITUTE OF CHEMISTRY

At a meeting of the Huddersfield Section held on January 24, Dr. A. E. Everest gave a lecture on "Plant Pigments."

The chairman, Dr. Hodgson, in his opening remarks, referred to the pioneer work in the exact science of these pigments carried out by the lecturer in collaboration with the German chemist, Willstätter.

Dr. Everest said that the industrial application of these pigments was small and was likely to become smaller. Nevertheless, he thought it was sometimes a good thing to turn to subjects of only scientific interest. Plant pigments could be divided into groups—viz., chlorophyll, the insoluble pigments, and the sap pigments; indigo and madder were quoted as isolated examples of colouring matter. As he had worked mostly with the sap pigments, he proposed to give a short account of the stages in the elucidation of the chemical constitution of these bodies. He clearly explained the connexion between the flavones, the flavonols and the anthocyanins, and described his own contributions to the chemistry of this subject. The initial difficulties of the investigation of the blue colouring matter of the cornflower were indicated. Several hundredweights of dry cornflower petals were required to give sufficient material to work upon, the petals had to be taken from flowers recently opened, and the actual extraction had to be carried out very rapidly in order to avoid decomposition. With one or two exceptions, all these pigments were attached to some sugar as a glucoside. With regard to the tinctorial value, a variety of pleasing shades could be obtained from a cold bath on tannined cotton, which are fast to light and dry-cleaning, but fugitive to hot water and alkali. The lecture concluded with the exhibition of specimens of historical interest and of dyeings from radish skins, pelargonium petals, blackberries, etc.

SOCIETY OF DYERS AND COLOURISTS

Two papers were read at the meeting of the Manchester Section held on January 19. In the first, on "The Behaviour of Titanic Acid towards Dyestuffs," by Dr. J. K. Wood and Mr. A. M. Morley, the alpha and beta modifications of titanic hydroxide were discussed, and it was suggested that the alpha acid exists in the form of small particles more readily attacked by reagents than the larger and more complex particles of beta acid. If this is true, the possibility arises of the existence of several modifications of the acids, a hypothesis which is in agreement with the behaviour of oxides of related metals. There will thus be a continuous series of titanium hydroxides gradually increasing in beta character as condensation occurs, owing to the titanium hydroxide functioning in two capacities. The result of this will be the gradual decrease in surface area of the particles. Therefore a sample of titanic acid having a pronounced beta character will possess a smaller absorptive capacity than one in which condensation is less advanced.

Prof. E. Knecht and Mr. G. H. Street presented a paper, entitled "Investigations on the Constituents of Raw Cotton, Part 4," which was devoted to an account of investigations on cotton wax. It was concluded that extraction of the raw cotton with benzene removed about half of the wax, whereas if the fibre is destroyed by chemical or mechanical means the whole of the wax can be extracted, the content being just over 1 per cent. The wax was found to contain what appeared to be another definite compound, differing in solubility, melting point and composition from that described by Schunck.

THE CHEMICAL SOCIETY

Three papers were read at the meeting of the Society on February 1, presided over by Sir William Tilden :—

The first paper, on " Derivatives of Tetrahydrocarbazole Part II.," was by W. H. Perkin and S. G. P. Plant. The latter author gave an account of some of the chemical reactions of tetrahydrocarbazole associated with its peculiar linking. The behaviour on nitration is unusual. Nitration with a mixture of sulphuric and nitric acids led to the nitro group entering para to the NH group ; if, however, the acetyl compound was nitrated the nitro group entered meta to the NH group, the reverse of the usual orientation. Further work was described dealing with addition at the double bond of the partially reduced ring and a new type of nitro compound was evidenced. The results were found to conform to the Lapworth-Robinson hypothesis. In the discussion, Dr. Brady referred to the failure of ring closure when nitro groups are present in certain common synthetic methods for the preparation of carbazole derivatives. It seemed that the unusual behaviour on nitration indicated an abnormal polarity of the remaining carbon atoms which might afford a possible explanation.

In view of the recent communication to *Nature* of January 20, by Professors Coster and Hevesy, working at Copenhagen, of the identification by its X-ray spectrum of a new element which they have named Hafnium and probably has the vacant atomic number 72 (to which place the problematical element Keltium had been earlier assigned), the communication of Dr. Scott was of peculiar interest. He actually showed a sample of the oxide of the new element which was isolated from a sample of black iron sand from New Zealand. The sand is titaniferous, not a monazite, and exhibits none of the properties of the rare earths. It was decomposed by treatment with strong sulphuric acid, and a residue was obtained which was freed from titanium sulphate by repeated extraction with sulphuric acid. It was then fused with sodium bisulphate, and the melt after solution still left a notable quantity of white residue which was fused in a gold crucible with caustic soda and the residue after solution once more put through this process. This final residue, a pale, buff-coloured powder, is presumably the oxide of a new element belonging to the titanium—zirconium group. It further shows the properties of this group, as it was found impossible to form a nitrate, chloride, etc. It does, however, give rise to a double fluoride when treated with hydrogen potassium fluoride. On converting this double salt again into oxide by heating with sulphuric acid and washing out the potassium sulphate formed, data were obtained which allowed the atomic weight to be calculated as 175.

The oxide still, however, shows coloration, which may be due to minute traces of iron. Dr. Scott first isolated the oxide in 1915, 1·4 g. of the substance being obtained. He has only just, however, made the determination of the atomic weight of the metal. Using quartz weights and pure hydrofluoric acid, he hopes to make a more accurate determination of its atomic weight. He has also offered to send a sample of the oxide to Denmark for a comparison to be made by the X-ray spectrograph with Hafnium. Future treatment of the original sand may be made with hydrochloric instead of sulphuric acid, as the former decomposes the iron, leaving a cream-coloured sand residue. There is stated to be a belt of the sand 70 miles in extent on the New Zealand coast, so that ample material will be available for future investigation.

In congratulating Dr. Scott on his discovery, Sir W. Tilden said that it was a notable event, and the Society was also to be congratulated, as few such discoveries had been communicated to it. Prof. H. E. Armstrong expressed his appreciation of the discovery and observed that Dr. Scott was well known as a very exact worker. Attempts to name the element were premature, as the element itself had not been isolated. The new element should be named after Moseley, as Moseley's work had made the discovery possible. Congratulations from chemists outside the London area were voiced by Prof. Smithells, who gave instances of the almost simultaneous discovery of other elements by independent workers.

The last paper, by C. K. Ingold, E. A. Seeley and J. F. Thorpe, was entitled " The Chemistry of Polycyclic Structures in Relation to their Homocyclic Unsaturated Isomerides. Part IV. The Simulation of Benzenoid Properties by the Five-carbon Intra-annular Nucleus."

CORRESPONDENCE

Sir,—How delightful it is to find an original member of the Society of Chemical Industry who can laugh. The laugh is not echoed by the unfortunate representatives of the chemical industry who have expended perhaps a hundred thousand pounds of their shareholders' money in obtaining a legal interpretation—save the mark—of a litigation-inviting schedule appended to a simply expressed Act of Parliament.

Truly, there is but one chemistry. Unfortunately, however, we cannot now produce men who can embrace the whole of " natural philosophy," but have had to separate chemistry from physics and even to subdivide these two quite arbitrarily defined fields of knowledge.

Indeed, Mr. Joseph Barnes himself saw that omniscience could not outlast his younger days; so he talked glibly of "organic" carbon, of "organic" matter and of "organic" substances (J., 1886, **15**, 82; 1898, **17**, 430; 1908, **27**, 212).

Many people sympathise with Mr. Barnes' protest against the intrusion of such novelties as phase rules, ions, isotopes, etc., and share his resentment at the idea that chemistry has progressed since Wöhler's day. But the chemist who fails to realise that science advances, and that electrons, isotopes and the like novelties are living things, will be more at home in the lethal chamber than in the strangers' gallery.—I am, sir, etc., WILLIAM J. POPE

University of Cambridge.
Feb. 5, 1923.

THE FEDERAL COUNCIL

Sir,—I am overjoyed to see from the contents of the first few issues of CHEMISTRY AND INDUSTRY that consideration is now being paid, not only to the taste of the more inconspicuous members of the Society, but also to the more humane aspects of our common profession. The *Journal* seems rejuvenated. I note "editorials" urging us to unite, space is even found for the views of distinguished advocates, and plain men can now actually see themselves in print. All this promises most highly for the future and, stimulated by the new atmosphere, I am impelled to ask for enlightenment, as many of us are not too well informed about the activities of those who control our corporate destinies. In the issue of January 26, p. 76, "One of the Three" writes that the Federal Council should make some real effort to materialise the dreams of a central palace of chemistry. With such dreams every chemist will eagerly sympathise, but may we know by what magic the Federal Council, Aladdin-like, will bring about this "materialisation"? Is it not high time that something more concrete than dreams was put before us?—I am, Sir, etc., P. M. J.

Manchester,
February 3.

PERSONALIA

Prof. A. Miethe has resigned the editorship, which he has held for 30 years, of *Das Atelier des Photographen*, and has been succeeded by his colleague, Prof. O. Mente.

Prof. W. Friedrich, director of the Radiological Institute of Freiburg University, has been appointed director of the newly-founded Institute for Radiotherapy, in the University of Berlin.

Dr. E. K. Rideal has been co-opted as an additional member of the Degree Committee of the Special Board for Physics and Chemistry of the University of Cambridge.

Mr. A. W. Nash has been appointed Senior Lecturer in Petroleum Technology in the University of Birmingham, and Dr. E. E. Turner has been appointed demonstrator in the Chemical Department of the East London College.

The Hon. Charles E. Pellew, who now enters the peerage, owing to the death of Lord Exmouth, is a member of this Society, and was formerly professor of chemistry at Columbia University, U.S.A.

Messrs. J. W. Hawley and J. King have passed the examination for the Fellowship of the Institute of Chemistry, and Messrs. G. W. Bender, A. P. Cattle, J. Lomax, F. C. Madden, J. B. McKean, C. J. Powell, T. E. S. Reynolds, T. W. Dallimore, W. Smith, M. H. Hansford, V. T. Tadman and G. Taylor have passed the examination for the Associateship.

Dr. Thomas B. Downey is the present incumbent of the industrial fellowship in the Mellon Institute of Industrial Research of the University of Pittsburg, established by the Edible Gelatine Manufacturers of America, Inc., for the purpose of ascertaining the real food value of edible gelatin. In addition to experimental investigations, a correlation of available facts regarding edible gelatin will be made, to be held at the disposal of all users.

Dr. Charles D. Walcott, secretary of the Smithsonian Institute, president of the National Academy of Sciences, and formerly director of the United States Geological Survey, has been elected president of the American Association for the Advancement of Science; Dr. Morris S. Kharasch has been appointed associate professor of organic chemistry at the University of Maryland; and Dr. Richard C. Lord has been elected assistant professor of chemistry and physics at Kenyon College, Gambier, Ohio.

* * *

From Prague the death is announced of Prof. Karl Wrba, president of the Czech Academy of Sciences.

The death is announced of Dr. J. Waddell, Professor of Analytical Chemistry, Queen's University, Montreal, and one of the founders of the Canadian Institute of Chemistry.

From Germany the death is announced, at the age of sixty-three, of Prof. Paul Jacobson, who was for many years general secretary of the German Chemical Society, and had rendered notable services in organising the production of that Society's publications, particularly *Beilstein*. Jacobson was co-author, with Victor Meyer and other workers, of a large treatise on organic chemistry, and had published numerous papers on mercaptans, azo compounds and similar subjects.

ERRATUM.—Under the heading of "Deaths" in the issue for January 26, the address of the late Mr. A. L. Crosfield should have been given as Birkenhead, not Berwickshire.

NEWS AND NOTES

UNITED STATES

A New Chemical Society

The American Institute of Chemistry was organised at a meeting of New York chemists on January 22. This new society will include only chemically trained men who qualify for membership by education and experience. It will act on the same lines as the Institute of Chemistry of Great Britain and the Canadian Institute of Chemistry, which have been successful in giving to the vocation of chemistry a professional status by recognising as entitled to be called chemists only those who satisfy certain standards of capacity. Dr. H. G. Byers, department of chemistry, Cooper Union, and Dr. Lloyd Van Doren, a chemical patent lawyer, are respectively president and vice-president, C. K. Simon, president, Dye Products and Chemical Co., New York, is treasurer, and the secretary is Lloyd Lamborn, editor of *Chemical Age*.

Output of Petroleum in 1922

It is reported that the production of crude petroleum in the United States in 1922 was 550,000,000 barrels, the largest amount ever reported, and an increase of 17 per cent. over the production in 1921. A recent estimate suggests that the output in 1923 will be still larger, but consumption in the United States and elsewhere is increasing steadily, and the shortage of production and transportation of Mexican oils, coupled with the fact that no new fields of any importance are being discovered abroad, makes the situation serious. The percentage of the world production attributed to the United States in 1922 was 66·5, compared with 21·7 for Mexico and 11·8 for the rest of the world.

The production of gasoline was 5,810,000,000 gallons, an increase of 700,000,000 gallons over the figures for 1921. It is estimated that in 1923 over 6,000,000,000 gallons of gasoline, *i.e.*, the production from 600,000,000 barrels of crude oil, will be needed to meet requirements. It is estimated that the United States will be forced to enter foreign fields on a larger scale to ensure supplies of petroleum and its distillates for its own needs.—(*Oil, Paint and Drug Rep., Jan.* 15, 1923.)

CANADA

Production of Iron and Steel in Canada

A report issued by the Dominion Bureau of Statistics states that the production of pig iron during December was 4·7 per cent. above the record of the previous month, the tonnages being 34,289 long tons in November and 35,891 t. in December, 1922. The average monthly production throughout the year was 31,921 t. The total production of pig iron in 1922 was 383,057 t. as compared with an output of 594,354 t. in the previous year. The production of ferro-alloys was well maintained, the output for December being 2246 t. and the total output was 20,749 t. as compared with 22,493 t. in 1921. The number of blast furnaces in operation remained unchanged during December: two at Sydney, one at Hamilton, and one at Sault Ste. Marie. Steel production during 1922 totalled 485,643 t. while 667,484 t. was produced in 1921. The total steel production for the six months ending June 30, 1922, was 177,080 t. whilst 308,140 t. were produced during the last half of the year.

SOUTH AFRICA

The New Coal By-product Plant

The new coal by-product plant of the Dundee Coal Co. at Waschbank (Natal), which cost over £300,000, has begun operations. The plant will produce coke, tar, benzol, sulphate of ammonia, naphthalene, creosote and varnishes, and eventually aniline dyes and other commodities. The annual capacity of the plant is 49,795 tons of metallurgical coke, 412,000 gallons of tar, and 655 tons of sulphate of ammonia. Later on the factory will also produce 98,280 gallons of benzol per annum.—(*S. African J. Ind., Jan.*, 1923.)

BRITISH INDIA

First Forecast of the Winter Oilseeds Crop

Estimates based on reports received from provinces containing 98·7 per cent. of the total area under rape and mustard and 99·2 per cent. of the total area under linseed in British India indicate that the acreage (excluding the mixed crops of the United Provinces) under rape and mustard totals 3,621,000 and under linseed 2,290,000. These figures represent increases of 10 and 14 per cent., respectively, above the areas estimated at the same time last year. The present conditions of the crops are reported to be good.—(*Ind. Tr. J., Jan.* 11, 1923.)

GENERAL

Educational Work of the Paint, Varnish and Colour Industry

Prior to the outbreak of war an appeal was made for subscriptions to a fund to endow a scholarship for students in the Paint, Oil, and Colour Department of the Borough Polytechnic Institute, London. This appeal, which had to be abandoned during the war, has been renewed, and to date £113 has been received. The subscription list remains open until March 31, 1923, by which date it is hoped that a total of £200 will be realised. It is intended to hand over to the Governors of the Institute all monies received, for investment in trustee stock, the income from which is to be awarded annually as the " Trade (1923) Scholarship in Paint Technology." In awarding the scholarship, equal if not greater importance will be attached to the record of the work of the pupil during the year than to the results of answering a single test paper at the end of the session.

The vital need for encouragement of study on proper lines in these industries is keenly felt, and to that end an Advisory Committee of Trade Experts was formed some three years ago. The Committee not only acts in an advisory capacity, but conducts the internal examinations of the Institute in the department concerned—a system which might with advantage be applied in many other teaching institutions. It is felt that the successful work which has been carried on in the past in the Paint, Oil and Colour Department of the Borough Polytechnic should be extended, and manufacturers and old students who have not subscribed to the 1923 Scholarship Fund are invited to send their subscriptions to the Hon. Secretary, Mr. Noel Heaton, 1, Hilly Fields Crescent, Brockley, London, S.E.

REPORT

REPORT OF THE MEDICAL RESEARCH COUNCIL FOR THE YEAR 1921-1922. *Pp.* 125. *H.M. Stationery Office*, 1922. *Price* 3*s.* 6*d. net.*

This, the eighth annual report of the Medical Research Council (formerly Committee) appointed under the National Health Insurance Act, is divided into five sections, dealing with:—I, the work of the National Institute for Medical Research, Hampstead; II, the research work of clinical units; III, the determination of biological standards and the methods of biological assay and measurement; IV, research work on specific subjects; V, industrial medicine and industrial fatigue. It covers the period October 1, 1921, to September 30, 1922. For this purpose a grant-in-aid of £130,000, a modest sum withal, was provided by Parliament, the distribution being effected as follows:—£34,000 for the expenses of the National Institute for Medical Research, Hampstead, £88,000 for research grants to scientific men and for the expenses of the scientific researches in specific subjects, for research work in clinical medicine, and for the work of the Industrial Fatigue Research Board, and £8000 for administration expenses.

A perusal of the report shows that the scope of inquiry is not that embraced by a narrow interpretation of medicine, but by the whole field of medical research covered by the broad-minded conception of medicine as defined in the report itself —" The conception of medicine is concerned not only with the palliation and removal of disorder and pain, but with the prevention of disease, with the maintenance of health no less than with its restoration, and with the choice of conditions in which the body machinery of mankind can develop most harmoniously its fullest powers." No chemist can quarrel with this definition nor with the report itself, representing as it does a stage and only a stage, both of the peaceful penetration of the chemist and of chemistry into a domain where chemistry must be the handmaid of medicine, and of the tardy recognition by the medical sciences of the indissoluble bond linking chemistry and medicine.

Some of the subjects of special interest to chemists may now be briefly noted. On the subject of biological standards, Great Britain lags behind the other great nations. Progress is, however, rapidly being made to remedy this defect, and there is every reason to believe that with the talent available the biological standards and methods of assay will be superior to those of any other country. As a result of work done at the National Institute for Medical Research by Drs. Dale and Burn, by Miss Durham and Miss Marchal on the curative action of Neosalvarsans prepared by British manufacturers on experimental trypanosome infections in mice and of the parallel observations of Major White and Mr. Mills at the Military Hospital, Rochester Row, on the curative effects in human syphilis, Neosalvarsans are now made by British manufacturers of the highest possible therapeutic efficiency. Drs. Dale and Burn have also shown how pituitary extract may be standardised so that obstetricians are guaranteed a uniform product. These workers found an 800 per cent. variation in activity in the products from the five firms who supply it in this country. British standards for diphtheria and tetanus antitoxin are being prepared by Dr. Hartley, and the first serum standard for Britain is promised shortly. The National Collection of Type-Cultures under the curatorship of Dr. St. John Brooks at the Lister Institute is steadily being enlarged, and the Standards Laboratory of Oxford under Professor Dreyer supplies standardised agglutinable cultures and agglutinating sera to approved applicants.

In the field of biochemistry and pharmacology there is much solid progress. The problem of the isolation of the pituitary principle to which Dr. Dudley has devoted so much attention appears insoluble by present means and methods. This principle is undoubtedly one of the most active substances known; a crystalline picrate was isolated, which, after several crystallisations, had an action on uterine muscle equivalent to that of the intensely active substance histamine, and yet this picrate was an inert substance, potassium creatinine picrate, with a trace of the true active principle adherent. Sir T. Lewis and his colleagues have established the value of the cinchona alkaloids, particularly quinidine and hydroquinidine, in the amelioration of auricular fibrillation, and parallel clinical observations have been made by Drs. Clark-Kennedy and Ellis. Dr. King has contributed to the fundamental stereoisomerism of the cinchona alkaloids, and, in addition, has isolated the alkaloid muscarine, the poisonous constituent of the Common Fly Agaric. Every medical student is familiar with the effect of this intensely active poison on the frog's heart, but contrary to previous conceptions Dr. King finds no evidence for a relationship with choline. An adequate supply of *Amanita muscaria* is, however, required before the build of the muscarine molecule conferring its intense localisation in the living tissues can be visualised. Professors Browning and Cohen and their co-workers are continuing their co-operation in the investigation of antiseptics, and the group of photographic sensitisers represented by the cyanine dyes have been found to be highly bacteriostatic.

The vitamins and problems of nutrition find many devoted workers. The beneficial effects of cod-liver oil find an explanation in the observation of Professor Drummond and Dr. Silva that the poorest samples are many times richer in vitamin A than average samples of butter. Many workers have contributed to the problem of rickets, and the present conclusion is that absence of the anti-rachitic vitamin is probably the most important factor in the causation of rickets in winter, and sunshine may be the chief preventive factor in summer. A vitamin appears essential for the growth of pathogenic bacteria *in vitro*. Dr. Laidlaw is concerned with this problem and its important applications in media for bacteria. Experiments are in progress with a view to isolating this constituent.

This list might be indefinitely extended, as the major portion of the report deals with purely medical subjects; but sufficient has been said to show that whatever arguments may be adduced against State-aided research, the work guided by the Medical Research Council is of inestimable and lasting benefit not only to the British Empire but to the world at large.

REVIEWS

The Theory of Allotropy. *By* Prof. A. Smits. *Translated by Dr. J. Smeath Thomas. Pp.* 397. *London: Longmans, Green & Co.,* 1922. *Price* 21*s. net.*

This volume forms one of the well-known Text Books of Physical Chemistry edited by Professor F. G. Donnan and the late Sir William Ramsay. It appears to be well translated, and is well printed; and it deals with a most interesting chapter of physics and chemistry. It is not, and does not profess to be easy reading; most of the books on physical chemistry we have come across are child's play compared with this one. The distinguished author has applied the phase rule to the theory of allotropy, both in elements such as phosphorus and in organic compounds such as benzoyl-camphor, but the non-mathematical reader who expects an easy explanation of the chemical facts of allotropy should attempt some more elementary book than this. This book is not written for the general run of chemists who never knew or have forgotten the calculus "by whose grace the elect enjoy their sacred aloofness."

Gesammelte Abhandlungen. *By* Dr. F. Kehrmann. *Vol.* I. *Pp. viii*+203. *Leipzig: G. Thieme,* 1922. *Price paper,* 8*s.*

Chemists are often apt to lose the thread of a prolonged research or series of researches that appear at intervals in detached contributions and often in different journals. This difficulty has been met here and elsewhere by the publication of monographs on topics of special interest connected with different branches of chemistry. The *Ahrens Vorträge* fulfilled this demand to some extent and it was soon followed in this country by the appearance of monographs on biochemistry, physical, inorganic and industrial chemistry. More recently, again in Germany, the series of "Einzeldarstellungen" has added to the number of publications of this type of scientific literature. It is with the object of giving a clear and consecutive account of the large mass of observations which have appeared in various journals that Prof. Kehrmann, of the University of Lausanne, has been induced to collect them together and publish them in a single volume.

The subjects dealt with are mainly two. The first series of reprints, which date back to 1887, have reference to the constitution of phosphotungstic, arsenotungstic and silicotungstic acids and their salts, a subject which has gained in interest since the publication of Werner's theory of complex salts. The second set of papers deals with the quinoneoximes and the effect of various nuclear substituents on their formation, thus affording a notable contribution to the theory of steric hindrance. The majority of these papers have appeared since 1888 in the *Berichte*. J. B. Cohen

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Joural for February* 1)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W.1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Pharmaceutical products, patent medicines	150
Australia, New Zealand	Tinplate, galvanised sheets, enamel ware	113
Belgium	Steel	124
British India	Druggists' supplies, patent medicines	117
Bulgaria	Glass cells, lead, tin, hydrochloric acid (tenders for)	9861/F.E./E.C.
Canada	Whiting	*
France	Leather	128
,,	Raw sugar, palm kernels, groundnuts	129
,,	Iron and steel	18375/F.W./E.C.
Latvia	Fats for soap-making	131
,,	Iron and steel	6820/F.R./E.C.
New Zealand	Copper wire (tender for)	10505/E.D./E.P.
,, ,,	Photographic materials	3164/E.D./C.C.
Norway	Tinplate, terneplates, galvanised plates	140
,,	Vegetable oils	141
Poland	Hæmatite pig iron	6759/F.R./E.C.
South Africa	Hollow-ware	122
,, ,,	Electrical cables and wires	10529/E.D.
Spain, Portugal	Tinplate, tin, earthenware, galvanised sheets, copper sulphate	113
Switzerland	Paper	145
Yugoslavia	Tin	143

* Canadian Government Trade Commissioner's Office, 73, Basinghall Street, London, E.C. 2.

TARIFF CUSTOMS EXCISE

Brazil.—Modifications in the customs tariff affect asphalt, various vegetable extracts, grape sugar, oxides of lead, starch, copper and brass rods and waste, gypsum, and chloride of lime. Certain of the consumption taxes have been increased. Raw material for coal and gold-mining companies, fertilisers, and plant for making paper pulp and for extracting vegetable oils pay only the 2 per cent. "expediente" tax.

British Guiana.—From December 4, 1922, a revised customs tariff has come into force. The specific and *ad valorem* duties are mostly unchanged, but the additions to the specific duties have been increased from 15 to 20 per cent. of the prescribed duties. The *ad valorem* rates on unspecified goods are 16⅔ and 33⅓ per cent. under the British preferential and general tariffs, respectively.

British India.—Opium derivatives may only be exported when the consignment is covered by an official certificate from the country of destination.

Egypt.—Revised valuations have been issued for assessing the duties on various iron and steel goods.

St. Vincent.—Revisions of the export duties affect cotton, starch, sugar, syrup, molasses, groundnuts, and copra.

Sudan.—Regulations have been issued governing the importation of alcoholic liquors.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

The general firmness of the chemical market in view of the unsettled state of Continental politics may be taken as a very hopeful sign, but the depression which might have been expected is no doubt more than counterbalanced by the prospects of shortage of supplies from Germany. A definite settlement of terms in connexion with our American debt is sure to have a beneficial effect on this as on every other trade, and the outlook to-day cannot be considered in any way unsatisfactory when the unstable conditions on the Continent are fully taken into account.

Acid Acetic, 40% ..	£21 per ton. Position very firm, with a strong tendency for prices to rise further. Spot supplies none too plentiful.
Acid Hydrochloric ..	4s. to 5s., carboy d/d.
Acid Nitric, 80° Tw. ..	£25 10s. per ton. Still in very poor demand.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw., is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% arsenical	£6 10s. per ton.
Ammonia Alkali ..	£7 to £8 per ton. Very fair inquiry for both home and export.
Arsenic (White) ..	£70-£75. Still in very limited supply.
Bisulphite of Lime ..	£7 per ton, packages extra and returnable.
Bleaching Powder ..	£10 10s. per ton. In rather better demand, but still very great room for improvement.
Calcium Chloride ..	£6 per ton d/d. Continental supplies freely offered at low prices.
Copper Sulphate ..	£26 10s. per ton f.o.b.
Potash Caustic, 88/90%	£29 per ton.
Potass. Bichromate ..	6¼d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s.-£5 10s. per ton. Home trade no change. Considerable inquiry for export.
Soda Caustic, 76% ..	£20-£21 per ton. Slight improvement maintained.
Soda Crystals	£5 10s. per ton carriage paid. Steady demand.
Sod. Bicarbonate ..	£10 10s. per ton. Improved inquiry.
Sod. Bisulphite, 60/62%	£19-£20 10s. per ton f.o.b. or f.o.r. London.
Sod. Chlorate	Market dull, with offers of Continental make at low prices.
Sod. Sulphide, solid, 60/62	£16 per ton carriage paid. Very quiet.
Sod. Sulphite, Pea Cryst.	£17-£17 10s., 1-cwt. wooden kegs included.
Sod. Acetate, 97/98% ..	£23 per ton.
Sod. Nitrite	£30 per ton 100% basis d/d.

WOOD DISTILLATION PRODUCTS

No alterations in prices are reported this week.

Acetate of Lime—	
Brown	£9 per ton d/d.
Grey	£15 10s. per ton d/d.
Liquor	9d. per gall., 32° Tw., d/d.
Charcoal	£9 10s.-£10 per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw.
	1s. 2d. .. ,, 24° Tw.
Red Liquor	1s. 3d. .. ,, 14/15° Tw.
Wood Creosote	2s. 6d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	7s. ,, ,, 60% O.P.
Solvent	5s. ,, .. 40% O.P.
Wood Tar	£5 per ton d/d.
Brown Sugar of Lead ..	£36 per ton d/d.

TAR PRODUCTS

Acid Carbolic, Crude 60's	2s. 5d. to 2s. 6d. per gall. Numerous inquiries.
Acid Cresylic, 97/99 ..	2s. 3d. per gall. Market active.
Acid Cresylic, Pale, 95%	2s. 1d.-2s. 2d. per gall.
Acid Cresylic, Dark ..	1s. 10d.-2s. per gall.
Anthracene Paste, 40%	7d. per unit per cwt.
Anthracene Oil—	
Strained	8½d. to 10d. per gall.
Unstrained	8d. per gall.
Benzole, Crude, 65's ..	1s. 1d.-1s. 2d. per gall.
Benzole, Standard Motor	1s. 8d.-2s. 2d. per gall. Not much inquiry.
Toluole, 90%	1s. 10d.-2s. per gall.
Toluole, Pure	2s. to 2s. 4d. per gall.
Xylol	2s. 6d.-3s. 6d. per gall.
Creosote—	
Cresylic, 20/24% ..	10d.-11d. Fair inquiry.
Middle Oil	8¼d. per gall. Very firm, with plenty of business.
Heavy	8d. ,, ,,
Standard Specification	7¾d.-9¾d. ,,
Naphtha—	
Crude	9d.-10d. per gall.
Solvent, 90/160 ..	1s. 7d. to 1s. 10d. per gall.
Solvent, 90/190 ..	1s. 7d. per gall.
Naphthalene, Crude—	
Drained Creosote Salts	£6-£9 10s. per ton, according to quality.
Whizzed or Hot Pressed	£9 10s.-£12 10s. per ton, according to quality.
Pitch, Medium Soft ..	135s. to 145s. per ton. Market continues to be very active.
Pyridine, 90/140 ..	11s. 6d.-12s. 6d. per gall.
Pyridine, Heavy ..	8s. 6d.-9s. per gall. Little or no business.

INTERMEDIATES AND DYES

Business in Aniline Dyestuffs during the past week has been considerably better than we have reported for the last week or two. Trade seems to be reviving somewhat and orders are coming in freely. Prices are firm but have not yet risen. This may be imperative in future owing to the rise of various raw materials and coal.

Acid H.	5s. 1d. lb., 100% basis.
Acid Naphthionic ..	2s. 7½d. lb., 100% basis.
Acid Neville and Winther	6s. lb., 100% basis.
Acid Sulphanilic ..	1s. 6d. lb., 100% basis.
Aniline Oil and Salts ..	10d. lb. naked at works.
Benzidine Base	6s. 6d. lb., 100% basis.
Dinitrobenzene	11d.-1s. lb. naked at works.
Dinitrotoluene, 48/50 ..	8d.-9d. naked at works.

Dinitrotoluene, 66/68	1s. 2d.-1s. 3d. naked at works.
Diphenylamine	4s. 1d. lb.
α-Naphthol	2s. 9d. lb.
β-Naphthol	1s. lb.
α-Naphthylamine	1s. 6½d. lb.
β-Naphthylamine	4s. 6d. lb.
p-Nitraniline	2s. 9d. lb.
Nitrobenzene	7½d. lb., drums extra.
Nitronaphthalene	1s. lb.
Naphthionate Soda	2s. 8½d. lb., 100% basis.
Diethylaniline	4s. 6d. lb., packages extra.
Metanitraniline	5s. 6d. lb.
Para Toluidine	5s. lb.
Para Phenylene Diamine	12s. lb., 100% basis.
Meta Phenylene Diamine	5s. 6d. lb.
Meta Toluylene Diamine	5s. lb.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Although the seizure of the Ruhr should, according to economic law, result in higher prices being required by German chemical manufacturers, yet the opposite is being experienced in many cases, due to the manufacturers requiring sterling. Bromides and salicylates, for example, have been offered at lower prices from Germany since France entered the Ruhr district, but these offers are for specified stocks and must soon cease.

Acid Acetic, 80%	£45-£47 ton. Prices advancing.
Acid Acetyl Salicylic	3s. lb. Still a very firm market.
Acid Benzoic	2s. lb. Firm with little spot supply.
Acid Boric, B.P.	£61 ton crystals, £65 ton powder, packages in 2-cwt. bags, carriage paid U.K. Market very steady.
Acid Citric	1s. 7d-1s. 8½d. Market firm, with fair demand. Raw material still inclined to advance.
Acid Gallic	3s. lb.
Acid Pyrogallic	5s. 6d. lb.
Acid Salicylic	1s. 6d. lb. The rise in the cost of carbolic acid will soon necessitate higher prices being quoted for this article.
Acid Tannic	3s. 3d. lb.
Acid Tartaric	1s. 2½d.-1s. 3d. lb., less 5% for English makes. Heavy buying still taking place. Tendency of market upward.
Acetanilide	1s. 6d. lb. Unchanged.
Amidopyrin	14s. lb.
Atropine Sulphate	12s. 6d. oz.
Benzaldehyde, free from Chlorine	3s. lb.
Benzonaphthol	5s. lb., without much demand.
Bismuth Salts	Prices per lb. for cwt. lots are as follows:—Carbonate 13s., Citrate 11s. 7d., Nitrate cryst. 6s. 11d., Oxide 14s. 5d., Salicylate 10s. 5d., Subchlor. 12s. 8d., Subgallate 9s. 6d., Subnitrate 11s. Fairly good market.
Bromides	Some very cheap offers being made from the Continent. Market unsettled.
Chloral Hydrate	4s. to 4s. 3d. lb. for duty pd.
Guaiacol Carbonate	8s. 6d. lb. Chiefly required for export.
Hexamine	3s. 9d. lb. Still very firm with much inquiry.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	No change. Rather quiet, with small demand.
,, ,, ,, B.P.	2s. 5d. lb.
,, ,, ,, Green	3s. 1d. lb.
Magnesium Carbonate, Light Commercial	£40 per ton.
Magnesium Oxide—	
Light Commercial	£85 per ton.
Heavy Commercial	£29 per ton.
Menthol	37s. 6d. lb., less 2½% for original cases. Small quantities 38s. nett.
Methyl Salicylate	2s. 2d. lb. on a firm market.
Methyl Sulphonal	13s. lb. still neglected.
Mercurials	Much weaker in view of the lower cost of quicksilver.
Formaldehyde, 40% Sol.	£98 10s.-£100 ton.
Paraformaldehyde	3s. 6d. lb. Much advanced.
Paraldehyde	1s. 6d. to 1s. 9d. lb. In short supply.
Phenacetin	5s. lb.
Phenazone	7s. lb.
Phenolphthalein	5s. 3d. lb. Slightly weaker in view of larger supplies being available.
Pilocarpine Nitrate	21s. 6d. oz. Slightly lower.
Potass. Bitartrate—99/100% (Cream of Tartar)	98s. 6d.-100s. per cwt. for ton lots, less 2½%. Market firm.
Potass. Iodide	15s. 8d. lb. for cwt. lots. Cases free. Demand still good.
Potass. Metabisulphite	8d. lb.
Potass. Permanganate	8½d. lb. still wanted for good quality.
Quinine Sulphate	2s. 3d.-2s. 4d. oz., bulk packages. Fairly steady market.
Resorcin	6s. lb. Less would be accepted for quantity.
Salol	2s. lb. Much firmer.
Sod. Benzoate	2s. lb. Spot supplies very limited.
Sod. Citrate	U.S.P. quality, 2 mols. water, quoted at 2s. 2d. lb. for cwt. lots. B.P.C. quality, 5½ mols. water, 2s. lb.
Sod. Potass. Tartrate (Rochelle Salt)	82s. 6d.-85s. cwt. Fair demand.
Sod. Salicylate	2s. powder, 2s. 1d. crystal. Still unchanged.
Sod. Sulphite—	
Anhydrous	£27 10s.-£28 10s., according to quantity. F.o.r. London, drums included.
Crystals	£17-£17 10s. ton, according to quantity.
Thymol	17s. to 19s. lb., according to quality.

PERFUMERY CHEMICALS

Amyl Acetate	2s. 3d. lb.
Amyl Butyrate	8s. lb.

Amyl Salicylate	3s. 3d. lb.
Anethol (melting point 21/22° C.)	4s. 6d. lb.
Benzyl Acetate from Chlorine-free Benzyl Alcohol	3s. lb.
Benzyl Alcohol free from Chlorine	3s. lb.
Benzaldehyde free from Chlorine	3s. lb.
Benzyl Benzoate, 19·5° C.	3s. lb.
Cinnamic Aldehyde—98/100% Natural	14s. 9d. lb.
Citronellol	22s. 6d. lb.
Citral, 100%	10s. 6d. lb.
Ethyl Phthalate	4s. 3d. lb.
Eugenol, 100%	11s. lb.
Geraniol (Palmarosa)	30s. lb.
Geraniol	5s. 6d. to 12s. 6d. lb.
Iso Eugenol	17s. lb.
Linalol ex Bois de Rose	21s. lb.
Linalyl Acetate	22s. 6d. lb.
Methyl Benzoate	8s. 6d. lb.
Phenyl Ethyl Acetate	10s. lb.
Phenyl Ethyl Alcohol	17s. 6d. lb.
Rhodinol	45s. lb.
Terpineol	3s. lb.

ESSENTIAL OILS

Almond Oil	2s. 6d. lb. Quiet.
Anise Oil, Red Ship Brand	2s. 1d. lb. forward., 1s. 10d. to 1s. 11d. c.i.f. In poor demand,
Bergamot Oil	12s. lb. forward, 11s. 3d. to 11s. 6d. c.i.f. Quiet.
Bourbon Geranium Oil	26s. spot, forward 22s. 6d. Very firm, with good enquiry.
Camphor Oil, White	85s. cwt. No change. No Brown offering.
Cananga Oil, Java	9s. to 10s. lb.
Cinnamon Oil, Leaf, Ceylon	4d. to 4¼d. oz. Inclined to be easy.
Cassia Oil, 80/85%	8s. 6d. to 8s. 7½d. lb. Very strong demand. Spot stocks low.
Citronella Oil, Java, 85/90%	3s. 6d. lb. Steady.
Citronella Oil, Ceylon	3s. 1d. to 3s. 3d. lb. Advancing.
Clove Oil	7s. 3d. lb. Inclined to be easy in harmony with the market for spice.
Eucalyptus Oil, 70/75%	1s. 6d. to 1s. 10d. lb.
Lavender Oil	11s. 6d. to 13s. 6d. lb., according to percentage.
Lemon Oil, Spot	2s. 10d. to 2s. 11d. New crop for shipment 2s. 9d. More enquiry and slightly firmer.
Lemongrass Oil	2½d. oz. spot. Very quiet.
Orange Oil, Sweet	8s. 6d. to 9s. 6d. Quiet.
Otto of Rose Oil	20s. to 25s. oz.
Anatolian	24s.
Bulgarian	28s.
Palma Rosa Oil	17s. 6d. lb.
Peppermint Oil—English	70s. to 80s. lb.
Mayne County	13s. 6d. lb.
Japanese	7s. 3d. to 7s. 6d. lb.
Pettigrain Oil, Paraguay	7s. 6d. lb.

TRADE NOTES

Sampling of Imported Goods for Test as to Liability to Customs Duty

The Commissioners of Customs and Excise desire to draw the attention of importers and agents to the fact that when chemicals or other articles of value are sampled by their officers for the purpose of determining by analysis the question of liability to customs duty, any portion of the sample which may remain unused by the Government Chemist will be returned to the importer if a request to that effect is made to the officer at the time of sampling. In this connexion the Government Chemist desires to point out that the quantity used for test would in many cases be substantially reduced if importers would assist by furnishing information to the best of their ability as to the constituents of the articles sampled. Such information will be treated as confidential, and if preferred may be forwarded direct to the Government Chemist, Government Laboratory, Clement's Inn Passage, London, W.C. 2.

The Commissioners desire further to observe that in the case of compound articles not chargeable with duty as a whole, but merely in respect of one or more dutiable ingredients or parts, the assessment of duty would be materially facilitated and delay consequently avoided, if arrangements could be made for the value of the dutiable ingredients or parts to be shown on the invoice in addition to the total value.

An International Bill of Lading

The text of the draft International Bill of Lading Convention, passed by the Diplomatic International Conference at Brussels in October last, with a short history of the events leading up to drafting of this Convention, are contained in a booklet just issued by Messrs. Furness, Withy and Co., Ltd., a member firm of the Federation of British Industries, for the benefit of shippers and consignees. An earlier publication containing the text of the Hague Rules, 1921, upon which the International Convention is based, was in wide demand in shipping circles.

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES London, February 16, 1923 No. 7

EDITORIAL

PROFESSOR VON RÖNTGEN, whose death we regret to announce, made important discoveries and did much to increase our knowledge and to benefit mankind. He made such an addition to the earlier work of Crookes and Lenard as to well deserve the fame to which he attained. These workers had investigated the electric discharge in highly exhausted tubes containing a little gas, and they showed how cathode rays, which we now know to be discharges of units of negative electricity, were given off and how these could be studied and made use of. Professor Röntgen discovered a new radiation started by the discharge of cathode rays against a solid substance. A vibration, or radiation, is set up in the solid and communicated to the neighbourhood; this new vibration has a very short wave-length corresponding to the extreme ultra-violet spectrum of light. Its waves are so short that they can penetrate through solids opaque to ordinary light, but they have a considerable photographic power so that records may be taken, as Röntgen himself showed, of the structure of various opaque bodies, and by means of the developments made by Moseley, von Laue, the Braggs, and others, we can now obtain a photographic guide to the internal structure of opaque or transparent crystals. Röntgen was assistant to Professor Kundt at Würzburg, Professor of Mathematics and Physics at Hohenheim, Professor of Physics at Strasbourg, Giessen, Würzburg, and finally Munich. He received honours in many countries, and lived a long and useful life. His discovery, so soon as it was published, attracted unusual attention, and its possibilities in surgery, the arts and sciences, and in manufacture were at once apparent. In its scientific uses it has recently been supplemented by the positive ray, which in the hands of Sir J. J. Thomson and Dr. Aston, has led to such valuable results. The simplicity of X-ray work rendered its adoption in many branches of research speedy and widely spread.

How the X-ray photographs have helped surgeons to locate fractures, foreign bodies, or the results of disease, is known to us all. The extent to which X-rays will be of value in effecting cures is still a matter of doubt, but that Professor Röntgen's discovery has done much to alleviate human suffering is not open to argument. It was only last month that we recorded the discovery of a new element by means of X-ray spectrum analysis, and it may be confidently stated that X-rays have been as important to scientific investigations as they have been to the surgical and medical professions. During the last thirty years such great and interesting advances have been made in our knowledge of the various vibrations which matter can produce under suitable conditions that a whole new domain of science has been rendered available for exploration. Whatever discoveries will be made in the future, the work of the earlier workers will remain the starting point for those who succeed them. The advance of science would be impossible but for the outstanding discoveries of logarithms, the calculus, the microscope, the spectroscope, the Wheatstone bridge, the dynamo and the steam engine. On that splendid roll which includes the names of Napier, Newton, Liebnitz, Watt, Descartes, Crookes, Darwin, and Pasteur, Fame will also inscribe that of Wilhelm Konrad von Röntgen.

* * *

It is announced that the French Chamber of Deputies has, at last, passed the Bill authorising the convention concluded by Monsieur Loucheur in 1919 with the Badische Anilin- und Sodafabrik for the grant of a concession to manufacture synthetic ammonia at Toulouse by the Haber process. The imminent presentation of the above Bill was recorded in this *Journal* so long ago as in May, 1921, and the delay in obtaining official approval of the project has been due to no small extent to the sharp controversy over the respective merits of the rival Haber and Claude processes. Now, apparently, the controversy is to be decided by the sole final test, that of economic competition and, in view of the propaganda which has been conducted in favour of both processes in this country, the results will be awaited with interest, especially as it is understood that a modified form of the Haber process is actually being worked in the North of England. As might be expected, a storm of controversy has been raised in Germany by the passage of the Bill and the announcement by M. Loucheur that even if Germany refused to deliver the plant France had the necessary technical data to enable the installation to be erected and operated. The German Press angrily accuses the directors of the Badische Co. of having betrayed their country for 11,500 million marks (at present rates!) to the "hereditary enemy." But, as a correspondent of *The Times* remarks, the real source of this anger is the knowledge that ammonia is an essential ingredient of explosives, and significant reference is made to the heavy penalties imposed on two German chemists who tried to sell the secret of a certain dye process to American interests. We hope shortly to publish an account, contributed by our correspondent in Paris, of French views of the situation.

* * *

In our correspondence columns Prof. W. A. Bone draws attention once more to the desirability and urgency of finding a solution of the smoke problem. Prof. J. B. Cohen and Prof. H. E. Armstrong have already contributed opposing views on the subject, and Prof. Bone, who disagrees with the views of Prof. Cohen and supports those of Prof. Armstrong, suggests that as "coal and its combustion is a chemical matter," the Society of Chemical Industry should set up a committee to find some really practical solution of the problem that would command serious consideration. That the discovery of a really practical method of abating the smoke evil and ensuring economy in fuel consumption is no easy task is shown by the fact that two such distinguished chemists as Prof. Bone and Prof. Cohen fail to agree on the subject. Further, in view of recent experience of the Governmental attitude towards such questions, it is legitimate to wonder whether "departmental interference" would not nullify the effect of the constructive suggestions which would be evolved by such a committee. With these points in mind, we commend the pioneer work, mentioned by Prof. Bone, of the Technical Sub-Committee of the Federation of British Industries in advising manufacturers on fuel economy and smoke abatement. It is on such lines as these, directed towards enlightenment rather than compulsion, that we feel the question will ultimately find solution, for the problem is primarily one of economics and only secondarily one of sentiment. In the meantime, however, the pollution of our skies and the waste of our prime asset, coal, continue, and until these blemishes on our scientific reputation are removed constructive suggestions from our readers will be welcomed.

SOME EARLY YEARS AT THE CHEMICAL SOCIETY

BY SIR WILLIAM A. TILDEN, F.R.S.

EVERY Fellow knows that the Society was founded in 1841 and that the first President was Thomas Graham. But there are not many now remaining who have any personal recollections of the men or the doings connected with the first years of the Society, the oldest of the kind in the world. It was not a time of the greatest intellectual activity. On the Continent Dumas, in France, and Liebig, in Germany, were the chief authorities, and the great events on which public attention was concentrated were the International Exhibitions, of which the first was held in 1851 and the second in 1862. The first I remember only dimly, being a child at that time, but the two great exhibits were the Koh-i-noor and the great nugget of gold from the newly-discovered Australian goldfields. Of the second I have vivid recollection chiefly concerning the magnificent display of crystallised coal-tar dyes, the discovery of which had much to do with increased activity in the chemical world.

Previously to this time there were but few communications made directly to the Chemical Society, as all the chemists then engaged in research preferred to send their results to the Royal Society. The *Journal* of the Chemical Society during the first few years was made up chiefly of papers from foreign sources and from the Philosophical Transactions of the Royal Society. In 1862, however, a new series of transactions was started under the editorship of Henry Watts, who soon afterwards began the compilation of his famous dictionary. In 1862 I entered the private research laboratory of Dr. John Stenhouse in Rodney Street, Pentonville, and to him I owe my first introduction to the Chemical Society. Stenhouse has never received from the British chemical world the credit which is his due. A pupil of Liebig at Giessen, his first paper is dated 1839, and from that time till 1863 the catalogue of scientific papers attached to his name contains no fewer than sixty-four distinct memoirs almost entirely on subjects connected with organic chemistry, the most important of them relating to products from the lichens. A very remarkable record at any time, but all the more so when it is remembered that having been lecturer in chemistry at St. Bartholomew's Hospital, he was in 1852 deprived by a stroke of paralysis of the use of his limbs, so that from that time forward he was unable to perform any operations with his own hands, and was dependent wholly upon assistants. This did not, however, extinguish his enthusiasm in the pursuit of science. The constitution of one of the substances left by him has recently been made out by M. O. Forster (Picrorocellin. *Trans.* C.S., May, 1922, p. 816), and Field's rhymes in the little pamphlet called "A Chemical

Review," printed in 1863, bear witness to his fresh activity:—

> Stenhouse the veteran, game as any bird,
> We hail once more thy voice to science heard,
> Linguist of lichens, each fair herb and flower
> Hath yielded trophies to thy chemic power, etc., etc.

It was then owing to the influence of this good man that I was led to attend the meetings of the Chemical Society and though not yet twenty-one and really very ignorant, I can recall the meetings of those days, and in the mind's eye can see many of the men who were the leaders of the time. The meetings were held in a part of the building then undergoing reconstruction, the ground floor of which has since become the entrance to the RoyalAcademy. Visiting the building now, no trace of the meeting rooms can be discovered, as they have disappeared in the rearrangement of the entrance hall and adjoining apartments. The two rooms assigned to the Chemical Society were on the right of the main entrance, and appear to have been merged in the space where catalogues are now sold. There was, first, a small library, and it was used as a place of assembly, from which Fellows passed directly into the meeting room furnished with benches and a table, behind which the secretaries and the President sat. The first president I remembered was Hofmann, then a young and bustling personage, while the secretaries were Odling, a smart young man who often appeared in a white waistcoat, and had a lively way with him, and a disposition to treat things as a joke, which some of his seniors like Williamson, afterwards President, were inclined to regard seriously. His colleague was Redwood of the Pharmaceutical Society, a very dull personage who never offered a remark and is well described by Field as having a "stolid look and philosophic mien." He was succeeded as secretary by Harcourt and after this date seldom appeared.

Of the regular attendants at the meetings I can remember Perkin, a black-bearded man, one of the few who regularly engaged in research and brought papers to the Society, some of which, beside those on mauve and other colouring matters from coal tar, were of great theoretical and practical importance. Then there was Matthiessen, at that time lecturer at St. Bartholomew's Hospital whose researches on the preparation of the metals of the alkalis and alkaline earths by electrolysis resulted in the specimens of lithium and other metals which it is believed still exist in the chemical collection at the Imperial College of Science at South Kensington. He suffered from a nervous affection which caused twitching in the face and he died unhappily in 1864. He was an able man and an active worker. "Clever Müller, bald before his time," was a frequent attendant, also Abel, Frankland, Russell and others, whose figures I cannot now recall In those days, it must be remembered, ideas of constitution were based chiefly on the theory of types, and discussions at the meetings of the Chemical Society turned very often on the question as to which type particular compounds should be referred. I remember, for instance, a speaker saying, "you might as well refer nitrous oxide to the ammonia type," and the rejoinder of Odling with a smile, "I certainly should," after which the speaker shut up. Soon after this the influence of Gerhardt led to the recognition of the law of Avogadro, so long neglected, and the clear distinction between atoms and molecules, was at last recognised. Previous to that time, though the methods of taking vapour densities had been taught in the chemical schools, no one seems to have realised what they meant and the results were used chiefly to control the analysis of volatile compounds. The successful synthesis of such a compound as coumarin by Perkin was, therefore, an important achievement in the days of ignorance and uncertainty in which the paper was read to the Chemical Society, though probably this was not realised by the chemists who were present.

A great advance which had its effect on ideas in chemistry at that time arose out of the introduction of the spectroscope and the consequent discovery of the metals rubidium and cæsium and a little later thallium. The discovery of thallium by Crookes was, in the first instance, communicated to the columns of his own paper, *The Chemical News*, and afterwards to the Royal Society. Crookes was not at that time a regular visitor at the Chemical Society's meetings.

In 1864 appeared the two perhaps most active members of the Chemical Society—namely, J. A. Wanklyn and Ernest Theophron Chapman. The latter, a few years later, lost his life in an explosion at a chemical works in the Harz. But, for the first few years, they jointly kept up an almost uninterrupted series of papers to the Chemical Society, and, undoubtedly, did good work, which raised questions contributing in no small degree to the progress of chemical theory in England.

One of the earliest recollections I retain is of the lecture delivered before the Society in the rooms of the Royal Society, adjacent to those of the Chemical Society, by Berthelot on the subject of organic synthesis. Williamson, the new President, was in the chair, and the lecture, delivered in French, was illustrated by experiments. Here, for the first time, I remember seeing the absorption of carbonic oxide by hot caustic potash and other experiments. This was in the summer of 1863: a translation of the lecture is printed in the *Journal* of the Society for 1864.

The strength of the Society at that time was under 400, with a few Associates, a class of members which has since disappeared. The progress of the Society had been comparatively slow, both in numbers and in finance. It is true that some important contributions to science had been recorded as, for example, Williamson on etherification in 1851, but the number of men who were steadily devoting themselves to research was very small, and of these many devoted themselves to mere analysis of natural products such as tea, or enquiries into the composition of water supply, and questions of more or less practical importance. Even so late as 1864, water analysis was a subject which was frequently discussed, and a year or two later I remember being sent by the editor of the *Pharmaceutical Journal* to the Royal College of Chemistry in order to see the apparatus introduced by Frankland and Armstrong for use in their process. The article in the *Pharmaceutical Journal* in 1868 was probably written by me.

During the years referred to, the Society continued to meet in the rooms already described within the precincts of Burlington House, which had then become the property of the Government and was undergoing reconstruction with the view of providing accommodation for the Royal Society and other learned bodies, but it was not till 1874 that Professor Odling, then President, was able to congratulate the Society on having entered into possession of the rooms, which it has occupied ever since, and which he described as satisfactory in all respects except the meeting room. In 1882 alterations were introduced which converted the room into what it is now, with the presidential chair at one side and the seats for the Fellows all on a level. The lapse of time, however, has led to immense accessions to the number of Fellows and especially to the books in the Library, in consequence of which the rooms can no longer be considered so satisfactory as they were represented by Odling fifty years ago. Since that time, the Fellows of the Chemical Society have increased from a few hundreds to nearly four thousand, and the library, now used by members of several other societies, has grown proportionately, so that the apartments assigned to the Society by the Government are altogether insufficient for its every-day accommodation.

In this review one matter deserves to be mentioned, though I took no part. This was the existence of the dining club called the Bs, which met for dinner at 6 o'clock at the "Cheshire Cheese" and afterwards at the "Rainbow," Fleet Street. The club came to an end in the early 'seventies, but was soon followed by the formation of the "Chemical Club," of which the first secretary was Alexander Pedler, who continued to act until he went to India.

FROM HIDE TO LEATHER*

BY S. HIRST

THE object of tanning is to render stable and non-decayable animal skin, which in its original condition is easily putrefiable, to give it toughness and pliability, at the same time making it waterproof and durable.

The original pelts are of a very complex chemical nature, but by combining them with tanning agents definite chemical compounds are produced. These tanning agents are divided chiefly into two classes—vegetable and mineral tannages. Roughly speaking sole and upholstery leather is mostly vegetable tanned and upper leather and fancy leathers are mostly chrome tanned. Whichever process is used, certain stages in the process are common to both.

The raw skins are received by the tanner in various conditions. Some are delivered fresh from the butcher, others, which have to be kept for a time, must be heavily salted to preserve them, but in hot countries, where transport is difficult and salt is not easily procurable, the hides or skins are dried. The first thing the manufacturer has to do is to bring back these skins as nearly as possible to the state they were in when they were taken off the animal, and to accomplish this they are soaked in water.

When soft, the pelts are put into lime liquor. The liming process, and in the case of sole leather, the subsequent tanning, is usually carried out in pits sunk in the ground. Liming serves several purposes. It enables the hair to be removed, and it opens the fibres of the pelt, removing at the same time some of the cementing substance which binds the hide fibres together. Where the finished leather is required to be firm, the object in liming is to remove as little hide substance as possible from the pelt, but by means of the alkaline liquor, to swell the skins to their full original natural state, and saponify any of the natural grease that might otherwise show in the finished leather. Where the final leather is required soft, more of the internal hide substance is removed in the lime, and not so much attention is given to plumping the skins.

The next operation is to remove the loosened hair, and then any adhering flesh and tissue from the other side of the skin. Formerly, unhairing and fleshing was accomplished by hand, but now these two operations are usually carried out by machinery. It should be remarked that of the two sides of a hide or skin the "grain" is the outside on which the hair grows, and the "flesh" is the inside lying next to the animal. The skins of different animals have quite distinct and characteristic grain formations, and in this lies a means of identifying the skin from which a certain leather is made.

Having completed the liming process and cleaned the pelts of hair and flesh, they are now ready for tanning. Lime left in the skins after the liming process must, however, first be removed, and this is accomplished by the use of acid solutions. Different classes of leather require different treatment at this stage. In the case of sole leather, in which good substance is required, it is not desirable to remove completely all the lime, or the hides will fall and the substance be reduced, but for soft upper leather, all traces of lime are removed. With the finer leathers, such as glazed kid, in which the skins are required very soft and flaccid, deliming is accomplished by the use of fermentative substances such as dog-dung, though synthetic substitutes have been introduced with a view to overcoming the disagreeable nature of this operation.

---

*Abstract of a paper read before the Bristol Section on Nov. 2, 1922

There are many methods of tanning different skins, and many agents capable of converting pelt into leather. The two most important methods of leather manufacture are, however, the vegetable and chrome tannages. The vegetable tannage is the oldest method, and to-day finds its chief importance in the production of sole leather, though there is also chrome sole leather. Vegetable tanning materials are many and varied, and consist of woods, barks, leaves, nuts and pods of several trees. Enormous quantities are imported from all over the world.

Although some of these vegetable tanning materials are received in the natural dried condition, vast quantities of solid and liquid extracts are used. These extracts are prepared by extracting the tannin from the raw materials with water, and concentrating the liquor thus obtained by evaporation.

Vegetable tanning consists in soaking the hides in infusions of these various tanning materials, different results being obtained by the use of different materials. The hide fibre absorbs the tannin, combining with it to form leather. The tanning liquors are prepared by leaching the tannin from the dry materials with water, and by dissolving tanning extracts, the desired results being obtained by blending.

The goods first of all go into very weak tan liquors, and proceed through the tanyard gradually, being removed into liquors of increasing strength until they are completely tanned. Too strong tan liquors have to be avoided at the commencement of the tannage, as the result would be to tan the surface of the hide too quickly, impeding tannage of the interior, and producing what is known as case-hardening. The aim in tanning sole leather is to produce a firm, solid and well filled leather, which is sold by weight. It must not be too heavily, nor yet too lightly tanned, and the demand for an article of good colour has to be borne in mind throughout all the processes.

Sole leather, of course, takes much longer to tan then dressing leathers, which receive a much shorter tannage, and are then curried with oils and fats. For upper leather (glazed kid for instance), which is sold by measurement, the tannage is very much lighter, and is completed in a very much shorter period. In dealing with vegetable tanned sole-leather, when the tannage is complete, the hides are left to drain for a while, and are then taken to the drying sheds. Before hanging up to dry they are given a coating of oil, which is usually cod oil, as this has been proved to be generally the most satisfactory. If the leather was dried out at this stage and used on boots, it would not resist water, would not stand hard wear and would get spongy in the damp. This is overcome by half drying the leather, and then laying it down in piles. In this process the moisture inside gradually becomes equally distributed throughout the pile, and the leather takes on a sort of indiarubber feel. Great care has to be exercised in bringing the goods to the correct temper for different processes. First of all they are struck out to make them smooth, and then in a dryer temper they are rolled under a heavy roller, which in their medium moist state solidifies the leather. It is then hung up and after drying is ready for use.

For vegetable tanned soft leather, such as is used for gloves, etc., the process would roughly be the same, viz.: Having removed all traces of lime by treating with acid, the skins would be tanned in weaker liquors made from materials which do not yield quite so hard or solid a leather, and would from this stage follow very much the same process as will be described under chrome tannage.

In the preparation of skins for upper leather, after liming and removing the hair and cleaning the flesh, every trace of lime is removed. In this state the skins will not keep long, and must be tanned as quickly as possible. Here again the process varies according to the nature of the skins, and the use of the finished leather, and this leads up to chrome tannages.

When goat skins are converted into glazed kid, the two-bath process is used, but chrome tanned leather for most other purposes is treated in the one-bath process. Chrome sole leather is made by the one-bath process, in which the hides are tanned in a basic chrome-salt liquor. This tannage is only a very light one, and weight and water-resisting properties are then imparted to the leather by impregnating it with hot waxes. The production of chrome sole-leather is a very much shorter process than that of vegetable-tanned sole leather.

In the two-bath chrome tannage the skins are first put into a chrome liquor, which is made by dissolving bichromate of potash or of soda in water, and adding hydrochloric acid. This turns the skins a brilliant yellow colour, due to absorption of the chromic acid. From this bath they are transferred to a liquor consisting of a solution of hypo and acid. The sulphurous acid evolved causes reduction of the chromic acid, which is fixed in the fibre as a basic chrome salt, the skins becoming blue coloured, and sulphur is deposited in the leather. It should here be remarked that in the manufacture of these lighter classes of leather, mechanical means are employed, and the tannage and subsequent operations are usually conducted in revolving drums or paddles. When the chrome tannage is completed, the skins are removed and thoroughly washed free from acid. The next process is dyeing, and if the skins were dried out at this stage, the leather would become hard and unworkable. To remedy this the skins are thoroughly drummed in a fat-liquor, which is an emulsion of soap and oil in water. After this they are dried out, stretched by machine to make them soft, and are then ready for finishing, the final operation to produce glazed kid being that of glazing the grain.

Careful control of the processes is necessary at every stage of manufacture. For instance, in the early stages in soaking back the pelts ready for liming, if the salt is not removed there will be a tendency for the pelt to remain tight and not swell properly. Too much soaking will result in the loss of hide substance, and the finished leather will be poor or thin and hard. Over-stale soaks, especially in warm weather, can result in considerable loss of hide substance in a comparatively short time. The same loss has to be guarded against, especially in the case of sole leather, in the liming liquors. These liquors do not discriminate in their solvent action on the hair roots and cementing substances, which it is required to dissolve, and true hide substance, and here the chemist is up against a difficulty as the Kjeldahl method will only show the total dissolved nitrogenous matter and does not discriminate between those substances which it is desired to remove and those which should be retained. Under-liming will not open up the fibres of the pelt properly for the ensuing tannage, whilst excessive liming will result in loss of hide substance and will produce a harsh-natured leather. Ammonia is, of course, evolved in the action of the lime liquor on the hide, and an excessive smell is a pretty sure indication that pelt is being lost. When skins are being prepared for upper leather, insufficient liming tends to produce a hard horny leather, which cannot be remedied.

Deliming processes also require very careful control. In the case of sole leather if all the lime is immediately removed the pelt falls and the substance, which is required plump, is reduced, but if lime is free on the surface of the hide when it is introduced into vegetable tan liquors a tannate of lime is deposited in dark brown patchy stains which unfortunately remain right through the process, spoiling the appearance of the finished leather and leaving it "cracky" if present in excess.

Where fermentative substances, such as dog-dung, are employed for deliming, as in the case of goat skins for glazed kid, even greater care is necessary, and the time and temperature factors have to be very carefully controlled. So rapidly can the bacterial activity develop, that lack of control can result in very serious loss.

The water supply is one of the most important considerations. A hard water containing a large proportion of lime salts, will certainly result in loss of tannin, and probably discoloured leather, if vegetable tanned. As is well known, iron salts react with tannin to give black-coloured stains, and so intense is the reaction that even a trace of iron in the water supply, or introduced from any other source, is fatal to the production of vegetable-tanned leather of good colour, and must therefore be strictly guarded against.

Vegetable tan liquors are all liable, in varying degree, according to the materials used, to fermentation with the production of acid. These acids serve to remove any lime remaining in the hide, and at correct concentrations they plump the fibre so that good substance is obtained, and it is therefore necessary to control and adjust the acidity to obtain the desired results. Too much acid, and in particular mineral acid, will result in hard leather, which will easily crack when dry, one of the dangers to be most strictly avoided.

In light leathers like glazed kid, which are tanned by the two-bath chrome process, washing free from acid after the hypo reducing-bath is very important, as any acid left in the skins will act on the fat-liquor forming fatty acids, which will ultimately "spue" out of the leather and show as a disagreeable greasy exudation on the surface of the finished leather.

Temperature plays an important role, but chrome-tanned leather will withstand much higher temperatures than vegetable tanned. The use of too hot liquors in the production of vegetable-tanned leather will shorten and destroy the fibre, and result in tender leather. On the other hand, successful dyeing, and fat-liquoring operations in the case of chrome-tanned leathers must be carried out in quite hot liquors. The fibre is not damaged, and, indeed, one of the tests as to whether a skin is properly chromed is to boil a piece in water. If the tannage is correct, the nature of the skin will not alter, whereas a piece of vegetable-tanned leather would be completely ruined.

Similarly, much higher temperatures can be utilised in the drying sheds to dry chrome leather, which, therefore, will dry more quickly than vegetable-tanned leather. If the latter is dried at too high temperatures, especially in the beginning, when the leather is wet, it will be likely to be hard and cracky when finished. The drying and finishing of vegetable-tanned leather (sole leather) presents many difficult problems. Oxidation of the surface tan liquor will result in dark colour. Chill winds and draughts must be guarded against, the atmosphere must not become too charged with moisture, and the possibility of mould must be precluded. Many types of plant have been devised to secure perfect drying conditions.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments of his contributors, but does not necessarily agree with them.

STILL MORE LETTERS

have reached me in reply to my question as to the outstanding discovery of the past thirty years or so. I am very much obliged to my correspondents, and welcome the interest shown in these columns. May I suggest to all of them that as their numbers seem to be increasing that their communications should be addressed to the Editor of this paper and marked "Eye-Witness" on the left hand top corner of the envelope. This will enable me to receive them by an early post and to comment at once on any items which may be of urgent as well as of sufficient general interest.

THE FIXATION OF ATMOSPHERIC NITROGEN

receives the first place in this week's letters. One or two of the writers are fearful lest I should overlook this great achievement. It is pointed out to me that at least four conditions must be fulfilled in order that a process may rank as a first class applied chemical achievement. (The word I used was "discovery," but let that pass.) It must be developed initially on sound scientific lines; it should show engineering skill; it should yield a product of wide utility; the product should be made at only a reasonable cost. I suppose the contact process for the manufacture of sulphuric acid fulfils each of these requirements, and also the catalytic production of hydrogenated oils, and possibly the Bakelite process satisfies the conditions. Pre-eminent, however, stands the synthetic ammonia process for the brilliance of the application of physical chemistry to its solution, and for the wonderful engineering skill displayed. But greatest of all we must recognise the profound influence which a cheap source of ammonia will exert on the most vital problem of the feeding of the rapidly growing population of the world by the intensive cultivation of the land with the aid of fertilisers.

POETICAL CONTRIBUTIONS

"R.T.M.H." seems to be unwilling to profit by the excellent counsel I recently gave him—or is it perhaps her? In his letter this week I notice no sign either of gratitude or of repentance. He denies the youth with which I credited him and I suppose he is:—

> "Now in wintry delights and long fireside meditation
> 'Twixt studies and routine paying due court to the Muses."

But a weekly scientific journal is for the diffusion of useful knowledge, not the gratification of poets—whether spring or otherwise. Let him consider the large majority of our readers, grave men thirsting for knowledge, who unroll this ample page rich with the spoils of time. What is it *they* desire?

> "The unhappy man, who once has trail'd a pen,
> Lives not to please himself, but other men."

"R.T.M.H." has indeed pointed out an error which probably the printer and everyone else concerned noticed so soon as the *Journal* was printed, but he has written nothing in answer to my warning which is at all to the point. Let him contribute a few articles to the *Philosophical Magazine* or translate Professor Smits' book on Allotropy into Esperanto, or do something else really useful and not squander his opportunities in frivolous verse. If, on the other hand, he cannot keep away from poetry, let him render Dr. Hicks' brochure on "The Analysis of Spectra" into harmonious hexameters; a nice little pocket edition of these would be a popular book, and if "R.T.M.H." is engaged in industry he should dedicate it to the Chairman of his Company; he may be rewarded by a seat on the board. Stranger appointments have been made!

I trust the Editor will not be too lenient with regard to flippant remarks or jesting rhymes; a due proportion should be observed between the suet and the currants, and we have not all got a sweet tooth.

THE CLERGY IN SCIENCE

I was very pleased to read a contribution in our journal from a north-country clergyman. I don't happen to know the district he describes, but it seems to be a pleasant one. Country parsons have often had the time and the inclination to work at Science; there were Gilbert White, who wrote the "Natural History of Selborne," Kirby the entomologist, and many others. And plenty of clerics have made valuable additions to Science—Pascal, Sedgwick and Priestley, if one's definition of a cleric is wide enough to include Roman Catholics and Unitarians. But the most striking example is perhaps Watson, who was Professor of Chemistry at Cambridge, afterwards Regius Professor of Divinity there, and finally Bishop of Llandaff, or Landaff as he always spelled it. I remember being rather interested to read how some time towards the end of the eighteenth century he discovered a means of improving the manufacture of charcoal and increased the efficiency of gunpowder so that a cannon could fire a sixty-pound cannon ball some 270 feet, about a hundred feet further than was previously possible. The range of artillery has improved a good deal since then. But whether the destruction of mankind is a suitable study for a bishop is open to question. I have a sort of idea that Schönbein discovered gun-cotton, but am not at all clear who made the other discoveries about explosives. Perhaps someone will tell us about these.

FORTHCOMING EVENTS

Feb. 15. The Institution of Mining and Metallurgy, the Rooms of the Geological Society, Burlington House, W. 1, at 5.30 p.m. "Liquid Oxygen in Mining," by A. James. "The Aneroid Barometer and Barograph in Engineering," by R. H. L. Lee. Succeeding General Meetings on March 15, April 19, and May 17.

NEWS FROM THE SECTIONS

BRISTOL SECTION

The fifth meeting of the Session, held at Bristol University on Thursday, February 1, took the form of a joint meeting with the local Section of the Institute of Chemistry. Dr. F. W. Rixon presided over a large gathering, and Mr. Edward Russell, City Analyst for Bristol, read a paper on "The Necessity for a Change in the Milk Standard."

Mr. Russell said that milk standards first began to be applied in the middle of the nineteenth century, as the result of a Royal Commission's investigation. The instruments used then were rather crude compared with those in use now, but it led to an Act, which was passed in the 'sixties, which left no general standard. In 1874 general standards for various foods were fixed, the standard for milk being 9·0 per cent. of solids and 2·5 per cent. of cream, but in the 'eighties the standards were altered to 8·5 for solids and 2·75 for fat. Even then, however, there was no means of estimating fat accurately. The position now was that a man must be proved to have tampered with the milk before he could be fined in a court of law, but it was felt that the standard was still inaccurate. Improved processes had been developed, and it was found that good milk should contain 8·5 per cent. of solids and 3·5 per cent. of fat. In 1891 a standard was fixed by the Board of Agriculture stipulating 8·5 per cent. of non-fatty solids and 3 per cent. of fat. An average sample should contain, per cent., 3·9 of fat, 3 of casein, 4 of albumen, 4·75 of lactose and 0·75 of ash. There was no such thing as one standard combining the fatty and non-fatty solids. The composition of milk varied, both when taken from a single cow and when taken from a whole herd. In a number of tests he made recently, Mr. Russell found that the yield of 22 per cent. of 30 or 40 cows gave below 3 per cent. of fat on the morning's milk. There was a risk in taking 3 per cent. as the standard, some injustice might be done, and there were arguments that the standard should be reduced. But for blended milk, including the morning and evening milk of a herd, although there might be a hard case now and then, the 3 per cent. standard should be maintained. There were variations at various periods of the year, but the range might be taken as from 3 to 4 per cent. of fat and 8·4 to 9·2 per cent. of non-fatty solids. The average fat content shown was 3·4 per cent. in January; there was a fall until June, and the records rose in July until September, when there was a slight fall, but the average rose again until the end of the year to 3·75 or 4 per cent. A consideration of the seasonal curves for herds that had been milked and fed properly, suggested that the present standard was too low rather than too high. There was a similar alteration in the curves for non-fatty solids. In revising the standard the figures should be left as they were for January until the autumn and then strengthened, as the autumn milk was richer than in the rest of the year. There was a much bigger proposition, *i.e.*, whether milk was clean. Upon that a great deal of investigation had been carried out. He had prepared a table as the result of his experiments, but the Government had thrown over standardisation and decided upon a scheme by which milk might be sold in different classes, such as pasteurised milk. He suggested that standards of sediment and bacteria should be instituted for vended milk.

In the ensuing discussion Mr. O'Brien said that if the standard of fat were raised it would operate against farmers keeping breeds of cattle that gave large total yields of milk in which the percentage of fat was known to be on the low side and would also tend to make milk dearer. It was well known that when cows were milked at irregular hours, say at 6 a.m. and 4 p.m., there was a decrease in the percentage of fats. That occurred especially on Monday morning, because the cows had been milked earlier than usual on Sunday.

Mr. Russell, in replying, said that whilst economic considerations might induce farmers to keep cattle that gave a large yield, they could maintain the general standard of cream by including some Channel Islands cows in their herds.

Another speaker remarked that when cows had calves running with them they were not milked to the fullest extent. Some of the milk was left for the calf, and that portion contained the larger percentage of cream.

Dr. Rixon, in proposing a vote of thanks to Mr. Russell, said that the doctors disagreed about the sterilisation of milk, as boiling the milk destroyed the vitamins and boiled milk did not help the persons drinking it to develop the powers of germ resistance so much as unboiled milk did.

SOUTH WALES SECTION

Prof. Thompson presided at the meeting held in Cardiff on February 2, and Mr. E. A. Rudge, B.Sc., read a paper entitled "Notes on the Manufacture of Crucibles." Investigations on the physical properties of clays and graphites in mixtures were described, and it was pointed out that the measurement and definition of plasticity and refractoriness are still in an unscientific state, being based on empirical and loose standards. In discussing the process of weathering it was suggested that this seems to be connected with the fermentation of organic matter and oxidation of sulphides which produce flocculating substances; it is remarkable that graphite in mixtures oxidises more slowly when the particles are small than when they are large. The surface-factor principle is applicable to the clay-grog aggregates, the best results being obtained when a flaked graphite is arranged tangentially to the surface, but suitable bond clay and clay-graphite mixtures are not controlled so much by proportions or chemical formulæ as by undefined standards of refractoriness and binding power obtained by trial and error. The colloidal theory of plasticity was discussed, also the separation of clay by electrical endosmose and the possible application of this to crucible manufacture.

A discussion followed in which Messrs. Thompson, Bailey, Bird, Cox, Jones, Grounds and Webb took part, mainly on the general theory of the coagulation of clay and its binding power.

The annual meeting of this section will be held in Cardiff on March 2. Capt. Hugh Vivian has been nominated chairman and Mr. W. R. Bird vice-chairman for next session. Prof. C. M. Thompson, the retiring chairman, will give an address on "Rare Earths in Relation to Incandescent Lighting."

YORKSHIRE SECTION

The third meeting of the Session was held on January 29, Dr. L. L. Lloyd in the chair.

The first paper read was by Mr. G. W. Douglas on the Separation of Propionic Acid from Pyroligneous Acid. It was a critical examination of the methods hitherto proposed for estimating small amounts of this acid in acetic acid. These were based on differences in the rate of distillation, differences in volatility in a current of steam, solubility of their salts or fractional precipitation from solution, and all were found to be unreliable for the purpose and only moderately satisfactory when large proportions were present. Examination, too, of the basic salts did not give the desired results. In the course of a short discussion the possibility of a physico-chemical method, such as conductivity, was emphasised.

"The Colour Measurement of Brown Solutions" by Professor H. R. Proctor, was read by Mr. F. C. Thompson. The simple method devised by the author is likely to prove of considerable service in the tanning industry, depending as it does on an arithmetical relationship and not as is usual on a logarithmic one. It gets over the difficulty, too, of matching colours by a synthetic method, as these differ in differing lights, whereas by a spectroscopic one a match can be obtained which does not differ in different conditions of lighting, unless, of course, a chemical change is occurring.

Brown solutions are easy to deal with as the absorption spectrum measurements give a smooth regular curve and it is only necessary to measure 3 or 4 points on it. With ordinary analytical strengths, the relationship $c \times t = \text{const.}$ is exact where c is concentration, and t depth, and it is only necessary to have a standard.

This is supplied by a 20 per cent. iron alum solution, which, however, cannot be diluted, but the tannin extract can, as within limits dilution does not affect the colour. Half light is used and the depth of a tannin solution compared with that of the iron alum at three lines in the spectrum gives the colour measurement. The prism has been found not to be required and it is only necessary to use red and green glasses, but for the blue a cuprammonium solution is used. This makes for still further simplification. When the colour value given by the relation between the depth of iron solution and the depth of extract is greater than unity, the colour is darker than the standard. The apparatus was exhibited. For tannin work it is better and easier to use than the Lovibond Tintometer.

LONDON SECTION

A paper on "The Estimation of Fat in Casein" was read by G. T. Bray and F. Major, B.Sc., at the meeting held on February 5 (*cf. Chem. & Ind.*, Feb. 9, p. 127).

In this paper the authors state that a sample of Indian casein in which they had determined the percentage of fat by the Werner-Schmidt method to be 7·4 had also been examined by Gangolli and Meldrum in India, who found 0·24 per cent., using the Soxhlet ether-extraction method and subsequently confirmed their figure by the use of a new "absolute method" which they had devised (*Dept. Industries, Bombay Pres.*, 1921, *Bull.* No. 4; this J., 1921, **40**, 746 A.) The difference being of such a fundamental nature the published methods for the estimation of fat in casein were subjected to a comprehensive review at the Imperial Institute with the result that it was shown that the Werner-Schmidt method gives the most satisfactory results. Experiments were described showing that the fat is not completely extracted by ether from dry casein, using a Soxhlet extraction apparatus, even after a period of thirty-one hours. Concordant results were not readily obtained by the Rose-Gottlieb method; the results were low compared with those found by the Werner-Schmidt method, and in the former method it was often difficult to get the casein to dissolve satisfactorily in the dilute ammonia, even on warming.

The Werner-Schmidt method was found to give concordant and most reliable results. According to the details recommended by the authors, the casein is dissolved by warming with 4 parts of hydrochloric acid (sp. gr. 1·16) and 2 parts of water for forty minutes on a boiling water-bath prior to extraction with ether, the ether extract being extracted with petrol to isolate the fat. The contention that the fat obtained by this method contains products of the hydrolysis of the casein and that this method therefore gives results that are too high was shown to be wrong. Experiments carried out by the authors indicated that more favourable conditions for the hydrolysis of the casein do not influence the percentage of fat obtained and also that the petrol-soluble matter (fat) obtained does not contain sufficient nitrogenous hydrolytic products to vitiate the accuracy of the estimation. The method recommended by Gangolli and Meldrum was shown to be thoroughly unreliable and to give low and inaccurate results, as by this method the fat is not completely extracted. The casein does not dissolve satisfactorily in the caustic-soda solution used, and it was found that the whole of the fat is not removed completely by the one extraction with ether, which, according to the details of the method, is stated to be sufficient. The authors concluded by stating that their experiments showed that the Werner-Schmidt method was the best and most reliable method for the estimation of fat in casein and that the percentage of fat (7·4) found by them in a sample of Indian casein and considered by Gangolli and Meldrum to be inaccurate is correct.

BIRMINGHAM AND MIDLAND SECTION

In the continuation of the discussion on Fuel Problems held on February 6, Mr. E. C. Evans said that these problems had to be attacked from a national standpoint. The production of coke of uniform composition from different types of coal was equally important to the three great industries most dependent on fuel, viz., the iron and steel, gas, and mining industries. Mr. E. R. Sutcliffe and himself had shown that by utilising finely divided coal, a coke could be produced which, in chemical composition and physical characteristics, was much better than anything which had been adopted in the past; such a coke promised revolutionary economies in the production of pig iron. The production of smokeless fuel was primarily a question for the gas industry. Recent developments allowed of the production of such a fuel with, at the same time, a high yield of gas. With reference to the problems of the mining industry, many of the waste fuels of the country could be readily converted into a high-class industrial or domestic fuel by blending coals from different fields. The solution of many of the problems of fuel utilisation depended upon a national aspect of the question being taken, and on co-ordination of the research work in various districts.

Various aspects of coal firing was discussed by Mr. R. E. Keeling, who said that firing with powdered coal was new in this country. Two systems, the "central" and "unit" systems, were used; of these the "central" system, largely adopted in the United States, was responsible for the objection in this country to the use of powdered coal because of its liability to cause explosions. In the "unit" system coal was powdered as required. By using powdered fuel, the fuel consumption could be reduced by from 30 to 50 per cent., and low-grade coal costing from 5s. to 6s. per ton could be used, realising a saving in fuel of from 60 to 70 per cent. With "unit" plants working in the Birmingham district great economies had been obtained.

Dr. W. E. Smith advocated that gas undertakings should produce smokeless free-burning fuels instead of coke. No great headway would be made in the production of smokeless fuel until gas works produced solid fuel (free burning and smokeless) as well as gaseous fuel. Only in this way would the ideal solid fuel be produced at a reasonable price. Progress was being retarded owing to the patent position, but there was nothing in this that should inconvenience honest workers. Surprise was expressed at the action taken by one W.A.B. in raising the CO "bogey" in the correspondence columns of *The Times*: the nett result had been an increase in the number of people who preferred the "gas way" to end their lives than the more generally accepted ways. It was fortunate that the gas industry was well established, otherwise when it was found that wireless enthusiasts were courting dangers of explosions and fires by earthing their equipment to gas pipes, W.A.B. might demand an enquiry—by unbiassed men of the highest scientific attainments—to advise the Board of Trade as to whether it was safe for gas to be distributed in houses, inhabited by the poor, in iron pipes. Although it was important to increase the efficiency of production of fuel it was still more important to increase the efficiency of the utilisation of fuel. This had been done in connexion with lighting and gas fires, but much more required to be done in connexion with industrial heating furnaces.

SOUTH WALES SECTION

The last meeting was held at the Technical College, Swansea, on February 9, and Mr. F. G. Bloomer, F.I.C., presided, in the unavoidable absence, through illness, of Capt. Hugh Vivian.

Mr. H. B. Hitch read a paper on "Stainless Steel," which was illustrated with many lantern slides of micrographs and diagrams. As is well known, so-called "stainless" steel contains about 14 per cent. of chromium and 0·3 per cent. of carbon, and has the remarkable property of resisting atmospheric and subaqueous corrosion when the surface has not been deformed by cold working, such as drawing into wire. Some pieces of this steel were shown which were perfectly bright after six months under sea-water, as well as steam-valve seatings which after several months' use exhibited no signs of staining. The lecturer went fully into the properties and heat-treatment of various similar steels, containing larger and smaller percentages of chromium, and also touched upon stainless iron; an iron containing, per cent., chromium 11·7, nickel 0·57, manganese 0·12, silicon 0·08, and carbon 0·07, had excellent properties. A short discussion followed, in which Prof. C. A. Edwards advocated co-operation between chemists and metallurgists.

CHEMICAL ENGINEERING GROUP

The meeting held at the Chemical Industry Club, on February 9, was devoted to a discussion on "Leaching and Evaporating." Mr. J. A. Reavell (chairman of the Group) was in the chair.

Professor F. G. Donnan opened the discussion by giving a series of elementary formulæ which he had prepared as the result of a visit made during the war to Chile, where he investigated the working of six or seven nitrate factories. They were elementary mill formulæ, designed to improve the efficiency of the factories in question, which was very low, namely, between 50 and 60 per cent., instead of the 90 per cent. or more which ought to have been obtained.

The chairman then showed a number of lantern slides of modern leaching plants of the open and closed types for extracting tan from barks or wood. He drew special attention to a plant which was designed by Sir John Thornycroft during the war, for treating sugar, and was described as one of the best systems of leaching that had ever been designed. This apparatus gave a perfect counter-current effect, and was of the greatest use during the war, as the leaching systems for sugar, although very complete, were not as satisfactory as they could have been. Another form of leaching apparatus, which had recently been put to work in India, was a gas-agitation tanning extraction process. Indian barks differed from other barks, in that the fibre tended to block up the mesh or the perforated copper bottom of the apparatus; this was avoided by replacing the air for circulating by gas taken from the engines driving the mill, the gas engines using charcoal as fuel. Kauwa bark, which was used in this particular case, was found to contain 35 per cent. of tan, and also 40 per cent. of pure calcium oxalate. This oxalate was a by-product of the tan factory, and it might eventually be found that the tan factory would be a by-product of the calcium oxalate. It was found that it was difficult to get the charcoal ovoids made from the spent bark to burn properly, and after examination in the laboratory the surprising discovery was made that the Kauwa bark contained this large percentage of calcium oxalate.

Dr. Gordon Parker asked Mr. Reavell what objection he had to the press leaching system in preference to the battery system for bark or tanning material. The press leaching system saved steam, and he was surprised that Mr. Reavell in his plant should use a pumping system, which he considered as somewhat antiquated. One point about the Thornycroft plant was that it would help to save the cost of the leaking doors of the ordinary apparatus. If any material got around the edges of the door the average workmen just jammed the door in order to close it and did not trouble to remove the material; as a result even the best doors soon leaked.

Mr. P. Parrish said the question of leaching had got to be looked at from at least three points of view. He had had a good deal of experience in connexion with the calcining of cupreous pyrites, which was a totally different proposition from the one which Professor Donnan had dealt with. Professor Donnan's proposition was essentially the same as that which arose in preparing sodium sulphide, but even in that case there was a preliminary operation and all sorts of factors operating, which either assisted or retarded the efficiency of the leaching. In much the same way the efficiency of the extraction of copper was either assisted or retarded by the efficiency of calcination. Then there was a third case, such as that which arose in extracting ferrocyanides or spent oxide. Two years ago he visited a country somewhat allied to Chile, and had had a similar difficulty to that experienced by Professor Donnan, in that those responsible for the works had no efficiency figures. The result was that it had been necessary to determine, first of all, the overall efficiency of the extraction by leaching, which he found did not exceed 30 per cent. Then he had to determine in a very short time the source of this inefficiency, and he found that it was due primarily to the fact that they were using an inordinate quantity of lime in relation to the Prussian blue content of the spent oxide, and polysulphides were being formed which converted the ferrocyanides into sulphocyanides, thus causing loss. The leaching was by no means efficient, but even that did not account for the low overall efficiency of 30 per cent. In order to obtain satisfactory leaching with pyrites a special screening test must be applied to every variety of cupreous pyrites, and the physical condition must be correlated to the physical characteristics of the material. The same thing applied to spent oxides used at gas works. Spent oxide which was of a granular character after purification by hydrogen sulphide and hydrocyanic acid was reasonably porous and admitted of satisfactory leaching but if they took bog ores from Holland or Belgium, or even the German Lux, which contained alumina and also iron in a peculiar colloidal form, it was very difficult indeed to leach that material and to get it absolutely free from Prussian blue. He did not think there was any great difficulty in working to the 90 per cent. efficiency which Professor Donnan had indicated, but there was a tendency in a number of works throughout the country either to discard the mother liquor or to leave the material in a wet condition before it was discharged from the lixiviators, and a great deal of loss arose there, because after the first wash there was a highly concentrated solution that was occluded in the pores of the mass to be subsequently leached. All sorts of trouble arose by reason of the fact that the mass which was to be leached was not strained or pumped sufficiently well.

Dr. W. R. Ormandy referred to the extraction of soluble material from vegetable matter by cataphoresis, which had been worked out by Count Schwerin in Germany, and had been applied on a large scale for the production of sugar from sugar beet. A much purer sugar solution could be obtained in a concentrated form in that manner, but the actual cost of the apparatus and electric current was too great to render it possible as a commercial operation, whereas the cost of ordinary leaching was comparatively small after allowing for the first cost of the plant.

Mr. A. Reid criticised the Thornycroft leaching apparatus on the score that it seemed to be expensive, especially where a large volume of material had to be dealt with.

Prof. J. W. Hinchley thought that the formulæ given by Professor Donnan were by no means so unnecessary for some works in this country as might be imagined. His experience suggested that the efficiency in works in this country could be considerably improved by more careful methods of control. He regarded the Thornycroft plant as an extremely clever one, but it did not follow that the form shown on the screen was that in which it would be applied for every class of material. Such a high figure of efficiency as 90 to 95 per cent. might be purchased at too great a cost, and the real point to be borne in mind was ways and means of increasing efficiency without increasing cost.

Mr. J. A. Reavell, in replying, said that pumping was adopted in his firm's plant because it enabled the exact temperature at any time to be obtained; with the press leaching system that was not possible. The cost of the Thornycroft apparatus could, obviously, be considerably reduced by building it of wood. Prof. Donnan also briefly replied.

* * *

Prof. U. Pratalongo, of the Royal Higher School of Agriculture, Milan, has been awarded the Cagnola Prize of 2500 lire and a Gold Medal, by the Lombard Institute of Science and Letters for his paper on "The Importance of Catalysis and Enzymes in General, Biological and Applied Chemistry."

From Germany the following deaths are announced:—Prof. A. Fischer, director of the department of applied chemistry of the Technical *Hochschule*, Aachen; Dr. A. Schaitberger, chemist to the Siemens-Schuckertwerke; Dr. J. Vogel, director of the Bacteriological Institute of the University of Leipzig; Prof. K. E. Bessel, formerly director of the Physikalisch-Technische Reichsanstalt.

MEETINGS OF OTHER SOCIETIES

SOCIETY OF PUBLIC ANALYSTS

The Annual General Meeting was held in the Chemical Society's Rooms, Burlington House, on February 7, when the President, Mr. P. A. Ellis Richards, delivered his annual address. The following were elected as Officers and Council for the ensuing year :—*President :* P. A. Ellis Richards. *Past Presidents :* Leonard Archbutt, A. Chaston Chapman, Bernard Dyer, Otto Hehner, Samuel Rideal, Alfred Smetham, E. W. Voelcker, J. A. Voelcker. *Vice-Presidents :* F. W. F. Arnaud, F. H. Carr, G. W. Monier-Williams. *Hon. Treasurer :* Edward Hinks. *Hon. Secretary :* E. R. Bolton. *Assist. Hon. Sec. :* R. G. Pelly. *Other Members of Council :* H. Ballantyne, S. F. Burford, S. Elliott, B. S. Evans, E. M. Hawkins, Harri Heap, H. F. E. Hulton, Andrew More, A. E. Parkes, W. R. Schoeller, G. R. Thompson, and J. F. Tocher.

Of the two papers read, the first, entitled "Titanium in Nile Silt," was by Mr. E. Griffiths-Jones, who has examined silts from various parts of the Nile and determined the titanium by a colorimetric method after freeing the sample from silica. Amounts varying from 1·3 to 2·55 per cent. of titanium oxide on the dried silt were found, but an examination of Egyptian straw, a likely source of titanium, only showed 0·4 per cent. of titanium oxide on the ash.

"Notes on the Examination of Preserved Meats, etc." were read by Mr. Osman Jones, who stated that the presence of a trace of zinc chloride in the tin container (which sometimes arises through the use of this salt as a soldering flux) caused a more rapid absorption of tin by the food contents, and that the use of a sealing fluid containing a high boiling-point solvent gave the food material a disagreeable flavour. Methods for detecting such a solvent were given. The absorption of tin by the meat contents of a can was found to be greatest at the time of processing and almost to cease after about four months. The author also mentioned a test for agar in the presence of gelatin :—A dilute solution of iodine in potassium iodide gives a crimson colour with agar, whereas with gelatin an orange coloured precipitate is produced.

SIR JOHN CASS TECHNICAL INSTITUTE

The Annual Prize Distribution was held at the Sir John Cass Technical Institute on January 31, when the prizes and certificates were distributed by Sir Thomas Holland, K.C.S.I., K.C.I.E., F.R.S., Rector of the Imperial College of Science and Technology. The Chairman of the Governing Body, the Rev. J. F. Marr, in summarising the work of the Institute during the past session, said that during this period a total of 1,073 students had been in attendance, the highest figure yet attained. The year had not been an easy one, as financial considerations were still conspicuously in the foreground. Although the need of economy was realised, the best objectives of education were being, to some extent, lost sight of. The needs of technical education could not be satisfied, and progress would never be obtained without mutual trust and confidence between the public authorities and those administering the funds placed at their disposal and without a full belief in the national value of technical education. Despite the restricted accommodation in the Science Departments, 31 students had been engaged in research work and five papers had been published, bringing the total number of original investigations issued from the Institute to 120. Twenty-five students had been successful at University of London Examinations, six having gained the B.Sc. Degree with Honours in Chemistry. For the second year in succession a student of the Metallurgy Department had been awarded the First Prize (Silver Medal) in the City and Guilds of London Institute examination in non-ferrous metallurgy.

In an address on "Humanism in Technical Education," Sir Thomas Holland referred to the divergence of opinion and the clash of ideals that have long existed with regard to education, and after giving several examples of opposing views he stated that it was impossible to stress any one truth without apparently being unfair to some other truth. Did this apply to the education of the technologist ? He must become an expert in the workshop, but in addition he had duties as a citizen and must face relations with other human beings. In order to be appreciated he must understand and be understood by others, or in other words, he wants the "humanities." Scientists were liable to succumb to that form of pedantry which in classics exchanged humanism for grammar and rhetoric. We must not claim that science could give a mental training as good, when really we mean as bad, as that afforded by classics. Unfortunately this was the attitude assumed by some teachers of science who had yet to learn that the stimulation of curiosity would give human interest to a student's work, and was a large part of the teacher's task. Sir Thomas Holland concluded by stating that he would like to try the experiment of covering the syllabus of, say, metallurgy or chemistry by lectures on biography alone. He felt sure that students could be trusted to fill in the historical framework on their own account and to find out technical details for themselves, and whether they succeeded wholly or partially, they would be better men for having made an effort inspired by a natural and healthy curiosity.

Dr. Charles A. Keane, the Principal of the Institute, thanked Sir Thomas Holland for his inspiring address and gave a brief account of the activities and progress of the Institute.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

The newly-created "Fuel Group" held a meeting in Paris on January 31 at which Monsieur A. Kling, director of the Municipal Laboratory, read a paper entitled "What is Coal?"

After considering the treatment of coal at the pit-head, attention was devoted to the extraction of the valuable constituents of the coal and the utilisation of the residue as a fuel. A historical summary was given of researches on the origin and composition of coal, and it was pointed out that further investigation was required of the action of certain basic organic solvents, taking into account the benzenoid structure of the constituents of coal. An account was given of the work of Bergius, who has treated pulverised coal suspended in a hydrocarbon with hydrogen under a pressure of 230 atmospheres at a temperature of 430° C., and has transformed the coal, exception being made of the ash, entirely into liquid hydrocarbons of unknown constitution, but giving, on distillation, 30 per cent. of light fuel oils, 30 per cent. of Diesel-engine oils, 30 per cent. of fuel oil or binder for briquettes, and 10 per cent. of gaseous hydrocarbons. Monsieur Kling put forward the hypothesis that the chief constituent of coal consisted of a molecule formed by a substituted benzenoid or hydrobenzenoid nucleus, the molecule being capable of condensation by reactions similar to those leading to the formation of proteins from amino-acids.

At present it was considered that the main body of the coal mass had resulted from splitting of the lignocellulose molecule, followed by the destruction of the cellulose and finally the transformation of the lignone. In addition, the main constituent was mixed with products which were due to the breaking down of the pecto-, muco-, adipo-, and cuto-celluloses and represented the bituminous constituents of coal; the nitrogenous constituents were derived from degration production of plant proteins. In conclusion, Monsieur Kling reviewed the work of research organisations devoted to the study of fuels in England, Germany and France, and outlined an interesting programme of research on coal from the standpoints of chemistry, mining, gas production, geology, commerce and industry. This programme is to be considered by the French Coalmines Committee and the Société de Chimie Industrielle.

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held on February 8, Sir William Pearce presiding in the absence of the chairman, Sir Max Muspratt, Bart., who was unable to attend owing to slight indisposition. The following letter was received from Dr. Carpenter intimating his acceptance of the position of Honorary Vice-President of the Association for life:—

Dear Mr. Woolcock,—The share I took in the formation of the Association will always be regarded by me with a certain satisfaction, for I believe I not only contributed thereby to the welfare of a great industry, but also to the well-being of the Nation it serves.

The friendships I have made in the Association have repaid many times over the small services I was privileged to give.

The honour your Council proposes was quite unlooked for, and in accepting it I can only say that I regard it as the greatest compliment British industry could bestow, and as such I shall ever value it.—Believe me, Yours very truly (Sgd.) Charles Carpenter.

Messrs. Oliver Wilkins & Co., Ltd., were admitted to membership of the Association.

The General Manager reported that over 30,000 sq. ft. of space had been applied for in the Chemical Section of the British Empire Exhibition, 1924. The question of a Scientific Exhibit in the Chemical Section was considered and the Council agreed to contribute a sum of £1000 towards the expenses in connexion therewith.

The Society's *Journal* was discussed and recommended to members as their advertising medium.

It was agreed to oppose the Oakham Gas and Electricity Bill, which seeks to obtain powers to make, produce, work up, convert, store, sell and deal in any products and materials directly and indirectly arising from or used in the generation, transformation or distribution of electricity and any by-products of coal, etc.

A letter from the Chief Inspector of Factories regarding the form of register to be kept in connexion with the inspection of bleaching powder chambers under the Factory and Workshop Act—Chemical Regulations—was considered.

The Council re-appointed Mr. W. J. U. Woolcock, C.B.E., as General Manager of the Association for a further period of five years.

Trade with Occupied Germany—Warning to Traders

The Board of Trade desires to draw the attention of British traders to the fact that, in virtue of recent measures taken by the French and Belgian Governments, the control of the importation and exportation of goods by firms situate or established both in the former Occupied Territory of Germany and the Ruhr, and the power of fixing the conditions under which import and export licences may be granted, is now vested in a Special Allied Committee. The German Government has, however, refused to recognise the validity of any licences issued by the Allied authorities in the Occupied Territory since January 23 for importation into, or exportation from the Ruhr or former Occupied Territory. Goods so licensed should, therefore, not be forwarded by any route which involves transit through German territory not occupied by the Allies.

MR. ARTHUR CAREY

Many of our members—more particularly those of the Liverpool Section—will learn with deep regret that for reasons of health Mr. Arthur Carey has felt it necessary to relinquish his position as District Manager of the Widnes and St. Helens Works of the United Alkali Co., Ltd. His father, the late Mr. Eustace Carey, played a very prominent part in founding the Society—he was President in 1906-1907—and Arthur Carey from the beginning of his career followed his father's lead and by papers and other means did all he could to promote its activities and aims. Recognition of his efforts led to his election to the Committee and later to the Chairmanship of the Section.

After an education started in London and completed with distinction at University College, Liverpool, he entered the service of the United Alkali Co., Ltd., in 1891, as assistant to the late Dr. Hurter. In 1892, when Dr. Hurter took command of the newly completed central laboratory, Mr. Carey was appointed Chief Chemist of the Company's Gaskell Deacon Works, and his efforts there are well illustrated in the *Journal* of the Society and in the Patent List, in problems relating to hydrochloric-acid condensation; improvements in the Deacon process; sodium hypochlorite manufacture, etc.

In 1897 he was transferred, again as Chief Chemist, to the Company's Sullivan Works, where developments along new lines necessitated skilled supervision and advice. Here, in addition to improving manufacture, he was largely responsible for instituting industries new to this country; more particularly as regards the manufacture of nitrochlorbenzene derivatives. This pioneer work proved of great importance in the war, inasmuch as a further step led to the production of picric acid from benzol instead of from the hitherto usual and practically unobtainable phenol. This development has played a large part in the founding of the dyestuffs industry in this country—how great such part may prove only the future can tell. In 1914 Mr. Carey succeeded the late Mr. Joseph Morrison as District Manager in the Widnes area. The advent of the war a few months after his appointment added materially to his work and responsibility, but his wide knowledge and practical experience enabled him to deal with the numerous new problems confronting the industry during that period.

Public work connected with education, pensions and unemployment also claimed not a small share of his time, and despite a visible failing in health he insisted on attending to his duties and was never known to spare himself. It is our sincere wish that the present period of rest will lead to such restoration of health as will enable him to do further work for the industry to which he has devoted his life's energies.

CORRESPONDENCE

ARSENIC IN MALT

Sir,—In the report of the meeting of the Nottingham Section of the Society of Chemical Industry, published in your issue of February 9 (of which I was not given the opportunity of seeing the proof in time for correction), my remarks are seriously misrepresented.

I said that (as is well known) malts formerly contained appreciable traces of arsenic, but I did not say that "this often gave rise to beer having a percentage above the legal limit," as this is not the case. For absolute safety to the consumer the legal limit was fixed by the Royal Commission at the extremely low figure of one hundredth of a grain to the gallon of beer (*i.e.*, only one part in seven millions). But present-day beers scarcely ever contain even half that amount—are, indeed, to all intents free from arsenic.—I am, Sir, etc.,

"R.T.M.H." REPLIES TO "EYE-WITNESS"

Sir,—May I thank kind "Eye-Witness," who for my "moral state" feels sore, for warning me with such distress not to write verses any more. He knows, too well, the verse-fiend's fate; he clearly trod the same dark track, and, like the beery reprobate who sees youth, drunken, go to wrack and bids him halt ere he should be as blear and beery, so this seer attempts to give me pause. But he is much too late I greatly fear. My "youth" (assumed extreme) is far behind, and further, year by year, becomes. In time no doubt I'll mar the virgin sheet with prose. But this I promise, while I keep my brains, "verses which seems" and like remarks I'll miss, and try to write good grammar. R. T. M. H——s.

PROFESSOR ARMSTRONG AND THE SMOKE ABATEMENT COMMITTEE

Sir,—Having read Prof. J. B. Cohen's letter on the above subject in your issue of February 2 last, as well as Prof. H. E. Armstrong's recent strictures upon the Committee and its Report, I desire to express my general agreement with the latter's view of the matter, which (so far as I am able to judge) is widely held in industrial and technical circles.

The composition of the Committee did not inspire much confidence in its ability to deal with the subject comprehensively on really practical lines; and its Report is, to me, a singularly disappointing production, lacking in constructive thought and outlook. It would be interesting to know how many of its members were familiar from first-hand knowledge with the chemistry of coal, its gasification and combustion, with industrial heating operations, and with the wide range of practice comprised in modern fuel technology. For, unless the majority of them had such knowledge at first hand, how (it may be asked) could they possibly arrive at a sound judgment upon the evidence submitted by the 130 witnesses about how to abate smoke, or what was the use of them touring industrial centres "in order to inquire on the spot into the cause of the smoke and other nuisance from noxious fumes" or to hear complaints, etc. ?

What was wanted on the Committee was not so much the experience (valuable as it was) of people who had measured the evils of smoke and fog—which, indeed, are now so universally admitted as to be no longer in dispute—as of those who know how boilers can be stoked so as to give efficient combustion with a minimum of smoke, and could advise as to the most practical steps which could be adopted for the mitigation of industrial smoke generally.

It is, of course, high time that something really practical were done both to deal with the smoke nuisance and to promote fuel economy in industrial operations; but the subject is beset with complications and difficulties of all kinds, and amateurish incursions into it are to be deprecated. During the past three years the Federation of British Industries has established a Technical Sub-Committee which is doing good pioneering work in advising manufacturers as to economising in coal and, incidentally also, smoke abatement; but although this is a good beginning on right lines, it has so far only touched the fringe of the problem and needs to be extended. It is chiefly to such well-directed efforts, rather than to Government Committees and their Reports, that in future we must look for enlightenment and progress.

Seeing, however, that coal and its combustion is a chemical matter, why should not the Society of Chemical Industry set up a committee to consider the subject of smoke abatement and on what lines it may best be promoted by both education and legislation ? From such a body we might get something that would "cut ice" and be worthy of serious consideration. Meanwhile, chemists may feel grateful that Prof. Armstrong has called attention so incisively to the present unsatisfactory position of the matter.—I am, Sir, etc.,

William A. Bone

London, February 10, 1923.

EXPLOSIVES IN LIQUID AIR RECTIFICATION PLANT

Dear Sir,—In your editorial of February 9 you were good enough to refer to a paper read by me on the above subject before the London Section of the Society of Chemical Industry, and already published in the *Journal* of the Society. In the course of your remarks you wrote that "various explanations were suggested as to the possible origin of these" explosions. I feel that this phrase might quite inadvertently convey to some of your readers the impression that there was still some doubt as to the essential facts, and in view of the importance of the question to certain industries I write to emphasise the facts, firstly, that these explosions are caused by an accumulation of acetylene or other acetylenic hydrocarbons in the liquid oxygen bath of the rectifying column, and secondly, that these compounds are invariably formed if through lack of adequate cooling the lubricating oil in the air compressor attains too high a temperature. The only question as to which uncertainty still exists is, in my opinion, the exact nature of the impulse which leads to detonation of the highly explosive contents, so produced, of the liquid oxygen bath.

In view of these facts the necessity, firstly, for keeping cool an oil-lubricated air compressor feeding a liquid air plant, and secondly, for the most stringent precautions to avoid any possibility of acetylene entering the compressor from without, can not be too strongly insisted on or too widely known. Weight for weight a mixture of solid acetylene and liquid oxygen is an explosive very much more powerful than dynamite.—I am, Sir, etc.,

Ernest Fyleman

Sutton, Surrey.
Feb. 10, 1923

PERSONALIA

Mr. E. R. Bolton has been appointed to represent the Society of Public Analysts on the Federal Council for Pure and Applied Chemistry in place of Dr. Rideal.

* * *

With great regret we announce the death, at the age of 78, of Prof. W. K. von Röntgen, the discoverer of X-rays. The discovery that a Crookes vacuum tube emitted rays that would penetrate solid bodies was made almost simultaneously by Professors Lenard and Röntgen, and for this they were jointly awarded the Rumford Medal of the Royal Society in 1896. Not only has the application of the discovery proved of incalculable value in medicine and surgery, but in the hands of experimenters such as Moseley and Bragg it has been the means of throwing new light on the structure of the atom. Röntgen, who had been professor of experimental physics and director of the Physical Institute in Munich for many years until his resignation in 1919, and was an honorary member of the Royal Institution of Great Britain, was awarded the Nobel Prize for physics in 1901. His other physical work is not well known, but his method of determining the wave-length of shrill musical notes has been used in investigating the molecular structure of argon and helium.

NEWS AND NOTES

BRITISH INDIA

Glue-making in Madras

Germany formerly imported large quantities of tannery waste from the Madras Presidency, presumably for the manufacture of glue. During the war, the closure of Continental markets led to the accumulation of large quantities of fleshings, and the Madras Department of Industries attempted to utilise the material locally for making glue. The experiment was not completely successful, as the problem of getting the glue solutions to set in the high temperatures of Madras still remained unsolved. In 1917 a method of treating the fleshings was finally evolved which yielded a glue that set under the most adverse climatic conditions, and a glue factory was afterwards established in Madras. According to the *Indian Trade Journal*, the factory was closed for some time owing to trade depression, but re-opened early in 1921. Although the experimental stage is not yet passed, the factory has a capacity of 80 tons of glue a month, but at present is producing 3—4 t. per month from about 15 t. of raw materials. Import statistics reveal that the Indian demand for glue is larger than has been supposed; in the fiscal year 1920-21, 52 t. of glue was imported into Madras alone.

FRANCE

National Office for Scientific and Industrial Research and Inventions

By a recent law, this Office, which is situated at Bellevue and is directed by Senator J. Le Breton, was given financial and administrative autonomy. A decree has now been issued regulating the constitution and functions of this new organisation devoted to research and inventions. The Office is to be controlled by a National Council and an Administrative Council, the latter being appointed by the Minister of Public Instruction and including many of the best-known names of French science and industry. Chemistry is represented by Prof. Charles Moureu, member of the Institute, professor at the Collège de France, and president of the French Chemical Society.

GERMANY

Cultivation of Potatoes for Starch

Prof. E. Parow, head of the Berlin Research Institute for Starch Manufacture and Potato Drying, has written an interesting article in the *Zeitschrift für Spiritus-industrie* on the culture of varieties of potato rich in starch and possessing large starch granules. He shows by means of photographs the great variations in the size of granules from different sources, the range being from 0·002 to 0·087 mm. It is known that a potato with large starch granules will yield not only the greatest quantity but also the best quality of starch flour, and the content of large granules is important in such technical operations as drying and distilling, as well as from the standpoints of food-value, taste, and keeping quality. Such investigations as Prof. Parow has started are likely to be of economic importance.

GENERAL

Al Rāzi (Rhases) as a Chemist

The fame of Al Rāzī as a physician has tended to overshadow his achievements in other directions, especially in chemistry. Yet several chemical works of his are known and two, the "Book of Quotations" and an "Introductory Book to Chemistry," have been partially translated by Stapleton. Prof. J. Ruska, writing in the *Zeitschrift für angewandte Chemie* (1922, 35, 719—721), describes his discovery among the Arabic stone manuscripts in the Göttingen Library of a complete and systematic text-book of ancient chemistry which is undoubtedly the "Kitab sirr alassar" mentioned by Al-Nadim in 987. In the introduction to this work Al Rāzī says: "This book is divided into three sections which deal respectively with the knowledge of matter, of apparatus and of operations. Matter may be divided into three kinds—animal, vegetable and mineral. There are six varieties of mineral matter πνευματα, volatile substances, and σωματα, metals, rocks, vitriols, boraxes, and salts. The volatile substances are quicksilver, salammoniac, sulphur and zarruch (arsenic sulphides); there are 7 metals, 13 rocks, 5 vitriols, 6 boraxes and 11 salts." The author continues with a description of each substance and methods of distinguishing good and bad varieties together with processes for their preparation. The second part of the work describes apparatus for dealing with the metals and non-metals and the third part treats in seven sections of methods of changing one substance into another and includes recipes for the transmutation of base metals into gold and silver.

If this work is compared with various alchemical tracts of Greek origin of the same period, the fact that the former gives special prominence to experimental work, whereas the latter are chiefly concerned with mystical philosophical speculation, shows that chemistry had made greater strides among the Arabians and Persians during the eighth and ninth centuries than among the Greeks. Al Rāzī was evidently one of an advanced school of chemists who could answer, as the result of many careful experiments, many of the questions that were still puzzling the Greeks. Thus, in another book dealing with medicinal substances he describes the colour, taste, smell and method of powdering, burning, washing and subliming substances; the methods of preserving and preparing medicines and the duration of their action, their constitution and suitable substitutes were also known to him. This book also contains a dictionary of medicines in the Greek, Syrian, Persian, Indian and Arabic languages.

Prof. Ruska discusses the possible sources of Al Rāzī's chemical knowledge at some length, and comes to the conclusion that they are chiefly Persian. The Greeks at that time knew nothing of salammoniac, whereas this substance plays an important part in Al Rāzī's chemical theory, being one of the foundations of the theory of the transmutation of metals and also playing an important part in medicine. He had no knowledge of its formation from camel dung, as his supplies were obtained from Khorasan and Bokhara under the name of Nūsādir, a word which is probably of Bactrian origin. Most of the names of rocks, earths, artificial products and apparatus found in his books are of Persian origin, and in many cases were unknown to the Arabians and Syrians. They show by the middle Persian formation of the words that they were probably derived from the medical school at Gondeschapur.

Partition of Austro-Hungarian Industries

The distribution among the Succession States of the chemical and mining industries of the former Austro-Hungarian Empire is shown by the following figures of production before and after the war:—

		Former Austria-Hungary		Succession States			
				Austria	Czecho-slovakia	Hungary	Yugo-slavia
Paper	Metric tons	345,652	63,550	187,000	180,000	2,500	16,000
Sulphuric acid	,,	70,000*		10,000	36,000	12,000	9,000
Hydrochloric acid	,,	—	—	2,500	48,000	1,000	500
Soda†	,,	—	—	40,000	30,000	—	30,000
Caustic soda	,,	36,000	3,600*	—	12,000	—	7,200
Carbide, cyanamide†	,,	—	—	15,000	40,000	2,000	185,000

* Output in 1913. † Capacity.

It will be seen that the paper industry is divided almost equally between Austria and Czechoslovakia, that the latter country is responsible for the bulk of the production of sulphuric acid, hydrochloric acid, and matches, and that Yugoslavia produces nearly four times as much carbide and cyanamide as Austria and Czechoslavia combined. Austria, however, has retained important deposits of graphite and magnesite, but has lost half the State salt mines to Galicia, and those in the Bukowina to Rumania. On a pre-war basis Austria could produce about 100,000 t. of salt in excess of her requirements; Czechoslovakia has to import it although she received about one-fifth of the salt resources of Hungary; the remainder of the salt deposits was allotted to Rumania. The bulk of the production of pig iron is centred in Czechoslovakia, although important branches of the iron-working industries remain in Austria. In general, most of the large industries are now to be found in Czechoslovakia and the smaller in Austria. Hungary has lost 50 per cent. of its iron and metal industries, but only 15 per cent. of its engineering industry.

Mianin, a Chloramine Disinfectant

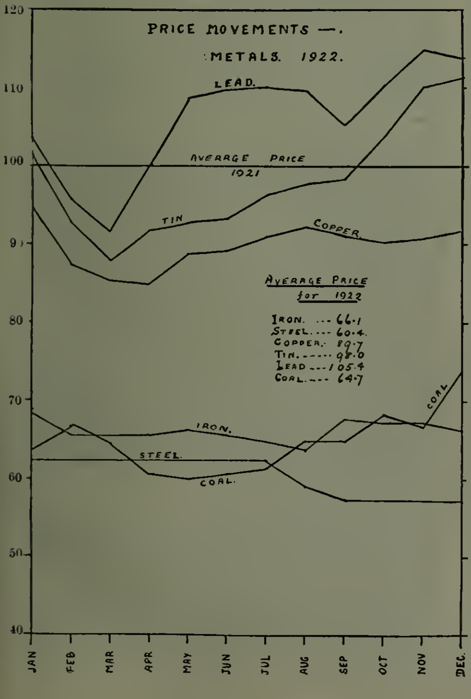
The disinfectant action of hypochlorous acid and its salts is well known and has been made use of in Dakin's solution, which can be prepared either from sodium or potassium carbonate and bleaching powder, or electrolytically, but is unstable. A similarly constituted solution, however, sold under the name of "Antiformin" remains unchanged for months. Bullier and Maquenne, in 1903 (D.R.P. 145,745), obtained a stable solid hypochlorite disinfectant by mixing 60 parts of bleaching powder and 40 parts of sodium sulphate, but this mixture has not achieved importance. A great advance was made in the discovery by Chattaway (in 1905) of the chloramines, compounds prepared by the action of hypochlorous acid on sulphonamides. Whilst certain of these chloramines are of little value owing to their insolubility (toluene-*p*-sulphondichloramide dissolved in chlorinated paraffin wax is known as "Clorcosan"), others, and in particular sodium toluene-*p*-sulphonchloramide, are of considerable practical importance. The last-named substance, having the formula CH_3— —$SO_2Na:NCl,3H_2O$, is prepared from toluene-*p*-sulphonamide and has been placed on the market by the Saccharinfabrik, A.-G. vorm. Fahlberg, List and Co., of Magdeburg-Südost, under the name of "Mianin." The same compound has been widely used in this country under the name or Chloramine T (*cf. Proc. Roy. Soc.*, 1916, [B], 89, 232, and this Journal, 1918, 37, 288 T), but the following notes on its properties, extracted from the *Chemiker-Zeitung* (1922, p. 1103) will be of interest. Mianin crystallises well and is easily soluble in water. It imparts a blue coloration to starch-iodide paper and can be directly titrated with potassium iodide and thiosulphate. It is an extremely powerful disinfectant, a 1:500,000 solution still acting with certainty. It is sold, for general disinfecting purposes, in tablets of 1gm., each containing 0·5 gm. of Mianin coloured with a yellow dyestuff, and also, as a deodorant, in the form of powder, containing 5 per cent. of the active substance. In aqueous solution Mianin is fatal, in 10 mins., to the following organisms at the dilutions stated:—Streptococci, 1:34,000; Diphtheria bacilli, 1:30,000; Pneumococci 1:22,000; Dysentery bacilli, 1:22,000; Typhus bacilli, 1:20,000; Coli bacilli, 1:18,000; Staphylococci, 1:16,000. It is practically odourless, and does not damage metallic objects or stain the finger nails. It may be used for disinfecting water, the taste of chlorine being no longer noticeable at a dilution of 1:20—25,000 and the disinfectant action persisting up to nearly 1:35,000. Mianin is non-poisonous and non-irritant, and can be taken internally in considerable quantity without harmful effects.

Naphthalene as a Wool Preservative

In a letter published in the *South African Journal of Industries* (Jan., 1923), Mr. A. A. Kloot, B.Sc., discusses the use of naphthalene for preserving wool. An inquiry into the cause of stains attributed to naphthalene gave the following results:—Coloured wools often contain as much as 0·5 per cent. of iron. Wool is sometimes treated with aloes, and if this comes in contact with wool containing iron, a stain is formed. This is not the stain generally complained of. A number of samples of discoloured naphthalene used contained traces of phenols. When wool was impregnated with these and then sweated in a steam oven, slight stains (as distinct from colourings) were developed, whereas stain did not develop when pure naphthalene melting at 79° C. was used. The stain is more marked with wools in the grease. Pure naphthalene, to which 0·05 per cent. phenol had been added, developed a marked stain. When the wool was first impregnated with a very weak iron solution, and the process with phenolic naphthalene repeated, a heavy stain which resisted the usual chemical bleaches resulted. These are the usual trade conditions in an exaggerated form. The results, although insufficient to form the basis of any definite conclusion, suggest that amino bodies in wool and grease are diazotised during fermentation, or by the oxidation of the ammonia set free—especially during the sweating process. These diazotised bodies couple with phenolic bodies to form dyes, which are fixed in the wool by the iron acting as a mordaunt. It seems that coloured naphthalene often contains phenols which are a source of stain in wool, so that only pure naphthalene should be used as a wool preservative.

Price Movements of Metals, 1922

The appended diagram, reproduced by permission from the *Bulletin of the Federation of British Industries*, shows the movements of the prices of iron, steel, tin, lead and coal during 1922.



Saltpetre in China

Not inconsiderable quantities of saltpetre-bearing earth are found in the Chinese provinces of Hunnan, Shantung, Chihli, and Chitiang as well as in Mongolia. The material does not occur in definite geological deposits, but the saltpetre is continually being formed by the action of organisms on ammonium salts in the presence of alkali carbonates derived from the weathering of the loess. The action is assisted by the favourable climate, as the temperature rarely falls below 5° C. (41° F.), and in summer rises to 37° C. (98° F.). Saltpetre is recovered from the loose earth by a crude method of leaching, which yields about 2 lb. of the crude salt per 100 lb. of earth. This product on purification yields a fine white crystalline product containing only potassium compounds, of which about 2000 tons is produced per annum. Both the Japanese and the Americans are beginning to turn their attention to these deposits which, with more scientific methods of working, should become very important.

Research on Fireproofing Wood

Recently Messrs. W. O. Banfield and W. S. Peck published in *Canadian Chemistry and Metallurgy* (6, 8, 172), the results of some experiments carried out under the direction of Prof. Archibald at the University of British Columbia to determine the effect of chemicals on the ignition temperature of wood. The furnace used was formed of two circuits of nichrome resistance ribbon mounted inside a suitable outer casing and was thoroughly heated and allowed to cool to 100° C. before insertion of the specimens. British Columbia Douglas Fir was cut into test pieces, 8″×2″×2″, which were dried at 90° C. to constant weight, and after impregnation with various chemicals, again dried to constant weight.

Four methods of impregnation were tried, namely (*a*) immersing the specimen in a cold solution, (*b*) immersing the specimen in a hot solution, (*c*) placing the specimen in a closed vessel and applying solution under pressure of 50 to 60 lb., (*d*) placing the specimen in a closed vessel, and after treatment under a vacuum for 5 minutes, again applying the solution under a pressure of 50 to 60 lb. Of these methods (*d*) gave the highest concentration of salt placed in the wood in one impregnation, the next best being method (*c*), whilst methods (*a*) and (*b*), although differing very little from one another, gave concentrations much below those obtained by the other methods. The results show that wood impregnated with cupric, bismuth, ferric, and stannic chlorides, alum and barium sulphates ignites below 290° C., and these chemicals can therefore be considered as fire promoters; ammonium and sodium chlorides, boric acid and aluminium sulphate have little effect, the burning temperature being 290 to 300° C.; whilst a fire-retarding effect, at a temperature above 300° C., is produced by zinc, magnesium, and calcium chlorides, ammonium sulphate and phosphate, borax, sodium silicate, zinc ammonium phosphate and a mixture of phosphate and borax. The best salt tested was ammonium phosphate, which evolves an incombustible gas and leaves a covering of orthophosphoric acid on the wood fibres. The authors conclude with a list of properties which an ideal fire-resisting medium should possess.

Chemical Industry in the Netherlands

There are more than a dozen large chemical factories in Holland. Two of these, situated in Amsterdam, work in connexion with the quinine factory at Bandoeng, Java, and produce all kinds of quinine salts. A cocaine factory, also in Amsterdam, manufactures, in addition to cocaine salts, homatropine, tropacocaine, and novocaine. Glycerin and organic chemicals such as vanillin, coumarin, pharmaceutical chemicals such as hexamine, silver salts, salol, various alkaloids and nitrogenous fertilisers are made in a factory at Naarden, which, prior to the war, supplied all the glycerin used in the dynamite factories for the South African mines. Flavouring extracts, soluble essences, floral attars, and therapeutic and pharmaceutical products are specialities of a factory in Amersfoort, and an Amsterdam firm makes, at Katwyk, theobromine, hexamethylene tetramine, caffeine, lecithin, quinine, and absolute alcohol. Caffeine is the chief product, the annual output being about 55,000 lb.; it also produces about 130,000 lb. of formaldehyde and quantities of urotropine and tannoform made from it. A firm in Amersfoort specialises in rennet extract, malt extract for the textile industry, butter colours, and a bleaching agent for treating oils and flour. Fertilisers, especially superphosphates, are made in increasing quantities in Zwyndrecht, milk sugar is produced in Uitgeest, and a company in Tilburg has a daily output of about 1 metric ton of coal-tar dyes and 200 kg. of intermediates. Apart from formaldehyde derivatives and superphosphate, Dutch chemicals are mostly exported. The exports during the first six months of 1921 and 1922 were as follows:—

	January—June 1921.	January—June 1922.
	Metric tons.	Metric tons.
Acetic acid	1,150	1,804
Essential oils and turpentine	45	82
Synthetic perfumery	48	102
Soda products	160	378
Potash, caustic, etc.	782	1,521
Magnesia	3,122	5,142
Sulphuric acid	3,150	4,521
Saccharin	7	16
Glue	615	947
Gelatin	314	582
Quinine sulphate	29	85
Flavouring extracts	72	97

Exports of chemicals in the first half of 1922 amounted to 42,198 t., valued at $6,958,722, compared with 25,054 t., worth $5,151,000, during the same period of 1921. Imports during the same period rose from 89,146 t. ($8,428,000) to 123,589 t. ($9,316,746), and included many raw materials as well as products not manufactured in the Netherlands.—(*U.S. Com. Rep., Oct.* 30, 1922.)

The Uses and Properties of Ethylene Glycol

An interesting article is published in the January 24 issue of *Chemical and Metallurgical Engineering*, describing the properties of ethylene glycol, a solvent, reagent, and preservative of unusual properties, which has become available through recent commercial developments. The pure liquid has the formula $C_2H_4(OH)_2$, and is water-white (sp. gr. 1·116), odourless, sweet tasting, and non-volatile. On exposure to air it attracts moisture, thus giving it valuable moistening properties. It has a low freezing point, and serves well to lower the freezing point of water solutions. It has many of the characteristics of ethyl alcohol, being miscible with water, and an efficient solvent for esters, medicaments, resins, flavours, and dyes, but has none of the intoxicating properties of ethyl alcohol, and is quite harmless when taken internally, even in large amounts. Ethylene glycol also possesses marked preservative properties against bacteria. It, however, is so new to industry that all its uses have not been ascertained, but it will probably eventually take rank with ethyl alcohol and glycerin as an industrial material. Already it has found application in the preparation of explosives and of glycol dinitrate as a solvent for cellulose esters, and it apparently may find uses similar to those of the glyceryl acetates used in the printing and dyeing of cotton.

Agricultural Industries in Jamaica

The report of the Jamaican Department of Agriculture for 1921 states that, although the year was favourable for agriculture, it marked a period of severe commercial depression. The sugar industry was saved from ruin only by prompt legislation, but now, in comparison with the neighbouring colonies, Jamaica is not unfavourably placed for further development. In consequence of the drought in 1920, exports of sugar in 1921 fell by 8000 t. to 26,000 t., the value declining enormously. Of the export of sugar, 55 per cent. was directed to Canada and 41 per cent. to England. The banana industry is rapidly regaining its pre-war position, but the export of coconuts declined from 28 to 24 millions, copra showing an increase in quantity but a reduction in value. A slight recovery was made by the logwood industry, exports of wood being valued at £28,000 and of extract at £109,000, compared with £269,000 and £431,000, respectively, in the previous year. Sales of orange oil were valued at £40,000 and the export of citrus fruit continued at the same level as in 1920. There was an increased export of both cacao and coffee, but values were much lower.

Exports of pimento rose from 3000 t. to 4000 t., valued at £11 per ton. The pimento-oil industry has been further investigated by the Industrial Chemist and it is stated that where pimento leaves and wood fuel are available, the manufacture of the oil would be profitable with pimento oil worth 8s. to 10s. per lb. in the world's markets. A local capitalist intends to establish a factory capable of producing 10,000 lb. of pimento oil per annum. The sisal industry is now beginning the manufacturing stage and three factories at Clarendon and the Government factory at Lititz will be in operation during the present year. Experiments at Lititz gave encouraging results, the fibre extracted rising to 5·7 per cent., and the yield per acre being 1433 lb. A crop of 200 t. of fibre is anticipated at Lititz in 1922–23 and in 1924–25 it should be 500 t., equal to the capacity of the factory. There was a poor demand for hides, but goat-skins valued at £21,000 were exported.

The Chemical Market in France

Since the beginning of January, quotations for oil of turpentine have risen from 635 francs per 100 kg. on rail at Bordeaux to 670 fr. (January 13). Consequently there is little demand, and purchasers are holding back. Quotations for industrial fats rose to 242·50 fr. per 100 kg. on the Paris market on January 12; there was a lively demand, but supplies were scarce.

REVIEWS

KOLLOIDCHEMIE, 1914—1922. *By* Dr. R. ED. LIESEGANG. *Pp. viii*+100. *Dresden and Leipzig: Theodor Steinkopff*, 1922. *Price* 3*s*. 4*d*. *net.*

This volume forms one of a series of "Wissenschaftliche Forschungsberichte," the object of which is to give a summary of the work accomplished in various fields of research during the period when the interchange of scientific publications was interrupted by the war and by economic conditions. Such a survey is particularly desirable in the case of colloid chemistry, important contributions to which are to be found in journals of the most varied kind. Dr. Liesegang has for many years edited the abstract section of the "Kolloid-Zeitschrift," and is thus well qualified for a task which he has discharged with skill and discretion. As the small volume gives well over 600 references these are necessarily brief, but they are sufficiently explicit and judicious to tell the reader what publications he ought to study in detail. The book will be found a most useful guide by all interested in colloid chemistry and its numerous applications.

Printing and paper are quite good, and the text is almost free from misprints.

EMIL HATSCHEK

THE THEORY OF EMULSIONS AND EMULSIFICATION. *By* W. CLAYTON, *with a Foreword* by Prof. F. G. DONNAN. *Pp. viii*+160. *London: J. and A. Churchill*, 1923. *Price* 9*s*. 6*d*. *net.*

Dr. Clayton's book is the first one to give a comprehensive account of a class of disperse systems, the importance of which, emphasised in Prof. Donnan's foreword, has been generally realised by authors of works on colloid chemistry. In most of these works some space is devoted to emulsions, although those emulsions which claim the chief interest are all much coarser than typical collodial systems.

After giving a description of the principal properties of emulsions and of the agents used to produce them, the author discusses in great detail the various theories which have been put forward to explain emulsification. Incidentally a clear account of adsorption and of the attempts to verify the Thomson-Gibbs formula quantitatively is given. The author—in common probably with most recent workers—seems to favour the adsorption film theory. Its bearing on the interesting, and still by no means completely explained, phenomenon of the reversal of phases also receives adequate treatment. These chapters furnish the reader with a lucid and impartial statement of the present state of our knowledge.

The title of the book does less than justice to its contents, inasmuch as the two concluding chapters on "Emulsification" and "De-emulsification" contain a great deal of technical information on large scale apparatus and procedure which has not been readily accessible so far. The large number of industrial processes in which the separation of emulsions forms an important and difficult problem may come as a surprise to many readers.

A very complete bibliography, going back to 1865, in which the reviewer has not been able to detect any omissions, completes the book and adds to its value.

Printing and binding conform to the high standard of the series, which includes this book, but it is not very obvious why the size of the page should have been altered from that of the other volumes.

EMIL HATSCHEK

CEMENTS AND ARTIFICIAL STONES. *By the late* JOHN WATSON. *Pp. xii*+131. *Cambridge: W. Heffer and Sons, Ltd.*, 1922. *Price* 6*s*. *net.*

The literature of cement and artificial stones is sufficiently plentiful, and it is a relief to find that this little book is neither a text-book nor a monograph, being indeed a museum catalogue.

To many the museum of the past must have resembled the valley of the prophet, which was full of bones—"and, lo! they were very dry." The question, "Can these bones live?" has been answered admirably by the late Mr. John Watson for the specimens in the Sedgwick Museum, Cambridge. No doubt there are now many similar catalogues, and the modern student is to be congratulated in that his path among the exhibits is not the arid track that his predecessors found it.

In the work before us 136 specimens arranged to illustrate the raw materials, intermediate products and finished manufactures of the industries in question are described for the student of economic geology. The point of view does not admit of discussion of chemical changes and constitution, which is a little refreshing to the chemist, to whom a couple of hours' reading without reference to colloidal chemistry is sometimes restful. The reasons for the selection of material, the processes of manufacture and the properties demanded of the products are, however, lucidly and interestingly expounded.

In the short historical introduction we are reminded that the great Portland cement industry will celebrate its centenary next year; the patent of Joseph Aspdin for the manufacture of a cement which, when moulded, closely resembles Portland stone, being dated 1824. The specification, we may hope, would not have passed the examiner of the present day, for when Messrs. White, of Thames and Medway fame, instructed their manager, Mr. I. C. Johnson, to imitate the Aspidin cement, he failed; this may have been partly due to the analyst to whom Johnson submitted the cement, for that worthy's report, which is set out in full in this book, contains no reference to silica, the main constituent being $Ca_3(PO_4)_2$! It is good to note that "subsequently the London chemist admitted that the analysis was incorrect." Johnson was equal to the task, however, as most will recollect, and lived to see the industry develop in a manner which has been equalled by few; he died in 1911, aged 100.

Commenting on the specimens of chalk marl, the author alludes to the possible extensive production of Portland cement near Larne, where the Antrim deposits of Senonian chalk lie close to marine clays well suited for the purpose; it may be hoped that specimens of Irish Portland cement will soon be added to the museum.

More than once occasion is found to criticise the constructional trades in respect of the lack of interest they show in the training of those whose business it is to apply cement, such as the man who is commonly called the concreter. The architect and engineer are exhorted to look to this, but it may well be submitted that the chemist is here at fault; the Chemical Engineering Group, please note.

The museum contains several specimens of proprietary articles; the descriptions of these smack somewhat too much of the trade circular, but since in most cases instances are given of buildings in the construction of which the materials have been used, the proportion of fact to fancy in the account given is probably greater than is common in the vendor's announcements.

The reviewer is left with the impression that he will live to reside in a house comprising little else than cement and its products; in the meantime he has to thank the author for a pleasant companion to an evening pipe.

A. G. Bloxam

REPORTS

Reports on the Economic and Financial Situation in the Republics of Panama and Costa Rica to September, 1922. *By* W. Ewing, *Acting H.M. Consul, Colon, and* A. Murray, *Acting H.M. Consul, San Jose. Pp.* 32. *Department of Overseas Trade. London: H.M. Stationery Office,* 1922. *Price* 1*s*.

Panama.—One result of the persistent stagnation of trade (*cf.* J., 1922, 136 R) has been the focussing of attention on the commercial welfare of Panama and on the development of local production and industry. Banana exports overshadow all others in importance. Sugar production is increasing and, it is anticipated, will soon be sufficient to supply the home demand. The American firm working the manganese deposits expects shortly to resume shipments from Nombre de Dios.

The total exports from Panama in 1920 were valued at 3,551,895 balboas (balboa=U.S. gold dollar). Full details are not given, but coconuts were exported to the United States to the value of \$364,531, and to the United Kingdom to the value of \$13,750; balata, U.S.A. \$26,722, U.K. \$65,952; medlar gum, U.S.A. \$12,318, U.K. \$39,129; sarsaparilla, U.S.A. \$2728, U.K. \$39,698. Imports, very varied in nature, were valued at \$17,326,430, of which the United States supplied 75·1 and the United Kingdom 9·1 per cent. In 1921 exports fell to \$2,495,407, of which the United States took 97 per cent. and the United Kingdom less than 0·5 per cent. Imports amounted in the same period to \$11,372,370, of which the United States supplied 75·2 and the United Kingdom 7·9 per cent. The volume of the trade of Panama with the United Kingdom was decreased largely in the past few years owing to the headway made by the United States during the war period. It is considered, however, that there is still hope of extending British trade, though at present the outlook is not encouraging. The British goods which have hitherto found the best market have been various textiles, alcoholic liquors, chemical products, castor oil, and soap.

Costa Rica.—The principal products of this country are bananas, coffee, sugar and cacao. Exports in 1921 were valued at £3,095,548 (£2,563,929 in 1920), the United States taking 68·1 and the United Kingdom 25·1 per cent. Among the items were:—Bananas, £1,511,369; gold and silver bullion, £161,660; manganese ore, £4598; sugar and panela, £125,293; coffee, £998,733. Imports decreased from £3,654,873 in 1920 to £2,390,600 in 1921, when the United States supplied 55·9 and the United Kingdom 16·9 per cent. Among the products supplied by the United Kingdom and Colonies were drugs and chemicals, £12,954; soap, £5024; paint, £4041; perfumes, £2817; china and glass, £7956; leather goods, £2966.

Report on the Economic and Financial Conditions in Paraguay, Dated September, 1922. *By* F. W. Paris, *H.M. Consul, Asuncion. Pp.* 19. *Department of Overseas Trade. London: H.M. Stationery Office,* 1922. *Price* 6*d*.

The recovery of Paraguay from post-war conditions (*cf.* J., 1922, 136 R) has been retarded by political unrest, and although industry has received a fresh shock at a most inopportune moment, optimism prevails as to future progress. In 1921 the "Scientific Society of Paraguay" was constituted at Asuncion and proposes to issue a review containing articles by experts. In April, 1922, a small firm, reputed to be supported by powerful British oil interests, applied for a concession granting the exclusive right to prospect for and exploit petroleum within 30 miles of Asuncion. Such concerns as breweries, flour mills, and soap and biscuit factories appear to be holding their own, but owing to slackness in the building trade, lime and brick factories, and allied industries, are passing through a critical period.

Quebracho extract (tannin) was exported in 1921 to the extent of 29,356 tons, or 5295 tons more than in 1920; the price at the beginning of 1922 tended to improve, but constant floods in the Chaco district, where the quebracho tree grows, made transport of the logs difficult during most of the year (see *Chem. & Ind.*, 1923, p. 19). The number of hides exported in 1921 was 190,813, against 198,965 in 1920, and 312,532 in 1913; this apparent fall is probably due in part to the clandestine export which has occurred since the imposition of an export tax in 1916. The output of sugar in 1921 is given as 2579 tons, 1200 tons less than in 1920 and insufficient for local needs. The 1921 output of rectified spirit, 366,409 litres, and of rum, 424,312 litres, is much below that of 1920. Cotton growing is still being extended, and the 1922 crop is estimated at 1000 tons. Exports from Paraguay amounted in 1921 to £1,863,344 (£1=5 gold pesos) against £3,037,116 in 1920. In 1921 the Argentine took 70·2 per cent., the United States 11·8 per cent. and Uruguay 8 per cent. of the total. Imports decreased from £2,623,701 in 1920 to £1,671,784 in 1921, when they included iron and steel valued at £359,074; chemicals, etc., £129,091; leather manufactures, £18,244; glass and chinaware, £17,099. Of the total the United Kingdom supplied 21, the United States 17, Argentina 39 and Germany 7 per cent. Probably a large proportion of the merchandise imported from Argentina is of British origin.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for February* 8)

TARIFF CUSTOMS EXCISE

Argentina.—It is proposed to introduce a new Customs tariff, under which the valuation tariff may possibly be increased.

Australia.—The "dumping exchange" duty has been applied to aspirin of German origin and the "dumping preference" duty to scientific glassware and apparatus of German origin.

Belgium.—The export is prohibited of bricks, tiles, scrap-metals, coal-tar, pitch and bones. A licence is required for the export of sugar.

Canada.—Under the British preferential tariff pulp board is admitted duty free, and under the other tariffs at the rate of 5 per cent. *ad valorem.*

French West Africa.—The "coefficient of increase" applied to the export duty on hides and skins has been raised from 1 to 5.

Morocco (French).—Increased consumption duties have been applied to sugar.

New Zealand.—Regulations have been issued controlling the application of the special duty on goods from countries with depreciated currencies.

Poland.—The consumption taxes on lubricating oils, paraffin wax, candles, asphalt, coke and tar have been increased, as have the excise duties on alcohol, coal, pressed yeast, matches and sugar.

United States.—Goods affected by the "countervailing" (retaliatory) duties include bricks, calcium acetate, chloride, nitrate and cyanamide, coal, etc., certain explosives, paper board and pulp board.

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Argentina	Galvanised sheets, tinplate, paper, chemicals, sodium silicate, soda crystals	189
Australia ..	Hardware, enamelware	155
,, ..	Iron and steel	156
,, ..	Copper sulphate (tender for)	10544/E.D./C.C./2
,, ..	Copper wire	10539/E.D./E.P.
,, ..	Ammonium chloride ..	10542/E.D./1/C.C./2
,, ..	Leclanché porous cells and earthenware outer jars	10542/E.D./2/M.C./2
Belgium ..	Copper bars, sheets, tubes	18519/F.W./E.P.
Brazil ..	Galvanised and black sheets, copper and brass bars, etc. ..	192
British India	Cement, soap, perfumery, paper, glassware ..	158
Canada ..	Tinplate, brass	159
France ..	Pharmaceutical products	171
Italy ..	Chile nitrate	174
Netherlands	Cottonseed oil	177
Norway ..	High-speed steel ..	178
,, ..	Copra	179
South Africa	Industrial raw materials	164
,, ,,	Oxygen gas	10549/E.D./C.C./2
Sweden ..	Cut glass	184
,, ..	Varnish, dyes	185
Syria ..	Potash alum	187
United States	Shellac	18088/F.W./C.C./2

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

There is little or no change to record in the chemical market. The demand for "heavies" continues well maintained in most directions, but any development of better trade is still hampered by uncertainties in the direction of foreign politics.

Acid Acetic, 40% tech.	£22 per ton. Firmness of position continues with tendency for price to rise.
Acid Hydrochloric	4s. to 5s. carboy d.d.
Acid Nitric, 80° Tw.	£25 10s. per ton. Still in very poor demand.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw., is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d. to £8 per ton. Rather quieter tone.
Arsenic (White)	£75 per ton. Shortage continues, but inquiry not quite so brisk.
Bisulphite of Lime	£7 per ton, packages extra and returnable.
Bleaching Powder	£10 10s. per ton. Not much change.
Calcium Chloride	£6 per ton d.d. Considerable quantities reported imported from Continent.
Copper Sulphate	£26 10s. per ton f.o.b.
Potash Caustic, 88/90%	£29-£30 per ton. No change.
Potass. Bichromate	6¼d. per lb. d.d.
Salammoniac	£32 per ton d.d.
Salt Cake	£4 10s. to £5 10s. per ton. Considerable American inquiry, but not much business passing up to the present.
Soda, Caustic, 76%	£20-£21 per ton. In slightly better request.
Soda Crystals	£5 10s. per ton carr. paid. No change.
Sod. Acetate, 97/98%	£23 10s. per ton. In fair demand. Price firm.
Sod. Bicarbonate	£10 10s. per ton. Still in fair demand.
Sod. Bisulphite Powder, 60/62%	£19-£20 10s. per ton f.o.b. or f.o.r. London.
Sod. Chlorate	Market very dull and prices not at all firm.
Sod. Nitrite	£30 per ton 100% basis d.d.
Sod. Sulphide, solid	£16 per ton carr. paid. Price unsteady and demand still very poor.
Sod. Sulphite, Pea Crystals	£17-£17 10s., 1-cwt. wooden kegs included.

WOOD DISTILLATION PRODUCTS

There is a brisk inquiry for products generally and prices remain firm or show a slight upward tendency. Charcoal is in good demand, particularly the higher grade home-produced retort variety. Naphtha prices remain steady and unchanged, but American quotations are falling, a factor that will speedily influence the home market.

Acetate of Lime—	
Brown	£9 per ton d.d.
Grey	£15 10s. per ton d.d., but prices as high as £19 per ton are reported for imported parcels.
Liquor	9d. per gall. 32° Tw. d.d.
Charcoal	£9 10s.-£10 per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 6d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	7s. ,, ,, 80% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£5 per ton d.d.
Brown Sugar of Lead	£38 per ton d.d.

TAR PRODUCTS

Acid Carbolic, Crude, 60's	2s. 6d. to 2s. 10d. per gall. Fair inquiry for spot and forward.
Acid Cresylic—	
97/99	2s. 3d. per gall. Good business being done.
Pale 95%	2s. 1d. to 2s. 2d. per gall.
Dark	1s. 10d. to 2s.
Anthracene Paste, 40%	7d. per unit per cwt. Price still nominal.
Anthracene Oil—	
Strained	9d. to 11d. per gall. Fair enquiry.
Unstrained	8¼d. per gall.
Benzole—	
Crude, 65's	1s. 1½d. to 1s. 2d. per gall. f.o.r. makers' works.
Standard Motor	1s. 8d. to 2s. per gall.
Pure	2s. to 2s. 2d. per gall.
Toluole—90%	1s. 9d. to 2s. per gall.
Pure	2s. to 2s. 2d. per gall.
Xylol	3s. 3d. per gall.
Creosote—	
Cresylic, 20/24%	10½d. to 1s. per gall.
Middle Oil	7¾d. to 9¼d. per gall. Good demand.
Heavy	
Standard Specification	
Naphtha—	
Crude	9d. to 10d. per gall.
Solvent, 90/160%	1s. 7d. to 1s. 10d. per gall. Not much enquiry.
Solvent, 90/190	1s. 7d. per gall.
Naphthalene, Crude—	
Drained Creosote Salts	£6 to £7 10s. per ton. Market short.
Whizzed or Hot Pressed	£9 10s. to £12 per ton.
Pitch, Medium Soft	140s. to 150s. per ton f.a.s. Numerous inquiries, market strong.
Pyridine—90/140	10s. 6d. to 12s. 6d. per gall.
Heavy	8s. 6d. to 9s. per gall. Not much inquiry.

INTERMEDIATES AND DYES

Business in Aniline Dyestuffs has been good during the week. Orders have increased both in quantity and weight. Customers have got more confidence and are certainly buying freer with more tendency to look forward than in the past. Prices remain the same but firm.

Acetic Anhydride ..	1s. 5d. lb. 100% basis.
Acid H.	5s. 1d. lb. 100% basis.
Acid Naphthionic ..	2s. 7½d. lb., 100% basis.
Acid Neville and Winther	6s. lb. 100% basis.
Acid Sulphanilic ..	1s. 6d. lb. 100% basis.
Aluminium Chloride, anhyd...	1s.
Aniline Oil and Salts ..	10d. lb. naked at works.
Antimony Pentachloride	1s. 1d. lb.
Benzidine Base	6s. 6d. lb. 100% basis.
Benzyl Chloride ..	1s. 4½d. lb. 100% basis.
Dinitrobenzene	11d.-1s. lb. naked at works.
Dinitrochlorbenzol ..	£95 per ton.
Dinitrophenol	£140 per ton.
Dinitrotoluene—48/50 ..	8d.-9d. naked at works.
66/68 ..	1s. 2d.-1s. 3d. naked at works.
Diphenylamine	4s. 1d. lb.
Dichloraniline	2s. 2d. 100% basis.
Dichloraniline S. Acid ..	2s. 4d. 100% basis.
Diethylaniline	4s. 6d. lb., packages extra.
Metanitraniline	5s. 6d. lb.
Meta Phenylene Diamine	5s. 6d. lb.
Meta Toluylene Diamine	5s. lb.
Monochlorbenzol ..	£70 per ton.
α-Naphthol	2s. 9d. per lb.
β-Naphthol	1s. 1d. lb.
α-Naphthylamine ..	1s. 6½d. lb.
β-Naphthylamine ..	4s. 6d. lb.
p-Nitraniline	2s. 8d. lb.
Nitrobenzene	7½d. lb., drums extra.
Nitronaphthalene ..	1s. lb.
Naphthionate Soda ..	2s. 8½d. lb. 100% basis.
Orthonitrochlorbenzol ..	2s. lb.
Paradichlorbenzol ..	£55 ton.
Paranitrochlorbenzol ..	1s. 4d. lb.
Paranitrophenol ..	1s. 9d. lb. 100% basis.
Parachloraniline ..	3s. lb. 100% basis.
p-Nitro-o-amido phenol	4s. 6d. lb. 100% basis.
Para Phenylene Diamine	12s. lb. 100% basis.
Para Toluidine	5s. lb.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

The general demand for pharmaceutical chemicals is still poor and most prices are unchanged in consequence. Stocks of some items are none too plentiful, and in the event of any material demand higher prices will be asked.

Acid Acetic, 80% B.P...	£45-£47 ton. Good inquiry. Prices have upward tendency.
Acid Acetyl Salicylic ..	3s. lb. Market exceedingly firm owing to continued increase in cost of raw materials.
Acid Benzoic	2s. to 2s. 2d. lb. Not much on offer for spot delivery.
Acid Boric, B.P. ..	£61 ton Crystals, £65 ton Powder. Packages in 2-cwt. bags. Carr. paid U.K. Market very steady.
Acid Citric	1s. 7d. to 1s. 9d. lb. A little more inquiry.
Acid Gallic	3s. lb.
Acid Pyrogallic, cryst. ..	5s. 6d. lb.
Acid Salicylic	1s. 6d. lb. Without much demand at this higher price.
Acid Tannic	3s. 3d. lb. Unchanged.
Acid Tartaric	1s. 2½d., less 5%, with foreign make in fair supply at 1s. 2d. lb.
Acetanilide	1s. 6d. lb. neglected.
Amidopyrin	14s. lb.
Ammon. Benzoate ..	Still 3s. lb. for good makes.
Ammon. Sulphocyanide	2s. 6d. lb. for recrystallised.
Barbitone	12s. 6d. lb.
Benzonaphthol	5s. lb.
Bismuth Salts	Prices per lb. for cwt. lots are as follows :—Carbonate 13s., Citrate 11s. 7d., Nitrate cryst. 6s. 11d., Oxide 14s. 5d., Salicylic 10s. 5d., Subchlor 12s. 8d., Subgallate 9s. 6d., Subnitrate 11s. Fairly good market.
Bromides	Still in plentiful supply. Market unsettled.
Chloral Hydrate ..	4s. 3d. lb. A firm market.
Formaldehyde, 40% ..	£90-£98 ton.
Guaiacol Carbonate ..	8s. 6d. lb. for small quantities. 8s. lb. would be accepted for 1-cwt. lots.
Hexamine	4s. lb. now asked for spot parcels.
Homatropine Hydrobromide	30s. oz.
Iron Ammon. Citrate— B.P.	2s. 5d. lb. Market steady but not much doing.
Green	3s. 1d. lb.
Magnesium Carbonate— Light Commercial ..	£40 ton.
Magnesium Oxide— Light Commercial ..	£85 ton.
Heavy Commercial ..	£29 ton.
Menthol	37s. 6d. lb., less 2½% for original cases. Small quantities 38s. nett.
Methyl Salicylate ..	2s. 3d. lb. Slightly higher.
Methyl Sulphonate ..	13s. lb.
Mercurials	Much weaker in view of the lower cost of quicksilver.
Paraldehyde	1s. 6d. lb.
Phenacetin	5s. lb. Unchanged owing to lack of demand.
Phenazone	7s. lb.
Phenolphthalein ..	5s. 3d. lb. Still asked but lower prices would be acceptable for definite orders.
Potass. Bitartrate 99/100% (Cream of Tartar)	97s. 6d.-100s. cwt. for ton lots, less 2½%. Market firm.
Potass. Iodide	15s. 8d. lb. for cwt. lots. Cases free. Demand still good.
Potass. Metabisulphite..	8d. lb.
Potass. Permanganate ..	8½d. lb.
Quinine Sulphate ..	2s. 3d.-2s. 4d. oz. Bulk packages. Fairly steady market.
Resorcin	5s. lb. now quoted for good "white."
Salol.	2s. lb. Unchanged.
Sod. Benzoate	2s. 2d. lb. Still in short supply.

Sod. Citrate	U.S.P. quality, 2 mols, water, quoted at 2s. 2d. lb. for cwt. lots. B.P.C. quality, 5½ mols. water, 2s. lb.
Sod. Salicylate	2s. for powder, 2s. 1d. for crystal. These prices show little profit to the manufacturers and higher rates are expected in the near future.
Sod. Sulphite, anhydrous	£27 10s.-£28 10s., according to quantity, f.o.r. London, drums included.
Sod. Sulphite Pea Crystals	£17-£17 10s. ton, according to quantity.
Thymol	17s. to 19s. lb., according to quantity. Much firmer.

PERFUMERY CHEMICALS

Amyl Acetate	2s. 3d. lb.

TRADE NOTES

Pasteur Centenary Exhibition

At the Pasteur Celebrations which will be held in Strasbourg in May, an exhibition will be opened, designed to show the advances made in the domains of medicine, hygiene, industry and agriculture as the result of the labours of Pasteur. All British manufacturers who are interested in the exhibition and are willing to assist, are asked to communicate with Professor Borrel, 3, rue Koeberle, Strasbourg.

Rubber Exports from British Malaya in 1922

An official cablegram from Singapore states that the exports of rubber from British Malaya in December amounted to 18,427 tons (41,276,500 lb.), as against 21,642 t. in November and 18,354 t. in the corresponding month of 1921. Transhipments amounted to 798 t. (1,787,200 lb.) and foreign imports to 4569 tons (10,235,000 lb.). The total export of plantation rubber from British Malayan ports in 1922 was, approximately, 248,157 t. Transhipments during the year amounted to about 21,838 tons.—(*Bd. of Trade J., Jan.* 11, 1923.)

Output of Coal, July—Sept., 1922

Statistical summary of output of the coal mining industry for Great Britain for the quarter ended September 30, 1922:—

	Output of saleable coal, less mine consumption and miners' coal.	Output of saleable coal per man-shift. cwts.	Earnings per man-shift. s. d.
Scotland	7,310,000	19·52	9 3
Northumberland	2,958,000	17·13	8 4
Durham	8,239,000	17·74	8 11
South Wales and Monmouth	10,737,000	16·74	9 7
Yorks, Notts, Derby, Leicester, Cannock Chase, etc.	17,577,000	20·50	9 11
Lancs, North Staffs and Cheshire	4,991,000	14·43	8 8
North Wales	620,000	12·91	7 11
South Staffs and Salop	364,000	17·43	8 0
Cumberland	413,000	13·64	9 7
Bristol	76,400	11·08	7 10
Forest of Dean	154,000	13·65	7 9
Somerset	170,000	13·45	7 2
Kent	84,000	19·82	12 10
Summary	53,694,000	17·94	9 4

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, FEBRUARY 23, 1923 No. 8

EDITORIAL

THE opening of the new Botanical Laboratory of the Imperial College of Science and Technology by the Duke of Devonshire, recorded elsewhere in this issue, marked further and most gratifying progress in the provision of facilities for training men capable of applying science to industry. Ever since its inception, the Imperial College has steadfastly kept this aim in view and due recognition of the importance and success of its work has been provided by the generous contribution by the Rubber Growers' Association of London of £30,000 towards the cost of the new building. That such a large sum should be contributed by representatives of an industry that has only just passed through the most difficult period in its history affords striking proof of the growing appreciation of the vast benefits that can be obtained by the judicious application of science to technological ends. No small credit is due to Professor J. B. Farmer, professor of botany in the Imperial College, for his foresight, over a quarter of a century ago, in anticipating the inevitable and growing demand for men with a training fitting them to investigate industrial problems. Plant technology is comparatively a new science, but its importance cannot be over-estimated, as it insures the supplies of raw materials that are essential to the industrial existence of this country. Calling, as plant technology does, for the collaboration of the botanist, zoologist, physicist and chemist, the words of an experienced rubber-grower, quoted by Sir A. Dyke-Acland, are of especial interest, as he asked not for rubber technologists but for men with a sound scientific training, because such men would learn more about rubber in a month on the plantation than in years spent in the laboratory. This advice, it would appear, has been acted on by the Imperial College, and its wisdom in so doing is exemplified by the erection of the new laboratory. Facilities are provided in the building for work in bacteriology, or what is now called microbiology, and in biochemistry as well as in pure botany, and it is to be hoped that, as in the past, the training will continue to produce whole chemists and whole botanists and not sterile hybrids.

The scientific journals and the daily newspapers have, during the last few days, contained quite a number of references to Hafnium and this element seems likely to produce an extremely interesting discussion. Professors Urbain and Dauvillier, in a letter published in *Nature* on the 17th instant, recall that two lines of the element whose atomic number is 72 were observed in the X-ray spectrum in the last fractions remaining after fractionating some nitrates of the ytterbium group. As these could not be attributed to any known element they were ascribed to a new element, celtium. (G. Urbain, *Comptes rendus*, t. 152, p. 141, 1911.) The other rays of this element seemed to coincide with rays of lutecium and neo-ytterbium. One of these French professors has recently investigated a sample of zirconium and finds that it produces rays which exactly coincide with the rays of the ytterbium fraction already mentioned; the wave-lengths of two of these lines have been found to be β_2-1322 and α_1-1564 U.X. According to Professors Coster and Hevesy, the wave-lengths of hafnium are α_1-1565, β_2-1323, so that the agreement seems to be good. Urbain and Dauvillier point out that the tetravalency of element 72 is not an objection to an element associated with the rare earths. Cerium is both tervalent and tetravalent and a constant equilibrium is maintained between the two varieties. Thorium also is always found in the ores of the rare earths, germanium is found with arsenic and molybdenum, and indium with zinc.

To add to the confusion it is now announced that the sample of "oceanium" which Dr. Scott sent to Coster and Hevesy does not show the X-ray spectrum of "hafnium." It is not yet perfectly clear whether the discussion and the experiments concern one element or two, or three, but in a few weeks this point should be cleared up, and we have good reason to hope that very shortly we shall receive communications from the five distinguished investigators who are working at this most fascinating problem. So soon as further information is available we will deal with the X-ray analysis of the rare earths and the elements which immediately follow them in greater detail than was possible in our previous notes on this subject.

The problem of the composition of coal is one which has, for a number of years, attracted many workers, and although progress has been made, and a vast mass of data accumulated, it cannot be claimed that we are, as yet, near the desired goal. This is hardly surprising, in view of the complexity on the material, and the ease with which it is decomposed. A large part of our knowledge of the nature of coal is based upon observations of the selective action of solvents on its constituents. De Marsilly in 1862 appears to have been the first to make a systematic study on these lines. Since that time much work has been done with benzene, chloroform, ether, phenol, pyridine, and other solvents, which has resulted in the separation of three fairly well-defined types of substances, namely, those insoluble in pyridine (the so-called α-compounds), those soluble in pyridine but insoluble in chloroform (β-compounds), and those soluble in pyridine and in chloroform (γ-compounds). As a natural consequence, perhaps, of our lack of definite knowledge of the subject, the nomenclature of coal is in an unsatisfactory state. The α- and β-compounds, which are derived from the vegetable celluloses and proteins, were formerly termed "cellulosic" compounds and the γ-compounds (resins, hydrocarbons, etc.), "resinic" compounds; whilst various other names, including humins, ulmins, etc., have been, from time to time, applied to the various components. It will also be recalled that coal can be separated, by hand, into four portions, "durain," "fusain," "clarain," and "vitrain," differing in appearance, but similar in composition and in the products they yield on heating. In a paper in the current "Transactions," Mr. A. R. Pearson puts forward a new terminology, in that he uses the names α- and β-ultrahumins in place of the above-mentioned α- and β-compounds, whilst he gives the name γ-ultrahumins to that portion of the coal substances which is soluble in pyridine and in chloroform, but is precipitated by ether. Mr. Pearson has studied the action of sulphuric acid on the separate ultrahumins, and has obtained a series of substances containing more oxygen than those from which they are derived; these he terms oxahumins, and he has further subjected them to the action of bromine. In both the oxahumins and their bromine derivatives the greater part of the nitrogen of the original compounds was retained, indicating the presence in the ultrahumins of a nitrogenous complex of considerable stability. The account of this work will be appreciated by those who are interested in this fascinating subject, but we may be permitted to question the desirability of adding a new phraseology to a subject regarding which so little definite is known.

THE BASIC STRENGTH OF AMMONIA AND ALLIED BASES

By PROFESSOR R. M. CAVEN, D.Sc.

In a recent number of "Chemistry and Industry" Professor T. M. Lowry has defined a base as "an acceptor of hydrogen nuclei," and has illustrated the acceptance of such nuclei or ions in the case of ammonia by the equations :—

$$NH_3+\overset{+}{H}\rightleftarrows\overset{+}{N}H_4 \text{ and } NH_3+HOH\rightleftarrows\overset{+}{N}H_4+\overset{-}{O}H$$

The purpose of the present communication is to develop this valuable idea, and to show how it elucidates the relations between ammonia and the ammonium salts, between ammonia and its alkyl derivatives, and between other non-metallic hydrides and their derivatives and salts. Since an aqueous solution of ammonia resembles one of sodium hydroxide in being alkaline it has long been supposed to contain ammonium hydroxide, NH_4OH. It has been assumed that when ammonia dissolves in water it combines more or less with the water to form ammonium hydroxide, which is then ionised to some extent thus :—

$$NH_3+H_2O\rightleftarrows NH_4OH$$

$$NH_4OH\rightleftarrows\overset{+}{N}H_4+\overset{-}{O}H$$

Whilst the hydroxidion concentrations of ammonia solutions of different strengths are known, no information has been furnished as to the proportion of non-ionised ammonium hydroxide present in these solutions.

That ammonia ordinarily behaves as a weak base cannot be disputed. The relative strengths of a number of bases in fortieth-normal solution are given by the following figures derived from the rate of saponification of methyl acetate which they cause (Walker: Introduction to Physical Chemistry, 8th ed., p. 311). Side by side with these are shown the hydroxidion concentrations of different ammonia solutions indicated by their electric conductivities (Bredig: Zeit. Physik. Chem., 1894, **13**, 269).

Base.	Relative strength.	Hydroxidion concentration of NH_3 aq.	
LiOH	100		
NaOH	98		
KOH	98		
$N(C_2H_5)_4OH$	75		
$N(C_2H_5)_3HOH$	14	N/100	4%
$N(C_2H_5)_2H_2OH$	16	N/10	1%
$N(C_2H_5)H_3OH$	12	N/1	0·3 to 0·4%
NH_4OH	2		

It may be noted that if lithium hydroxide in N/40 solution is assumed to be completely ionised, 2 per cent. of the ammonia in an equivalent solution is shown to have given rise to hydroxidions, and it appears that this degree of ionisation is roughly in agreement with that indicated by conductivity measurements.

The fact should be emphasised that the ammonia solution used as an analytical reagent contains upwards of 96 per cent., probably upwards of 99 per cent. of its ammonia as NH_3, apart from the assumption that any considerable proportion of non-ionised NH_4OH molecules are present.

Professor Lowry's view makes this assumption unnecessary and leads at once to the question whether ammonium hydroxide has any existence at all. Sodium hydroxide has been formed as an individual substance because sodions and hydroxidions have been produced in solution in sufficient concentration to be held together by electrostatic attraction. An alkaline solution of sodium hydroxide results from the dissolution of the union thus produced—union by electrovalency—through the action of the solvent. If ammonium hydroxide exists it must be formed similarly, by the mutual approach of its constituent ions. Ammonium- and hydroxide-ions are formed in aqueous solution of ammonia in low concentration. Is this concentration sufficient to cause electrostatic union so that individual molecules—if the term is now allowable—of NH_4OH are formed in solution ? The evidence for the existence of an electrolytic compound must be either that the compound has been isolated, or that it confers upon the solution in which it is said to exist distinctive and recognisable properties.

A hydrate of ammonia, $NH_3.H_2O$, exists at low temperature (Rupert, J. Amer. Chem. Soc., 1909, **31**, 866 ; Smits and Postma, Proc. K. Akad. Wetensch. Amsterdam, 1909, **12**, 186), but it cannot be asserted that this is ammonium hydroxide. If this compound were NH_4OH and it dissolved in water without decomposition it would produce, as will appear from what follows, a solution as strongly alkaline as, say, rubidium hydroxide. No properties of aqueous ammonia, however, compel belief in the existence of NH_4OH in solution.

The conclusion that this compound does not exist in solution in appreciable quantity is fortified by the fact that ammonium is an extremely strong basic radicle. It has been shown by Tutton (Chem. Soc. Trans., 1903, **83**, 1049), and by J. Ferguson in conjunction with the author (Chem. Soc. Trans., 1922, **121**, 1406), that in the series of the alkali metals ammonium occupies a very high place near to cæsium. It is unlikely, therefore, that in a N/100 solution of ammonia any but a minute quantity of undissociated NH_4OH exists, so that if this compound is formed at all this can only be because the interaction of its ions necessarily produces it. The difference between NaOH and NH_4OH in equilibrium with their ions in solution thus becomes clear : it is that the equilibrium is approached from opposite ends in the two cases. In the case of NaOH the ions are separated from the individual compound by dissociation ; in the case of NH_4OH the compound, if formed at all, is produced by the association of its ions. That is why we know that NaOH exists, but cannot affirm the existence of NH_4OH.

It may be objected, however, that progressive increase in relative concentration of $\overset{+}{N}H_4$ and $\overset{-}{O}H$ ions on dilution of ammonia solution appears to point to the progressive ionisation of previously existing NH_4OH. The alternative explanation is, however, simpler, viz. : that the more effective distribution of NH_3 molecules amongst the rarely occurring hydrions of water, or stated otherwise, the relative increase of hydrion concentration, when the solution is diluted, causes a relatively greater proportion of ammonium and hydroxide ions to be produced, *i.e.*, the effective mass action of water may be supposed to cause the direct formation of these ions rather than their indirect formation from NH_4OH.

Ammonia then forms so weak an alkali because it has little power of combining with the hydrions of water and there is no other means by which it can form alkali. This disability it shares with the alkylated ammonias so far as reacting with water is concerned. The case of tetraethyl ammonium hydroxide is quite different. This base does not depend for its formation upon a reaction with the hydrions of water, since it is produced by the interaction of tetraethylammonium iodide and moist silver oxide. It resembles sodium hydroxide in properties, and therefore when dissolved in water produces a hydroxidion concentration approaching that of the strong caustic alkalis. Thus an explanation is given of the great discrepancy in strength between $N(C_2H_5)_4OH$ and the three bases which follow it in the table.

That mono-, di-, and tri-ethylamine are about seven times as strong as ammonia shows, however, that the substitution of alkyl groups for hydrogen atoms increases the power of reaction with the hydrions of water. Nevertheless it by no means follows that the alkylammoniums are stronger basic radicles than is ammonium itself. There is little possibility of their being much stronger, since the ammonium ion itself approaches the cæsium ion in strength. Further evidence on this point is desired.

It may be pointed out in this connexion that ionic strength and ionic stability are not necessarily associated together. Ammonium is an exceedingly powerful ion, but it is not an exceedingly stable one. Ammonium salts are not very hydrolysable, but they appear to be more hydrolysable than the corresponding sodium salts. This is because the ammonium ion breaks down into ammonia, which leaves the solution on boiling, and hydrion, which produces acidity. This reaction is not really hydrolysis, since water does not act chemically on the salt.

The conclusions reached concerning ammonia and its derivatives may be applied to analogous compounds of non-metals other than nitrogen, *e.g.*, to the phosphonium, sulphonium and iodonium bases.

Phosphine is not basic enough to appropriate the hydrions of water to yield an alkaline solution; therefore it is concluded that phosphonium hydroxide does not exist. Phosphonium iodide, formed by the union of phosphine and hydrogen iodide is decomposed by water with the separation of hydrions thus :—

$$PH_4I \rightarrow \overset{+}{PH_4} + \overset{-}{I} \rightarrow PH_3 + \overset{+}{H} + \overset{-}{I}$$

The alkyl phosphines are more basic than phosphine itself, but less basic than the corresponding ammonia derivatives. Thus no alkylated phosphine appropriates hydrion from water to produce an alkaline solution; and the salts of the primary, but not those of the secondary or tertiary phosphines are decomposed by water. Tetra-alkylphosphonium hydroxide, formed by the interaction of the iodide and moist silver oxide is strongly basic and alkaline. Thus phosphine and phosphonium reproduce on a lower level of basic strength the properties of ammonia and ammonium.

With hydrogen sulphide the boundary line between base and acid has been passed; for instead of appropriating hydrions from water hydrogen sulphide in aqueous solution adds to their number. It is not surprising therefore that whilst the alkylated phosphines combine with acids to form salts, the alkylated sulphines, *e.g.*, C_2H_5SH and $(C_2H_5)_2S$, do not. Nevertheless the completely alkylated sulphonium halides $(C_2H_5)_3SX$, react with moist silver oxide, like the analogous ammonium and phosphonium halides to produce alkaline hydroxides, *e.g.* $(C_2H_5)_3SOH$. Thus a condition is reached in the case of sulphur in which hydrion cannot be appropriated in aqueous solution, even although it is present in the state of concentration furnished by a mineral acid. That an alkyl group can, however, be attached to the sulphur atom under other conditions emphasises the contrast between completely alkylated basic radicles and those in which one or more hydrogen atoms occur in place of alkyl groups.

The iodonium bases, *e.g.* $(C_6H_5)_2IOH$, show the extreme case of the phenomena under consideration, since hydrogen iodide, to which these are related, is, unlike hydrogen sulphide, an acid of maximum strength.

It is surprising that these bases contain aryl rather than alkyl groups, but this circumstance depends primarily on the power possessed by phenyl and other aromatic iodides to form additive dichlorides.

That $(C_6H_5)_2IOH$, formed in an indirect and unique manner, is actually alkaline, is the last and most striking example of the power of nonmetals to form basic radicles when attached to hydrocarbon residues. That this base is not stable enough to be isolated in the solid state is not to be wondered at. What are the relative basic strengths of the radicles :—

$$[\overset{+}{N(C_2H_5)_4}],\ [\overset{+}{P(C_2H_5)_4}],\ [\overset{+}{S(C_2H_5)_3}],\ [\overset{+}{I(C_6H_5)_2}],$$

is a question upon which information would be enlightening.

PASTEURISATION OF MILK

By JOSEPH RACE,
Formerly City Bacteriologist and Chemist, Ottawa

In this article it is proposed to review briefly the scientific evidence as to the effect of pasteurisation upon milk. Pasteurisation, as applied to milk, has, in the past, been a very indefinite term, but now that the new regulations are in force the term is taken to mean the heating of milk to 145° F., and holding at that temperature for thirty minutes.

CHEMICAL

Various claims have been made that chemical changes are produced during pasteurisation, and that they are the cause of various intestinal and nutritional disturbances.

The effect of heat upon the chemical constituents of milk was investigated by Rupp in 1913, and his conclusions were :—(1) Milk pasteurised by the holder process at 145° F. for 30 minutes does not undergo any appreciable change: (2) The soluble phosphates of lime and magnesia do not become insoluble; at 155° F. the quantity of phosphoric acid, lime, and magnesia in the serum of both raw and pasteurised milk is practically the same: (3) The albumin does not coagulate at 145° F., but at 150° F. 5·75 per cent. of the albumin is rendered insoluble; at 155° F. the quantity increases to 12·75 per cent., and at 160° F. it amounts to 30·78 per cent.: (4) The temperature required for coagulating the casein by rennin is slightly less in milk pasteurised at temperatures up to 149° F. than it is in raw milk; at 158° F. there is a slight retardation, whilst at 167° F. the time has almost doubled: (5) The acidity as determined by titration is slightly diminished in pasteurised milk.

The results obtained by the writer confirm the observations of Rupp that pasteurisation slightly reduces the acidity as determined by titration with phenolphthalein as indicator. A series of several hundred samples indicated that the average reduction was approximately 10 per cent., a value which is somewhat less than the normal variation in raw milk. The loss of acidity is due to the loss of carbonic acid gas (Van Slyke and Baker) during pasteurisation, and the amount is determined by the nature of the plant. Closed heaters and coolers will tend to re-absorption of the gas given off during heating.

Milk fat is comparatively sensitive to heat, and if the pasteurising temperature rises above 145° F. the physical condition of the fat globules is altered. At 150° F. a partial coalescence of the fat globules occurs, with the result that the cream rises rapidly in the finished product, but is diminished in volume. At 145° F. the cream line, *i.e.*, the percentage of cream, is unaltered. This fact is of the highest importance commercially, because a diminished cream line tends to reduce the value of the finished product.

TASTE

The flavour of milk is not changed by heating to 145° F. for thirty minutes. At a few degrees above 150° F. a slight " skin " is formed on the surface, oxidation occurs, albumin is precipitated, and the flavour is altered to that characteristic of heated milk.

ENZYMES

Numerous enzymes have been detected in milk, the chief ones being amylase, catalase, lipase, galactase, oxidase, peroxidase, and reductase. The nature and character of these bodies at once suggest that their origin is in the blood, and the epithelial and other cells derived from the cow. Some unpublished results of the writer indicate that the amount of reductase in milk is proportional to the butter fat content. Enzymes usually increase with the cell content, and it is possible that the cell content in normal milk is partially determined by the fat content. Inflammation in the milk cistern, secretory ducts, and teats increases the number of leucocytes in the milk and also the quantity of enzymes.

The presence of enzymes in milk may be considered as adventitious, and their effect upon it and the role that they play during digestion as hypothetical. Their activity is so small compared with that of the normal secretions of the alimentary tract as to be a negligible quantity. In view of the possibility that this may be incorrect, whatever data are available as to the effect of heat upon enzymes have been collected in Table I. :—

TABLE 1

Effect of Heat on Enzymes in milk

Enzyme	Authority	Weakened At temp. C.	Weakened in mins.	Destroyed At temp. C.	Destroyed in mins.
Galactase ..	Babcock and Russell	65–70	10	76–80	
	Von Freudenreich	65–70	30	75–80	
	Hippius	65	30		
Amylase ..	Koning			68	30
	Hippius			75–80	
	Race	68	30		
Lipase ..	Gillet			65	
Lactokinase	Hougardy ..			75	30
Oxidase ..	Marfan			79	
	Hippius			76	
Peroxidase	Wender			83	
	Schardinger ..			80	
	Ostertag			80	
	Lythgoe	70	30	75	30
	Race	68	30	73	30
Catalase ..	Von Italic ..			over 70	
	Lythgoe	65	30	70	30
	Race	68	30	71	30

When the difference between the samples experimented with is taken into consideration, together with probable variations in the acidity, the above results are very concordant and show that there is no reduction in the enzyme content when milk is heated below 150° F. for thirty minutes.

BACTERIOLOGICAL

Bacteriology, as a science, is much less exact than chemistry, and the results obtained by its application are less definite and more open to controversy. The more or less empirical methods employed by bacteriologists make it difficult, if not impossible, to compare the results obtained by different workers; and the problem is complicated further by the interpretation placed upon pasteurisation in the past. For the present purpose it will suffice to consider only those results obtained in recent years in which the heat treatment is definitely stated.

One of the most serious criticisms of pasteurisation has been the allegation that it interferes with the normal process of souring. Russell and Hastings state :—" The lactic bacteria do not form spores and hence are easily killed if milk is heated. If milk is pasteurised and subsequently kept free from lactic bacteria it will not sour but will putrify, due to the development of the spores not killed by heating."

This phase of the problem was the subject of a very considerable amount of experimental work in the Dairy Division of the U.S. Department of Agriculture, and the results, briefly stated, are that pasteurisation of milk at 145° F. for thirty minutes reduces the total number of bacteria of all kinds, but increases the relative proportion of acid-forming organisms. These results were confirmed in the writer's laboratory in Ottawa, in 1914, when a series of commercial samples gave the following proportion of acid and proteolytic (protein splitting) groups.

	Percentage of Groups Proteolytic	Percentage of Groups Acid forming
Raw milk	12	35
Pasteurised milk ..	2	49

The difference between these results and those of earlier workers is explained by the variation in the heat treatment. When milk is heated to 100° C., the vegetative forms of organisms are destroyed and only the spores remain. As spore formers are usually putrefactive and non-acid forming such milk would putrefy and not sour in the normal way. The treatment at 145° F. does not destroy the whole of the non-sporing forms, but merely reduces the number to a relatively low figure. These develop later and produce normal souring. The results obtained by Ayers and Rupp, and the writer, indicate that the acid-producing organisms are more resistant to heat than are, in general, the protein-splitting ones. A few typical examples from the writer's results are given in Table II. :—

TABLE II

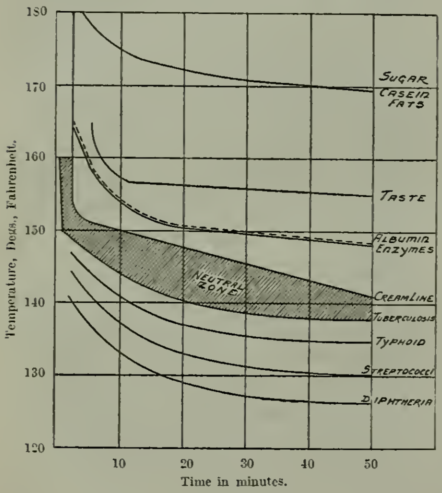
Effect of Treatment at 145° F. on Milk Organisms

Duration of treatment in minutes	Acid producing organisms 1	2	3	Proteolytic organisms 4	5
0 ..	6,100,000	80.000.000	71,000,000	15,000,000	40,000,000
10 ..	2500	100,000	150.000	110	700
20 ..	127	400	1400	10	40
30 ..	96	380	720	4	16
Percentage undestroyed	16×10^{-4}	$4{\cdot}7 \times 10^{-4}$	10×10^{-4}	$0{\cdot}3 \times 10^{-4}$	$0{\cdot}4 \times 10^{-4}$

It is important to note that the bacterial count was not reduced to zero per c.cm. with any of the organisms used.

Further corroborative evidence was obtained during the examination of 98 samples of pasteurised milk by the fermentation test. Of these, 55 to 60 per cent. gave a smooth gelatinous curd due to acid-forming organisms, whilst in 35 per cent. of the samples the number of organisms was too small to produce a curd within the period of incubation. Not a single sample produced a peptonised curd and the proportion of rennet curds was exactly equal to that in certified milk (grade " A ") during the same period.

The infectious diseases that are generally considered to be transmitted by milk are tuberculosis, typhoid fever, diphtheria, scarlet fever, and septic sore throat. It is generally conceded that the organisms causing these diseases are, with the possible exception of B. tuberculosis, quite destroyed or so reduced in number as to render the milk no longer infective. The great majority of sanitarians consider that B. tuberculosis is also either destroyed or so attenuated that it can no longer produce lesions, but in view of the fact that Delépine was able to demonstrate the presence of B. tuberculosis in dried milk the matter cannot be regarded as finally settled. A consideration of the results shown in Table II is of assistance in this connexion. These show that, when there is a massive infection with any organism a small proportion escapes destruction and can be found in the heated product. Normally, the number of disease-producing organisms found in milk from a mixed herd would be comparatively small, and treatment at 145° F. for thirty minutes would insure their practical destruction. It is conceivable, however, that a massive infection may occur and sufficient organisms may survive the treatment to produce typical lesions in guinea pigs. Whether it is possible that a sample that will produce lesions in guinea pigs may not produce a similar effect in children cannot be answered. In the former case the intra-peritoneal or the subcutaneous method of injection is used, and there can be no doubt that the introduction of the needle must tend to lower the natural resistance of the tissues involved. With children the introduction as food is much less severe and there is no artificial impairment of the natural resistance.



All are agreed that pasteurisation reduces the infectiveness of milk, and even if in, perhaps, one case in a thousand, the protection is not absolute, the method must still be considered satisfactory.

VITAMINS

The discovery of accessory food substances or vitamins is of comparatively recent date, and although a large amount of work has been done on this branch of biochemistry and a number of very important results have been obtained, there is still much to be accomplished before they can be classified into a rational scheme. Like the enzymes, the pure substances have not been isolated and it is only by their nutritional properties that they can be detected.

For the present purpose it is proposed to classify the vitamins in accordance with the modified scheme of Drummond adopted by Bywaters in the Report of the Progress of Applied Chemistry, Vol. V, and designate the " fat soluble vitamin " involved as a causative factor in rickets as vitamin " A " ; the " antineuritic " or " water soluble vitamin " as vitamin " B " ; and the " antiscorbutic vitamin " as vitamin " C."

Practically nothing has been published as to the effect of low temperature pasteurisation on the vitamins in milk, and until the investigations on this phase, which the writer understands are now being made at the instigation of the Ministry of Health, are published, the subject must be regarded as *sub judice*.

The available data indicate that heating to 145° F. for thirty minutes will have little or no effect upon the vitamins. Daniels and Loughlin found that heated milk was deficient in vitamin " A," but if the precipitate of phosphates and albumin were added as a colloidal suspension, the results were equal to those with raw milk. At 145° F. there is no precipitation, and it can be inferred that there is no loss of vitamin " A " at this temperature.

Vitamin " B " appears to be more resistant to heat than vitamin " A," and should not be diminished by pasteurisation. With vitamin " C " the results are somewhat conflicting. Dried milk made by the spray process was found by Jephcott and Bacharach to contain less vitamin " C " than that produced on steam rollers, while Hume found that full cream sweetened milk, which is evaporated at a low temperature under reduced pressure, was equal to raw milk in antiscorbutic properties.

The possible partial destruction of vitamins during pasteurisation should be considered in conjunction with a partial deficiency in raw milk. If, as some feeding experiments indicate, raw milk may be deficient in vitamins, the addition of fruit juice is always desirable whether raw or pasteurised milk is used, and the possible partial destruction of vitamins during heating becomes of no practical importance.

The general effect of pasteurisation upon milk has been diagrammatically expressed by Dr. North of New York, and his diagram, slightly modified in accordance with more recent data, is reproduced. This indicates that the neutral zone is so small as to call for extreme care during the pasteurisation of milk. Temperature has to be carefully controlled and in the best plants recording thermometers are in use.

Novel Method of Communicating the Results of Research

The British Non-Ferrous Metals Research Association has evolved a rather ingenious way of communicating the results of its research investigations to its members. Lectures are arranged at one or more centres to which as a rule only Members of the Association are admitted. Two objects are thus served, firstly, early confidential communication of the results of the research is assured to those who have given it financial support, and secondly, the investigator gets into close and immediate contact with that section of the industry chiefly interested in his work. In this manner the future direction of work and its relative practical importance are subjected to the consideration of the investigator and the industry.

The Non-Ferrous Metals Research Association is at present engaged on some ten investigations. Dr. W. Rosenhain, F.R.S., has already reported on the investigation on copper, carried out for the Association by Dr. D. Hanson and others at the National Physical Laboratory. Another large attendance of Members was occasioned by the lecture on "The Cause and Prevention of Red Stains on Brass," by Mr. E. A. Bolton, M.Sc., describing work on this troublesome difficulty which he is carrying out at Birmingham University. The Association has now arranged a third lecture to be given, both in Birmingham and Sheffield, by Mr. Dartrey Lewis, M.Met., on his work on "Materials used for the Abrasion and Polishing of Metals." In view of the wide interests covered, a limited number of tickets is being issued to non-members. The Birmingham lecture will be held on February 26, at 7.30 p.m., and the Sheffield lecture on February 23, at 2.30 p.m., and tickets, so far as space permits, can be obtained from the Association's offices, 71, Temple Row, Birmingham.

CALCIUM CARBIDE INQUIRY III

By SIR WILLIAM J. POPE

The Synthesis of Organic Compounds

The modern student of organic chemistry does not comprehend without effort the attitude of his great predecessors towards the larger aspects of the subject. Charles Gerhardt, speaking of his new classification of organic substances, said: "I show therein that the chemist does the opposite of what is done by living nature: that he burns, destroys and proceeds analytically: that vital force alone acts synthetically and rebuilds the edifices shattered by chemical forces. A satisfactory classification can therefore only be founded upon the decomposition products of chemical compounds" (Comptes rendus, 1842, **15**, 498). A little later Berzelius observed that "in living nature the elements seem to obey laws quite different from those which hold in inorganic nature. If we could discover the cause of this difference we should hold the keys to the theory of organic chemistry; but the theory is so well hid that we have no hope of discovering it, at least, at present" (Lehrbuch der Chemie, 1849, **5**, p. 1).

The development of synthetic methods in organic chemistry removed the obstacle to progress indicated in the foregoing quotations; the importance of such methods was, however, but slowly realised. The term "synthesis" was not applied chemically by German workers prior to 1850; Kopp speaks of Wöhler's synthesis of urea as the "artificial preparation" of that compound (Geschichte der Chemie, 1847, **4**, 381) and Gmelin notes that "it appears not impossible that we shall some day be able to form artificially many, if not all, of the organic compounds which occur in nature" (Handbook of Chemistry, 1852, **7**, 42). John Dalton has a chapter "On chemical synthesis" (A new system of chemical philosophy, 1808, **1**, 211); see also P. Shaw, Chemical Lectures, 1755, 179. Stas, however, figures the apparatus by aid of which he determined the atomic weight of carbon by the "synthesis of carbonic acid" (Bull. Acad. Belg., 1849, **16**, 9) and, a little later, Berthelot, the most distinguished of the early workers in the new field, clearly defined the purpose of synthetic organic chemistry.* He stated that "the word synthesis refers to the formation of an organic substance from the elements: carbon, hydrogen, oxygen, nitrogen, etc.; it is also applied to the preparation of an organic compound from other compound substances less complex than the product to which they give birth" (Leçons de Chimie, 1861, p. 167).

Berthelot thus conceived (1) a broad definition of a synthetic organic compound and (2) one more limited, designed to meet the needs of synthetic organic chemistry as a rapidly developing science. These two definitions may be thus stated :—

---

* I spoke inadvertently of oxalic anhydride as being well known (this J., 5, line 46); of course, this compound has not yet been prepared.—W. J. P.

(1) A synthetic organic compound is one which is produced by the direct combination of carbon with another element or with other elements.

(2) A synthetic organic compound is a carbon compound which is produced from other compounds of more simple molecular composition.

The distinction between the definitions involved in the two sections of Berthelot's statement was elaborated by Lieben (Annalen, 1868, **146**, 205), who explained very lucidly his reasons for restricting the term synthesis to those operations in which carbon atoms become actually joined together. Eminent modern workers in general organic chemistry still use the word in the two senses, as is evident from the following definitions.

(3) "The term 'synthesis' as used in organic chemistry is generally assumed, if not explicitly stated, to mean the building up of a carbon compound from compounds of lesser complexity. If the simpler molecule is capable of being produced directly from its elements the synthesis is said to be complete" (Meldola, The Chemical Synthesis of Vital Products, 1904, **1**, p. 9).

(4) "By the synthesis of a carbon compound is understood its building up from the elements or from such carbon compounds as can be produced from the elements" (Richter, Chemie der Kohlenstoffverbindungen oder organische Chemie, 1909, **1**, p. 85).

Organic chemists who deal more specifically with the synthetic methods of organic chemistry generally adopt the second Berthelot conception as the basis of their definition, thus :—

(5) "The idea of 'synthesis' in chemistry has a very variable range. In its widest sense it is applied to the preparation of any specific complex substance from simpler ones ; otherwise by synthesis is meant the production of naturally occurring chemical compounds by artificial means—a very narrow conception of the term. In the following pages by synthesis will be understood those methods of producing carbon compounds in which carbon atoms, which are either free or are not directly combined with each other, become joined together" (K. Elbs, Die synthetischen Darstellungsmethoden der Kohlenstoffverbindungen, 1889, **1**, p. 3).

(6) "The idea of 'synthesis' in organic chemistry is very differently understood. By synthesis is understood, on the one hand, only the direct building up of organic compounds from their elements, and on the other, all those methods for producing organic compounds in which carbon atoms, which were previously not combined or were not combined together, become linked up one with the other" (Posner, Lehrbuch der synthetischen Methoden der organischen Chemie, 1903, p. 2).

The distinct significations thus attaching to the term synthesis as applied in organic chemistry may be referred to as (1) that of a complete synthesis, in which a carbon compound is produced by the combination of elementary carbon with other elements, in one or several stages, and (2) that of a structural synthesis, in which carbon atoms previously not joined become so combined together. It would probably be best to adopt the nomenclature described by J. B. Cohen (Organic Chemistry, 1920, **1**., p. 175) and speak of the synthesis of a complex hydrocarbon radicle as a condensation. If Lieben's view is rigidly applied, the production of methane from carbon and hydrogen and of formic acid from sodium hydroxide and carbon monoxide have to be excluded from the category of synthetic processes. It will be seen, however, that the preparation of calcium carbide from lime and coke is a synthetic process according to all the definitions referred to above.

PROOF THAT CALCIUM CARBIDE IS A SYNTHETIC PRODUCT

The production of calcium carbide in the electric furnace from lime and coke is generally represented by the equation :—

(*a*) $CaO + 3C = CaC_2 + CO$.

The study of this reaction, in which three components are present in four phases, has shown that two balanced reactions are involved ; these are represented by the equations :—

(*b*) $CaO + C = Ca + CO$

(*c*) $Ca + 2C = CaC_2$.

Reactions (*b*) and (*c*) have been investigated quantitatively (Rothmund, Zeits. f. anorg. Chem., 1902, **31**, 136 ; Rudolphi, ibid, 1907, **54**, 170 ; Briner & Kuhne, Journ. chim. phys., 1914, **12**, 432) ; it will be seen that equation (*a*), expressing the overall production of calcium carbide from lime and coke, is the algebraic sum of equations (*b*) and (*c*). The production of calcium carbide from calcium and carbon, which occurs readily when the metal is heated before the blowpipe on a carbon block (Knecht, Ber., 1908, **41**, 498), in accordance with equation (*c*), is reversible. Calcium carbide decomposes slowly into calcium and carbon even at 1050° C. and more rapidly at higher temperatures (Botolfsen, Ann, chim., 1922, **18**, 39). Reaction (*c*) and its reversal are thus essential steps in the formation of calcium carbide from lime and coke ; the manufacture of calcium carbide thus conforms as a synthesis to the wider definition (1).

Further, the elementary carbon which yields calcium carbide with the metal, in whole or in part passes through the stage of carbonic oxide, the molecule of which contains but one carbon atom. It follows that, in the formation of calcium carbide, carbon atoms not previously joined together combine to produce the acetylenic hydrocarbon radicle which has been already shown to be present in the carbide ;

the whole process is, therefore, a structural synthesis in the sense of definition (2).

The work of Guntz (Comptes rendus, 1896, **123**, 1273; Bull. Soc. Chim., 1896, [3], **15**, 756) is of interest as bearing upon the fact that two previously unjoined carbon atoms become linked together during the formation of calcium carbide. He shows that lithium, heated at about 700° in acetylene or ethylene, reacts as follows:—

$$C_2H_2 + 4Li = Li_2C_2 + 2LiH \text{ and}$$
$$C_2H_4 + 6Li = Li_2C_2 + 4LiH,$$

whilst, in methane at a low red heat no trace of lithium carbide is produced. At these low temperatures of reaction the carbide is produced only from a hydrocarbon which already contains a chain of two carbon atoms; it is not formed from a hydrocarbon which does not contain this linkage.

PROOF THAT CALCIUM CARBIDE IS A SYNTHETIC ORGANIC COMPOUND

It is now submitted that calcium carbide has been proved to be an organic compound on the following grounds:—

(*a*) It is a compound of carbon, further,

(*b*) It is the calcium derivative of acetylene and contains the acetylenic hydrocarbon radicle, $-C{\vdots}C-$.

Also, this organic compound is proved to be a synthetic substance, because

(*c*) It is produced from its component elements in its ordinary process of manufacture, and, further, that,

(*d*) In its manufacture a condensation occurs in which two atoms of carbon become joined together.

It is of interest to note that the Referee's recent decision (J., 1922, **41**, 556 R), to the effect that oxalic acid manufactured by the formate process is a synthetic organic chemical, is paraphrased in the above conclusions. He stated that "there is no doubt that oxalic acid is an organic body which can be built up from its elements. The process begins with the use of carbon, the number of carbon atoms in the molecule is increased and the molecule becomes heavier. The molecular construction contains two atoms of carbon linked together. Although in practice the first step in building up is the combining of carbon monoxide and caustic soda, both these substances can be obtained from their elements." The same reasons are given for two diametrically opposed decisions.

GENERAL CONSIDERATIONS

In his decision on the calcium carbide case the learned Referee noted the complainants' contention that the words "synthetical organic chemical" have a technical meaning and stated that, if this were the case, it was his duty to give the words that meaning; this is a point of law which can excite no criticism.

The obvious method for eliciting an answer to the question here indicated is that which has been used in this and the previous articles. A collection has to be made of definitions of the terms "organic" and "synthetic," as presented by those important contributors to organic and synthetic chemistry who have had to think the matter carefully out, and a judgment passed upon the balance of opinion. As I have shown, no organic chemist of repute gives a definition which does not include calcium carbide as an organic compound, whilst the term synthetic, according to all our classical writers, is entirely applicable to the manufacture of calcium carbide. The evidence is, in fact, all on the one side.

During the hearing, however, this method was not used. A number of gentlemen were examined and cross-examined concerning their personal impressions. Obviously, no attempt was made to establish a documentary case and a decision was given on what was practically a desultory conversation, a large part being taken by an entirely erroneous translation of a very authoritative definition. Sir Arthur Colefax, one of the leading counsel engaged in the hearing, and an authority worthy of the utmost respect, says that I am in error in making this last statement (this J., 75); but the point may well be left to the judgment of members of the Society of Chemical Industry after they have read the text of the decision (J., 1922, **41**, 46 R).

Those responsible for the presentation and the contest of the case presented the Referee with no adequate statement on the question of definitions, nor did they place before him the large amount of experimental evidence which demonstrates calcium carbide to be the calcium derivative of acetylene.

In the present controversy, Sir Arthur Colefax and I start from different premisses and with different objects. I inquire whether the evidence contained in the vast stores of knowledge which constitute modern organic chemistry proves calcium carbide to be a synthetic organic compound; the learned counsel asks whether the sketchy outline of the subject placed before the Referee justified this gentleman in his decision. Both questions must be answered in the affirmative. Calcium carbide is a synthetic organic chemical but the complainants did not produce the available evidence in proof thereof. Sir Arthur is needlessly disturbed by the thought that I have been lacking "in fairness to the learned Referee" by my observations that "the proceedings degenerated into an orgy of misrepresentation and misinterpretation" and that "these Board inquiries have become ridiculous farces played to the shame of British methods of legal procedure." I am well aware that the trivialities which he describes sententiously as "the evidence" were received with great decorum, although they would have excited hilarity if produced before an assembly of chemists.

The difference in standpoint between Sir Arthur Colefax and myself is emphasised by the question which he puts to me (this J., 76) as to whether I think that the learned Referee would have been helped by the appointment of an assessor who was "one of the eminent gentlemen who gave it as their opinion that calcium carbide was not a synthetic organic compound." The significance of this question becomes apparent when it is noted that the learned Referee in the calcium carbide inquiry was selected from amongst the advocates—from the distinguished society of King's Counsel formed by Sir Arthur Colefax and his colleagues—and that no one would ever dream of suggesting that any of these gentlemen, when transferred from an advocative to a judicial function, would act otherwise than with strict impartiality. The question suggests that virtue resides only in the practitioners of the law; it implies that all will be well provided that "the evidence," no matter how insufficient it may be, is presented and received with due ceremony, and gravely adjudicated upon. I see no reason for anticipating that either of the distinguished organic chemists who gave evidence for or against the complainants would have shown any partiality had he been appointed to aid the Referee as assessor; I am quite sure that such an assessor would have warned the Referee that "the evidence" placed before him was so fragmentary as to be fictitious, that he was being misled, and that he would do well to call for facts upon which to base a decision.

In these articles I claim to have proved that the evidence to the effect that calcium carbide is a synthetic organic compound is overwhelming. The case is a very simple one, and if my contention is correct it follows that the legal profession has failed in its duty by dealing so perfunctorily with the question submitted to it that an indefensible decision has had, perforce, to be pronounced.

The Schedule to the Safeguarding of Industries Act

The Safeguarding of Industries Act, 1921, was designed with the laudable purpose of fostering many new expansions of British industry and of shielding these from destruction by "dumping" from the Continent. So far as the layman can judge the text of the Act is straightforward and free from ambiguity. The frequent protests which have been made in the Courts and in the Press have mostly been directed, not against the text of the Act, but against the interpretative schedule, and the list of articles chargeable with duty under the Act; these latter are presumably the contribution of the Board of Trade.

The last paragraph of the schedule to the Act may be here more particularly criticised; this specifies as "Goods chargeable with duty" the following:—

"All synthetic organic chemicals (other than synthetic organic dyestuffs, colours, and colouring matters imported for use as such, and organic intermediate products imported for their manufacture), analytical reagents, all other fine chemicals (except sulphate of quinine of vegetable origin) and chemicals manufactured by fermentation processes."

If the declared function of the Board of Trade were the instigation of litigation in the chemical industry it could hardly have acted more efficiently than by such an insertion into the Act. The paragraph intercalates chemical scientific terms of precise meaning and commercial terms of a qualitative nature in such a manner that the whole carries no collective meaning. It can be proved that certain substances are "synthetic organic chemicals," although the use of the unsystematic word "chemical" promotes obscurity, but the expression "fine chemical" is meaningless in a legal document; one witness, indeed, observed that he recognised a "fine chemical" by instinct (this J., 1922, **41**, 555 R).

This concluding paragraph of the explanatory schedule could easily have been drafted in a form entirely free from ambiguity; in such a way, in fact, that counsel's opinion could state very definitely whether an application for inclusion or exclusion of a specific material would or would not succeed. It would not have been passed in its present form had it been submitted to a body of competent scientific and technological chemists for criticism and suggestions. The Association of British Chemical Manufacturers will no doubt agree with this statement; it is to be hoped that this organisation will urge the awful example of the Safeguarding of Industries Act in Government circles and will succeed in making impossible a repetition of this bungle.

ASSOCIATION OF TAR DISTILLERS

Mr. S. A. Sadler, of Middlesbrough, presided at the dinner of the above Association at the Hotel Russell, London, on the 20th inst. About a hundred were present, including Dr. C. C. Carpenter, Dr. H. Butler, Messrs. Bower, Waugh, Robinson and Woolcock. Dr. Carpenter, in a graceful speech, explained how tar had enabled dustless and waterproof roads to be made, and he considered the manufacturers and distillers of tar would always be able to adapt their methods to changing conditions. Mr. E. Shrapnell-Smith contrasted modern roads with those existing in the early days of motoring. He considered the roads in this country were now as good as those in any other.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

THE VISIT OF THE KING to the British Industries Fair on Monday last, coincided with the opening of the Fair. I thought this a marked improvement on the arrangements made in previous years. It not only gave the Fair a good send-off but compelled each exhibitor to have his exhibit ready before the Fair opened. The Chemical Section was, as last year, in the first hall, as one entered at the Uxbridge Road entrance. There were not quite as many firms exhibiting as last year, but those who were exhibiting occupied a larger space. The management of this section was again in the hands of the Association of British Chemical Manufacturers, and both in the individual stalls and in the general layout I thought there was a marked improvement. But how stereotyped and ugly exhibition stands are. They are only there for a fortnight, it is true, and this may be urged as an excuse, but I hope something much more distinctive will be done at Wembley in 1924. A new feature of the Fair was the presence of the British Chemical Plant Manufacturers' Association in close proximity to the Chemical Section, as befitted a body which is an offshoot of the Association of British Chemical Manufacturers. His Majesty spent some time in the Chemical Section and seemed very interested in everything which was shown to him.

THE DEVELOPMENT COMMITTEE under the Dyestuffs Act appears to be very active just now. I hear that visits are being paid to each of the dyeworks in this country and that, already, a vast amount of information has been collected. Very little is heard as a rule about this Committee. It could not get to work as early as the Licensing Committee because it has, in a sense, to derive its information from the Licensing Committee's reports and work on them. For some time the Licensing Committee acted also as an informal development committee, but now, I believe, each Committee does its own work, and there are a sufficient number of persons who are members of both Committees to secure there shall be no clashing. The present position of the British Dyestuff Industry is very different from what it was in 1913. In those days we used to import about 80 per cent. of the dyestuffs used over here and make only 20 per cent. Indeed, of this 20 per cent. a fair proportion consisted of mixtures made with foreign dyes. Now the position is exactly reversed, and we make 80 per cent. and import only the 20 per cent. Not a bad record after only two years' working of the Act. The record with regard to price is almost as good. I am told that the Development Committee have found that the average price per pound of British dyestuffs which was nearly four shillings and sixpence eighteen months ago has been brought down to something a little over half-a-crown.

THE HABIT OF SELF-DEPRECIATION is not easily abandoned by your true Briton, but we may yet not only be proud of this new industry, but may even say so. Hearing about the progress of the dyestuff industry put me on inquiry as to what developments had been made in the manufacture of British fine chemicals, and I was told equally reassuring news. There are twice as many persons engaged in this branch of chemical industry as there were in 1913. For every ton of fine chemicals we made in 1913 we are making two and a half tons to-day, and it is estimated that we are making fourteen times as many as we were in 1913. The range is certainly very much larger than it was, and I believe the purity of the British products leaves nothing to be desired. Prices of fine chemicals have also fallen considerably, and I was given some instances where they were now below the pre-war price.

IF THE MANUFACTURE OF FINE CHEMICALS is to be established in this country it seems to me that it will have to be undertaken in a very different spirit from that of ordinary commerce. It is a peculiar business. The variety of the products is legion ; the quantity of some of them required in a year is, perhaps, a few ounces. Yet they must be of great purity and always in stock. Not a very profitable business I should imagine. Nevertheless, for the credit of Great Britain, it has to be done. If it is possible to get the help of professors and teachers of chemistry it can be done, but, unfortunately, in some quarters this is not forthcoming. I heard an interesting story the other day of a certain school which, having obtained quotations for some fine chemicals from British firms, forthwith placed the order in Germany. A little later the head of the chemical department wanted some assistance and applied to a British chemical manufacturer for it. He got what he wanted, but not until the manufacturer had asked the teacher where he was going to find places for his students if he assisted the Germans to shut up the works of the British manufacturers. This appeared to open up a new line of thought to the teacher of chemistry. The effect of the trouble in the Rhur is now beginning to be felt in British chemical industry, particularly with regard to dyestuffs and fine chemicals. I can confirm the news in your Market Reports of last week. Business is better.

GIFT OF £100,000 FOR SCIENTIFIC RESEARCH

It is announced that the offer by Sir Alfred Yarrow of £100,000 to the Royal Society, to be used at the discretion of the Council of the Society in promoting scientific research, has been gratefully accepted by the President and Council. In his letter to the President of the Royal Society offering the gift, Sir Alfred Yarrow states that he desires to mark his sense of the value of research to the community, by offering the gift to be used as capital or income for the purposes of the Society as the Council may think fit. Sir Alfred Yarrow further suggests that the rules framed for guidance of the committee to be appointed to administer the fund should be reconsidered by the Council every tenth year so as to meet modern needs. Further, he prefers that the money should be used to aid scientific workers by adequate payment and by the supply of apparatus and other facilities rather than to erect costly buildings. Sir A. Yarrow's success as a pioneer in the design and construction of high-speed vessels, has not been attained without much research, and his gift to the Royal Society is one of several made for the public benefit.

INTERNATIONAL TABLE OF ISOTOPES, ETC. (1923)

The following tables and other matter are extracted from the first report of the International Commission on Chemical Elements appointed by the International Union of Pure and Applied Chemistry.

Atomic number.—A *chemical element* is defined by its *atomic number*, which represents the excess of positive over negative charges in the constitution of the atomic nucleus; theoretically, the *atomic number* represents also the number of electrons which rotate round the central positive nucleus of the atom. Each *atomic number* also represents the place occupied by the element in the Mendeleef Table. Of the various methods suggested to determine the *atomic numbers*, the most important consists in deducing them from the wave-lengths of the high frequency spectra by applying Moseley's law.

Elements (simple and complex). Isotopes.—If the above definition is accepted, each chemical element may be *simple* or *complex*, according as its atoms are all of equal mass or not. In the latter case, the element consists of as many *isotopes* as its *atoms* have different *masses*. A *complex* element is a *mixture of isotopes*. Three methods (J. J. Thomson, Aston, Dempster) have been devised to determine isotopes, the most important being that of Aston.

Notation.—The elements, simple or complex, are represented by the ordinary symbols. To indicate any particular isotope its atomic mass is written as an index to the right of the symbol representing the mixture. The expression "atomic mass" is reserved for isotopes or simple elements considered from the isotopic point of view. The expression *atomic weight* retains its usual meaning, and is applied to elements without consideration of their isotopic constitution. Thus, Cl^{35} indicates the isotope of chlorine having an atomic mass 35. This number represents the relative mass of its atom, the atom of oxygen (a simple element) being taken as 16.

Elements included in the Table.—The isotopes of lead which are the ultimate result of disintegration of radioactive elements, and the radioactive isotopes will only appear in the International Table of the radioactive elements. Only those elements appear in the Table of Isotopes which are recognised as simple, or are complex elements whose isotopes have been determined with sufficient certainty.

Provisional values.—Numbers in brackets are to be taken as provisional only.

In the above table T is the time in which the quantity of radio-element is diminished to one-half, a_0 is the range in cm. of the α-rays in the air at 0° C. and a pressure of 760 mm. of mercury and, under the heading "Radiation," the brackets ( ) indicate that the radiation is relatively feeble.

FORTHCOMING EVENTS

Feb. 24. The Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 3 p.m. "Atomic Projectiles," by Sir E. Rutherford.

Feb. 26. Institution of Mechanical Engineers, Storey's Gate, St. James's Park, S.W. 1, at 7 p.m. "Photo-Elastimetric Researches on Mechanical Engineering Problems," by Prof. E. G. Coker.

Feb. 27. British Science Guild, Mansion House, E.C., at 3.30 p.m. "Science and Education," by Sir J. J. Thomson.

Feb. 28. Royal Society of Arts (Ordinary Meeting), 18, John Street, W.C. 2, at 8 p.m. "Heat Resisting Glasses," by Prof. W. E. S. Turner.

Mar. 1. The Chemical Society, Burlington House, Piccadilly, W. 1, at 8 p.m. "Co-ordination Compounds and the Bohr Atom," by N. V. Sidgwick. "Silver Salvarsan," by W. H. Gray. "The Propagation of the Explosion-wave Through Gaseous Mixtures," by H. B. Dixon.

Mar. 1. The Institution of Electrical Engineers, Lecture Theatre, Savoy Place, Victoria Embankment, W.C. 2, at 6 p.m. Report on "Permissible Loading of British Standard Paper-Insulated Electric Cables," by S. W. Melsom and E. Fawssett.

Mar. 2. Society of Chemical Industry, *South Wales Section*, The Technical College, Cardiff, at 7.30 p.m. Annual Meeting.

Mar. 2. Society of Chemical Industry, the Textile Institute, 16, St. Mary's Parsonage, Manchester, at 7 p.m. Joint Meeting of the Manchester and Liverpool Sections. "The Progress of the Chemical Industry in Great Britain since 1914," by Dr. H. Levinstein. A luncheon has been arranged at the Queen's Hotel, Portland Street, Piccadilly, at 1 p.m. After the luncheon, a visit will be paid to the Bradford Road Gas Works, at 3 p.m.

Mar. 3. The Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 3 p.m. "Atomic Projectiles," by Sir E. Rutherford.

Mar. 5. Institution of Rubber Industry, Engineers' Club, Coventry Street, Piccadilly, W. 1. "Telegraph Cable Manufacture, Rubber and Gutta Percha," by H. Savage.

Mar. 6. Society of Chemical Industry. *Edinburgh and East of Scotland Section*, Hall of the Pharmaceutical Society, 36, York Place, Edinburgh, at 7.30 p.m. Annual Meeting.

Mar. 6. Society of Chemical Industry, *Birmingham and Midland Section*, the University Buildings, Edmund Street, Birmingham, at 7 p.m. "The Influence of Protective Colloids upon the Velocities of Chemical Reactions," by J. Newton Friend.

Mar. 6. Royal Photographic Society of Great Britain, 35, Russell Square, W.C. 1, at 7 p.m. "An Electric Indicator for Washing-troughs," by K. C. D. Hickman.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1923

In accordance with the provisions of Byelaw 68, Notice is hereby given that the annual general meeting of the Society will be held in Cambridge on Friday, June 21, 1923, at 11 a.m.

The programme of the proceedings will be issued later; meanwhile it may be stated that the following are among the provisional arrangements that have been made:—

Members attending the meetings unaccompanied by ladies will be accommodated with rooms in the colleges. Those with ladies will obtain quarters at the local hotels.

In addition to the address of the president, Dr. E. F. Armstrong, F.R.S., there will be a popular lecture by Sir Wm. Pope, K.B.E., F.R.S., an address by Dr. F. W. Aston, F.R.S., on Isotopes, and a lecture on Cambridge and its Colleges by Dr. Cranage.

The Society's Medal for 1923 will be presented.

The annual dinner of the Society (which ladies may attend) will be held, and a large number of Cambridge guests will be invited to it. Members and ladies may lunch in various college halls, and there will be no official lunch on this occasion.

Arrangements will be made for parties to visit the various colleges and laboratories. There will be a visit to Ely, and it is believed there will be a reception and a dance.

The meetings will last from Thursday to Saturday inclusive, and they will be preceded by those of the International Union of Pure and Applied Chemistry, which holds its annual meeting on Monday, June 18, and the following Tuesday and Wednesday.

Any of the Society's members desiring to attend the meeting of the International Union will be welcome.

All communications regarding the meeting should be addressed to the General Secretary, at the offices of the Society in London, until further notice.

J. P. Longstaff,
General Secretary

MEETING OF COUNCIL

The monthly meeting of Council was held on Friday, February 9, 1923, the President (Dr. E. F. Armstrong, F.R.S.) in the chair.

The President announced steps that were being taken to arrange for the Annual General Meeting, at Cambridge, on June 20, 21 and 22 next; and progress was reported in the preparation of a scheme for organising propaganda relating to chemical industries in connexion with the British Empire Exhibition, 1924.

The reports of the Hon. Treasurer, and of various committees of the Council, were discussed, and 31 new members (home 23, and oversea 8) were elected.

The Council renewed its grant of £100 to the Chemical Society towards the upkeep of its library during 1923. It may be useful to remind members that, as the result of an arrangement between the Chemical Society and the Society of Chemical Industry, members of the latter Society are entitled to use the library and borrow books from it on precisely the same footing as Fellows of the Chemical Society. The Council is gratified to know that its members who are not members of the Chemical Society are taking advantage of this privilege to an increasing extent year by year.

It was unanimously agreed to award the Society's Medal for 1923 to Dr. C. C. Carpenter, of the South Metropolitan Gas Co., a former President of the Society. It was also decided to ask Dr. Carpenter to give an address at the Annual General Meeting.

Dr. S. Miall was appointed the Society's representative to the Annual Congress of the Royal Institute of Public Health, which will be held in Scarborough in May.

Latham Research Fellowship

Mr. James Craik, M.A., B.Sc., whose appointment to this Fellowship was intimated in the *Journal* for October 31, 1921, page 384 R, resigned in August last, and a paper embodying the results of his work will be published in the *Journal* in due course. The Council has now approved the selection of Mr. Leslie Hall, B.Sc., A.I.C., to work in association with Dr. Dorée in the Research Laboratory of the Borough Polytechnic Institute on "The Constitution of Lignone and the Ligno-Celluloses." The research will be in continuation of the scheme of "Researches on Cellulose," IV (Cross and Dorée), and under the immediate supervision of Dr. Dorée.

NEWS FROM THE SECTIONS

LIVERPOOL SECTION

A meeting of the section was held in the Muspratt Lecture Theatre, Liverpool University, on February 16, Dr. J. T. Conroy in the chair. At the outset the chairman referred in feeling terms to the great loss the section had sustained by the death of Mr. Arthur Carey, a member of the section for many years and a past-chairman. A vote of sympathy was passed to Mrs. Carey and family. A paper was then read by Mr. R. B. Croad, F.I.C., A.R.T.C., on "Synthetic Tannins," in which he suggested that the name "synthetic tannins" should be replaced by "syntans" to avoid confusion with the synthetic products prepared by Emil Fischer and his school, as the term was not applied to any particular product.

A short history of syntans since the production of Schiff's esterified phenol sulphonic anhydride in 1873 up to 1920 was given. Analytical figures were given refuting Moellers' statements in the *Collegium* of 1913 with regard to the hydrolytic action of syntans on pelt. The small quantities of hide substance found in the liquors after tanning was due to soluble amino-acids produced in the lime-sulphide treatment of the hide. This was supported by experimental evidence. Various methods of producing syntans were summarised as follows:—(1) Aldehyde on hydroxysulphonic acid; (2) aldehyde on sulphonated hydrocarbon; (3) aldehyde on hydroxyaromatic compound using an acid condensing agent and the subsequent sulphonation of the dry resin; (4) formaldehyde and sodium bisulphite on an aromatic hydroxy compound; (5) formation of sulphones by the action of heat on sulphonated hydrocarbons; (6) sulphonation of coumarone resins and heavy tar oils.

The commercial method of production was discussed, and also the types of leather yielded by the products and points to be taken into consideration when carrying out the official method of tannin analysis. These points were exemplified by a piece of leather produced by a syntan said to be of British manufacture which gave a good tannin analysis, but on pelt gave a hard, cracky leather, more like dried pelt than anything else. The action of syntans on the pelt was discussed, and a chemical theory of their tanning action advanced based on experimental results. Experiments leading up to the taking out of B.P. 182,823 and 182,824 by Messrs. Harold M. McArthur and Co., Ltd., of Aintree, were described. Samples of leather produced under these patents, together with samples of leather produced by British, American and German syntan manufacturers were shown. All the samples shown were two years old and had been tanned at the same time and under identical conditions. Save for slight alteration in colour, those produced under the alkaline condensations described in B.P. 182,823 and 182,824 had kept their fullness and suppleness, whereas the other samples had gone off badly in colour, becoming thin and tinny and the grain cracky. A method of analysis of Glaubers salts in syntans was put forward, which was quick and, on the syntans tried, accurate.

A discussion followed in which Messrs. A. Morton, H. B. Stocks, R. W. Riding and E. Gabriel Jones took part.

GLASGOW SECTION

The Committee of the Glasgow Section has decided to offer an annual prize in the form of books (which may be selected by the successful candidates) to the value of £5, for original work carried out by Student Associates of the Section. The conditions of the award are laid down as follows:—

The candidate must be a Student Associate of the Glasgow Section of the Society, and must have paid his annual subscription. He must submit, before October 31, a thesis embodying the results of either (*a*) an original experimental investigation; (*b*) original theoretical work; or (*c*) an original application of theoretical work to some chemical process. He must state explicitly whether his thesis is wholly original, or has been guided by others. The results of his work must not have been published prior to being read before the Section. Joint papers by two or more Student Associates will be eligible for award, in which case if the same is approved by the Committee, the prize will be divided equally between the authors. The successful candidate will be required to read his thesis either in full or in abstract at one of the ordinary meetings of the Section, when it will be discussed by members.

EDINBURGH AND EAST OF SCOTLAND SECTION

The fifth ordinary meeting of the session was held in the Hall of the Pharmaceutical Society, Edinburgh, on February 13, Dr. H. E. Watt presiding. A paper on "Vitamins" was read by Dr. G. M. Findlay, Royal College of Physicians' Laboratory, Edinburgh.

After a historical review of the development of the subject, an outline was given of the properties of the various vitamins and their distribution in foodstuffs. The existence of the three vitamins, A, B and C, has now been fairly well established, and another growth factor known as "Bios" has been termed by Funk "vitamin D." This factor is found in liver and muscle and promotes the growth of yeast and bacteria. At the same time McCollum and his co-workers have applied the term "vitamin D" to the anti-rachitic factor which they have described as existing in cod-liver oil. Deficiency of vitamin B in a diet produces the disease known as "Beri-beri," certain symptoms of which in pigeons are similar to those of anoxæmia, however produced, and possibly point to some interference with the respiratory mechanism of the cell. In cases of experimental beri-beri, however, the amount of oxygen in the blood stream is above the normal, and administration of oxygen will not cure the disease. The addition of carbohydrates to the diet increases the rapidity with which the symptoms appear. This connexion between carbohydrate metabolism and vitamin B deficiency is further borne out by the fact that in avian beri-beri the glyoxalase content of the liver is below normal, and administration of vitamin B in such beri-beric cases is followed by an increase in the glyoxalase content of the liver. Animals fed on a diet deficient in vitamin A fail to grow and become highly susceptible to keratomalacia. Vitamin A deficiency also predisposes to bronchitis and broncho-pneumonia. There is evidently some parallelism between the content in butter and maize of vitamin A and that of lipochrome pigment. Green plants also contain more vitamin A than etiolated ones. Vitamin A is stored in the liver and sub-cutaneous fats, so that animals usually have a considerable reserve dependent on the amount of vitamin A in the food. Vitamins B and C are not stored to any extent. Vitamin C, a deficiency of which causes the development of scurvy, is more sensitive to the effects of heating in presence of air, and, in particular, is destroyed by heating in copper vessels. Many seeds like those of the pea and wheat, which contain only inappreciable amounts of this vitamin show a large increase in the amount on germination.

Recent work has shown that there is no relationship between deficiency of vitamin A and the development of rickets, but McCollum and his co-workers have demonstrated that cod-liver oil which has been deprived of its supply of vitamin A is yet able to prevent the onset of this disease, so that they have suggested that there is an anti-rachitic in cod-liver oil. Animals fed on a diet deficient in calcium and phosphates and containing as its source of fat some substance like cottonseed oil will develop rickets, but if to this diet is added a supply of cod-liver oil the animals will remain normal. An interesting fact is that a diet sufficiently low in phosphates to produce rickets under normal conditions will not do so if the animal is provided with only starvation quantities of the food, or if the animal is exposed to ultra-violet rays. Both starvation and exposure to ultra-violet rays produce an increase in the amount of inorganic phosphates in the blood stream. This is confirmed by the fact that there is a seasonal variation in the amount of phosphate in the blood of children examined in towns where rickets are prevalent. In the summer the amount of phosphate in the blood is higher than at any other season and fresh cases of rickets are rare. The amount of phosphate falls off in the autumn and winter and the number of cases of rickets increases.

MEETINGS OF OTHER SOCIETIES

THE OIL AND COLOUR CHEMISTS' ASSOCIATION

At a meeting held at Birkbeck College, London, on February 8, Mr. A. de Waele delivered a paper on "Viscometry and Plastometry."

In introducing the subject of the measurement of the factors governing the consistency of plastic bodies the author dealt with the elementary conceptions of viscous flow in liquids, including the mathematics of Poiseuille's law and the corrections to it. A form of plastometer adapted to the exigencies of routine work in technical laboratories for the study of either viscous liquids or plastic solids was next described and illustrated with lantern slides. In referring to the work of Bingham and his collaborators on the subject of the measurement of plasticity, the author pointed out that Bingham's fundamental equation purporting to illustrate the law of plastic flow, viz. :—

$$\frac{\pi R^3(F-f)}{4V} = \frac{\pi R^4(P-p)}{8Vl} = \eta$$

was *a priori* wrong since it implied a linear relationship between P and V at all shearing stresses above $P=p$, an assumption that could not be realised. Bingham's interpretation of the law of plastic flow had been examined by critical experiments and found to be invalid, no linear relationship having been found in any part of the line. The erroneous conclusions of Bingham and his co-workers, were due to the restriction of their investigations to materials possessing low degrees of plasticity in the first place, and secondly to the confinement of their observations to relatively low rates of shear. As a result, true curvature of the pressure-volume relationship had been mistaken for slippage, a phenomenon which Bingham, furthermore, in his mathematical treatment had incorrectly visualised. A slide illustrating the phenomenon of slippage showed that this takes place *inwards* from the capillary walls, and not outwards from the centre as Bingham had assumed.

In concluding, it was shown that beyond a small shearing stress in which some slippage might occur, the mechanism of plastic flow was continuous up to the point at which possible influences of turbulent flow or kinetic energy corrections might enter, the plastic flow equation being representable by the relationship :—

$$K\frac{P}{Q^{\phi}} = \xi$$

where P corresponded to shearing pressure, Q the volume exuded in unit time, K the capillary constant as deduced from Poiseuille's law, the exponent ϕ differing from that obtaining in viscous flow in being fractional and *less* than unity, and ξ being constant for the material sheared and possibly identical with viscosity. The confirmation of this identity was to be the subject of a subsequent communication. The value $(1-\phi)$ appeared thus in direct numerical proportion to the degree of plasticity.

THE FARADAY SOCIETY

The following papers were submitted to the Faraday Society at the meeting held in Burlington House on February 19 :—

Prof. A. W. Porter and Mr. J. J. Hedges, B.Sc., in Part II. of their paper, "The Law of Distribution of Particles in Colloidal Suspension with Special Reference to Perrin's Investigation," gave some results obtained by Constantin in his work on this subject, and then described their work on the suspension of paraffin in water, which has special interest since the particles are specifically lighter than the medium. It was found that the change in concentration occurred, as expected, at the bottom of the vessel and that there was an increase in concentration with height, reckoned from the bottom of the containing vessel. By plotting the numerical concentration against the relative depth, the following equation connecting these quantities was derived :—

$$\log_e \frac{n}{1-bn} + \frac{1}{1-bn} = Ky + A,$$

the constants being $b = 9{\cdot}7 \times 10^7$; $A = 83{\cdot}23$; and $K = -235$.

Three papers were contributed by Dr. D. B. Macleod, the first being entitled "The Relation between Surface Tension and Density. Dr. Macleod gave the following empirical relation connecting γ the surface tension at any temperature and the densities of liquid and vapour P_e and P_v at this temperature, C being a constant depending on the liquid :—

$$\frac{\gamma}{(P_e-P_v)^4} = C$$

and then proceeded to calculate by this formula the surface tension of such substances as ethyl acetate, ethyl ether, etc. The tables given in the paper show a close agreement between the calculated and observed values for temperatures taken between the melting point and the critical temperature of the substance. Agreement, however, in the case of associated substances is less satisfactory. The author pointed out that from this formula the surface tension should increase proportionally to the fourth power of the density, although no experimental data were available concerning the effect of pressure on the surface tension of a liquid. The next paper by this author was entitled "A Relation between the Viscosity of a Liquid and its Coefficient of Expansion," in which it was assumed that (*a*) the viscosity is dependent on the molecule itself, and in the case of normal unassociated liquids, independent of the temperature, (*b*) the viscosity is dependent upon the free space within the liquid. Assuming x_0 the free space in unit vol. at 0° C., and $\alpha\beta\gamma$ the coefficients of expansion, and that the volumes of the molecules remain constant over the temperature range under consideration, the value of the viscosity of the liquid at temperature t relatively to its value at 0° C. is given by $\frac{\eta_0}{\eta_t} = \frac{(x_0+\alpha t+\beta t^2+\gamma t^3)^A}{x_0}$ where A is a number which varies from 1 to about 3·4 depending upon the liquid. This formula has been applied to a number of liquids, and it is found that in every case the calculated result of the viscosity agrees very closely with the value found experimentally. The author also applies the same expression to the values for the viscosity of carbon dioxide and provides a table giving the constants (A) for a considerable number of liquids. Liquids having a value for A much greater than unity are known to belong to a class of substances whose molecules are associated at ordinary temperatures, and it is assumed that such an associated molecule encloses within the system a certain amount of free space, and, consequently, on cooling the viscosity increases more rapidly than with normal substances. This theory would lead one to expect a rise in viscosity with rise in pressure which agrees with the experimental results available. The third paper, "On the Viscosity of Liquid Mixtures showing Maxima," is really a development of the theory advanced in the previous paper. If two liquids, one mobile or limpid, *i.e.*, having a large amount of free space, and the other viscous, *i.e.*, having a small amount of free space, are mixed, the author considers that it is highly probable that the mobile liquid will share some of its free space with the molecules of the viscous liquid, thus leaving less free space for its own molecules, and so contributing a greater viscosity to the mixture than is proportional to its volume, since its free space has suffered a partial contraction, whilst the viscous portion would contribute less because of an equivalent expansion. This is expressed mathematically by

$$\eta=\eta_1 v_1\left(\frac{x_1}{x_1-\Delta x}\right)^{A_1}+\eta_2 v_2\left(\frac{x_2}{x_2-\Delta x}\right)^{A_2}$$

where η, η_1, η_2 are viscosities of mixture, mobile and viscous liquids, respectively; x_1, x_2 the free spaces in mobile and viscous liquid respectively; A_1, A_2 the constants for the pure substances. This formula is then applied to determine the viscosity of mixtures of such substances as pyridine and water, in various proportions, and tables and curves are given showing how the calculated value of η varies from that obtained by other workers.

In a paper on "The Crystal Growth in Cadmium," Mr. M. Cook, M.Sc., gives the results of experiments undertaken to determine whether recrystallisation or crystal growth can take place in metals not previously subjected to plastic deformation. The paper describes methods by which several unworked specimens of the same shape, size, etc., were prepared and etched so that they could be considered structurally alike, and the heat treatment to which each specimen was subjected. The results obtained indicate that in annealing considerable crystal growth takes place in the unworked specimens, but that no allotropic change is produced in the metal when heated to 100° C. The essential difference between worked and unworked specimens is that in the former new centres of recrystallisation are formed which are absent in the latter.

Mr. Jeffery, who has given in previous papers the reactions in electrolysis with anodes of silver, copper and lead, gave a paper on the results when using an aluminium anode, the anolyte being (1) solutions of sodium nitrate and (2) solutions of potassium oxalate. In the second case the experiments were designed to investigate a case in which an aluminium anode might form complex anions during electrolysis. The conclusions drawn were that, with solutions of sodium nitrite, the probability is that nitrogen peroxide ions react with the aluminium anode to give aluminium nitrite, which is hydrolysed rapidly to hydrated aluminium oxide and nitrous acid, the latter giving rise to nitric acid and nitric oxide. No evidence is given by these experiments of the formation of a complex ion of aluminium with solutions of sodium nitrite, but with potassium oxalate the product of reaction at the anode is a complex ion derived from aluminium.

A paper on "Electric Potential of Antimony Lead Alloys" was read by Mr. S. D. Muzaffar, who described how these measurements are made by a quadrant electrometer against a calomel electrode in N KOH, N $Pb(NO_3)_2$, and tartar emetic with tartaric acid solutions. By this means the possibility of electrolysis by the flow of current through the cell is avoided. The results, which are in agreement with those of Charpy and other workers, prove that no chemical compound is formed between the metals, that no solid solution is formed and that up to 98 per cent. of antimony the potential is identical with that of lead.

THE CHEMICAL SOCIETY

The following papers were selected for reading at the meeting held on February 15:—(1) "Spinacene: its oxidation and decomposition": A. Chaston Chapman. (2) "Investigations on the dependence of rotary power on chemical constitution. Part XIX. The rotary and refractive dispersion of d-γ-nonyl nitrite": R. H. Pickard and H. Hunter. (3) "Investigations on the dependence of rotary power on chemical constitution. Part XX. The rotary dispersive powers of oxygen compounds containing the secondary octyl radicle": H. Hunter. (4) "Studies on hypophosphorus acid. Part V. Its reaction with silver nitrate": A. D. Mitchell. (5) "The form of the vapour pressure curve at high temperatures. Part II. The curve for sodium cyanide": C. K. Ingold. (6) "The properties of ammonium nitrate. Part V. The reciprocal salt-pair ammonium nitrate and potassium chloride": E. P. Perman and H. L. Saunders. (7) "The morphine group. Parts I. and II.": J. M. Gulland and R. Robinson. (8) "A synthesis of pyrylium salts of anthocyanidin type. Part II.": D. D. Pratt and R. Robinson.

Owing to the number of papers on the list the authors merely summarised their communications, and none of the papers gave rise to any discussion. The meeting was presided over by Prof. Lowry and later by Prof. J. F. Thorpe. The following names were given as proposed for election as honorary Fellows: Bohnslow Brauner, Ernst Cohen, Gilbert Newton Lewis, Charles Moureu, Amé Pictet, and Theodor Svedberg. Prof. Pickard dealt with both papers on the investigation on the dependence of rotary power on chemical constitution and Prof. Robinson briefly summarised the last three papers on the list.

Mr. Chaston Chapman's paper on "Spinacene" amended, and added to, work which he had published in 1918. This substance, derived from shark-liver oil, he now considers to be a hydrocarbon, $C_{29}H_{48}$, with six ethenoid linkings; experimental data were adduced in support of the formula. On hydrogenation a colourless liquid, completely devoid of odour, was obtained, evidently the saturated hydrocarbon $C_{29}H_{60}$, for which the author proposes the name *spinacane* to indicate its relationship with *spinacene*. A dodecabromide, $C_{29}H_{48}Br_{12}$, was obtained, and treatment with hydrogen peroxide, the substance being resistant to ordinary oxidation, yielded a product $C_{27}H_{48}O_8$ and also a further one with acidic properties $C_{25}H_{44}O_7$. The decomposition of spinacene by heat alone produced an olefine hydrocarbon heparene, $C_{10}H_{18}$, whereas distillation with sodium under reduced pressure yielded as main product cyclo-dihydroterpene.

Prof. Pickard dealt with relationships between optical activity, refractive index, dispersion and absorption spectra. Coloured liquids were investigated, the effect of which appeared in a measurable part of the spectrum. The suggestion was made that geometrical isomerides might perhaps account for complex dispersion.

The case for tautomerism of hypophosphorous acid was stated by Dr. Mitchell, who suggested that the change from an inactive to an active form which affected reduction took place as follows:—

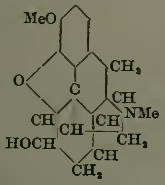
$$\begin{matrix}H\\H\end{matrix}\!\!>P\!<\!\!\begin{matrix}OH\\O\end{matrix}\ \rightleftarrows\ \left(\begin{matrix}H\cdot\\H.\end{matrix}\right)H_3PO_2 \rightarrow H_3PO_3.$$

inactive active

The active form is given as an empirical formula without assigning to it any particular constitution. The change is catalysed by hydrogen ions in both directions.

Dr. Ingold pointed out the four unwarranted assumptions made in calculating thermodynamically the connexion between latent heat of vaporisation and vapour pressure. Using the Nernst equation he applied an extrapolation test in the case of sodium cyanide. Dr. Perman drew diagrams of ammonium nitrate potassium chloride mixtures.

Prof. Robinson discussed formulæ for morphine. He suggested and gave evidence for a bridge formula:—



During the meeting Dr. A. Scott announced that he had received a letter from Messrs. Coster and Hevesy acknowledging the samples he had sent. Prof. Bohr had continued the examination and had found lines corresponding to no known element. The assumption is, therefore, that Dr. Scott's element is not hafnium. Dr. Scott stated that he was continuing work with the material he had at his disposal. He pointed out that the original sand from which he had isolated his oxide contained 25 per cent. titanium, whereas the sand which had been described as occupying a belt 70 miles in extent contained only 10 per cent. titanium. Hence the question of the correct kind of sand might be all important.

INSTITUTION OF PETROLEUM TECHNOLOGISTS

At the meeting held on February 13, Prof. J. S. S. Brame in the chair, Mr. G. W. E. Gibson presented a paper entitled "Some Practical Notes on Oil Pumping."

The author discussed various types of pumps and the methods by which they are driven, drawing attention to the Twells patent valve motion, which aims at the prevention of short stroking. Emphasis was laid on the necessity for suction mains of large diameter and for fitting large suction and delivery valves to pumps that were intended to handle very viscous liquids. The practice of listing the capacities of oil pumps in gallons of water was justified on the ground that, since the viscosity of oils is such a variable quantity, this method gave a reliable figure, from which the practical oil man could determine the pump's performance when handling a particular oil. A view of a pump, used for transporting oil at 400° C., was shown. In this pump the moving parts were protected from the hot oil by a column of cold liquid. During the discussion, in which Messrs. Anfilogoff, Barringer, Challenger, Evans, Professor Hinchley and Dr. Ormandy took part, the opinion was expressed that piston pumps were quite as suitable as plunger pumps for high pressure work. Some speakers objected to belt-driven pumps on the ground that sparks caused by electrical discharges from the belts were dangerous, especially if the pump was used with low flash-point oils. Similar arguments were advanced against the use of high-speed centrifugal pumps. The absorption of oxygen by oil was advanced as one of the contributory causes to the necessity for frequent renewal of air in the air vessels of oil pumps. Other views were expressed that greater attention should be given to the design of suction orifices, and that pumps should be designed with a view to efficiency rather than cheapness.

SAFEGUARDING OF INDUSTRIES ACT

The Board of Trade has received complaints that Rochelle salts and formaldehyde have been improperly included in the lists of articles dutiable under Part I. of the Act. Those interested should communicate at once with the Board.

CORRESPONDENCE

PROFESSOR ARMSTRONG AND THE SMOKE ABATEMENT COMMITTEE

Sir,—I do not wish to prolong a discussion on the above subject, but I would like to offer a word in reply to Professor Bone, because I think that neither he nor Professor Armstrong quite grasp the main object of the Committee. It was not to advise about the best method of stoking a boiler or of firing any other form of furnace or of economising fuel, or even about the kind of fuel to use, but to suggest legislation which should afford the strongest possible inducement to the community to reduce the amount of smoke discharged into the air. When the Committee was told by men intimately acquainted with boiler practice that a boiler chimney need not emit smoke, it does not require the technical knowledge of a Professor Bone or Armstrong to devise efficient regulations to stop smoke from boiler chimneys. The function of the technical expert is made quite clear in Professor Bone's letter, in which he suggests a sort of advisory committee such as was established long ago abroad. Let the manufacturer who gets into difficulties with the authorities go to this committee for advice.

Any common-sense person with a judicial mind and a *trustworthy knowledge of the facts* can draft a good smoke abatement Bill. The great difficulty in a matter of this sort is in obtaining trustworthy information, and for that reason some technical member on such a committee is, of course, desirable. So far I quite agree with the critics.—I am, Sir, etc.,

J. B. Cohen

The University, Leeds.
February 16, 1923.

SMOKE ABATEMENT

Sir,—I hope this correspondence of our gifted experts may not end in smoke! It seems to me as an outsider—seeing a good deal of the smoke—that industry is likely to take much more care of its fuel in the near future owing to higher prices, and there will be sufficient driving force towards reform.

And our humble homes are quite commonly reduced to one smoky fire instead of the three or four of past times. We have been driven to save labour and smoke.

The only practical way of eliminating domestic smoke—for one fire we must have—is for gas works to supply us with smokeless solid fuel.

Gas works alone have the right to distribute gas, the valuable by-product of smokeless fuel. A special company proposing to make smokeless fuel cannot market its gas to any advantage; it may indeed, I have seen it so done, have to dispose of gas to be burnt under steam boilers!

Gas works having a monopoly are our only hope, and so far they have declined to act; they are satisfied, perhaps justly, with the progress of their efforts to eliminate smoke by greater use of gas and do not wish to enter what is to them an untried field.

But we consumers can help them. I am sure that if a gas company or municipality would erect a special plant to produce a free-burning smokeless fuel with a guaranteed low ash content, it would be perfectly easy to secure a guaranteed consumption of the fuel at the market price of coal, by a few thousand well-wishers of the smokeless movement. Many of us would gladly put up with a not quite perfect product in the experimental stage if we felt that clearer skies were in sight!

S. F. Dufton

Wallington, Surrey.
February 19, 1923.

PERSONALIA

Mr. G. S. Pawle has been appointed chairman of Walkers, Parker & Co., Ltd., in place of Mr. David Thomson, who has resigned, but retains his seat on the board.

Mr. D. C. Henry, M.A., has been appointed Lecturer in Colloid Physics in the University of Manchester, and will take charge of the newly-established colloids research laboratory.

The Greenwell Medal of the North of England Institution of Mining and Mechanical Engineers was presented in Newcastle on February 10 to Professor R. V. Wheeler, D.Sc., of Sheffield University, for researches into the chemical and physical properties of coal.

Mr. A. E. Levey, who has for the past five years been the chief technologist to the margarine and lard compound departments of the British Oil and Cake Mills, Ltd., Hull, has resigned his appointment and is leaving for the United States of America early in April.

Lieut.-Col. G. R. Lane-Fox, H.M. Secretary for Mines, has appointed Sir R. A. S. Redmayne chairman, and Messrs. J. Kane, A. M. Lamb, J. Till, and the Rt. Hon. T. Richards members of a committee to prepare, under the direction of the Safety in Mines Research Board, a scheme for investigating methods of reducing the number of accidents from falls of ground in coal mines.

* * *

Mr. P. C. A. Stewart, the well-known petroleum geologist, has been drowned while bathing in Balandra Bay, Trinidad.

The death is announced of Mr. D. Y. Cassels, senior partner of the firm of Pott, Cassels and Williamson, engineers and founders, Motherwell, near Glasgow.

With much regret we announce the death of Mr. Arthur Carey, at one time chairman of the Liverpool Section of the Society of Chemical Industry. An account of Mr. Carey's career was given in our last issue.

NEWS AND NOTES

BRITISH INDIA

The Coal Industry

A report on the production and consumption of coal in India in 1921 has been issued as a supplement to the *Indian Trade Journal* of January 25, 1923. The output of coal during 1921 amounted to 19,303,000 tons, an increase of 7·5 per cent. over the output in 1920, but about 3 per cent. less than the record production in 1919. By far the largest proportion of the output is produced in the Bengal, Bihar and Orissa coalfields, that of Jherria alone producing over 52 per cent. of the total. The average value of the coal at the pit's mouth per ton was 6 Rs. 12 A., compared with an average value in the United Kingdom for the five years ending 1920 of 15 Rs. 9 A. Altogether 205,879 persons were employed, the average output per person employed being 94 tons, compared with 743 in the United States, 184 in the United Kingdom, and 155 in Germany. This small output is due to the fluctuating supply of labour, but production will probably increase within the next few years as coal-cutting by machinery is extending.

Exports of coal during 1921 totalled 275,571 tons, and imports 1,090,749 tons. Of the coal consumed 30·8 per cent. is utilised on the railways, 7·1 per cent. is utilised in iron, steel and brass foundries, and 2·2 per cent. in brick and tile factories, potteries and cement works. Owing to the fact that the coal now being won in India is comparatively near the surface it costs less at the pit's mouth than coal in any other country, and with the discovery of new and valuable fields, coal-mining in India offers prospects of important development.

JAPAN.

Paper Combine in Japan

Japanese manufacturers of wood pulp have been forced to form a combine with a capital of 3 million yen under the name of Kyoto Pulp Kaisha to meet foreign competition both at home and abroad. The difficult situation caused by strong Canadian competition is to be met by the reduction of the total annual productive capacity from 120,000 to 100,000 tons. —(*U.S. Com. Rep., Jan.* 1, 1923.)

GENERAL

Ramsay Memorial Fellowship Trust

This Trust, which has just issued a report and accounts for the year ending August 31, 1922, was constituted for the purpose of administering the Ramsay Fellowships for chemical science. The report is a very striking document, disclosing, as it does, the wonderfully international character of the Ramsay Memorial. Records are given of three general Fellowships, all of which have been awarded and are held by students actively engaged upon research, one at Oxford and two at University College, London. The Fellowships associated especially with Glasgow, Japan, Canada, Sweden, Norway, Switzerland, Denmark and Holland have all been awarded, whilst those of Greece, Italy, Spain and France have not yet been filled. A considerable number of the Fellows will work under Professor Donnan in London, but a fair number of Fellows go to other chemical centres in the country. The annual value of the Fellowship is usually about £300, and in one or two cases considerably higher. Japan gives £460. It is certainly a matter of great gratification to see this change of attitude in chemistry, provision now being made for the access of foreign students to higher chemical studies in this country. It is something like a reversal of the conditions which prevailed a generation ago. Certainly no chemist could wish for a nobler memorial to Ramsay than that now associated with his name.

The New Botanical Laboratory of the Imperial College.

On February 16 the Duke of Devonshire opened the new Botanical Laboratory of the Imperial College of Science and Technology in the presence of a distinguished gathering. The new laboratory, which is devoted to plant technology, forms part of a scheme of development of the Imperial College, which aims at providing men qualified to investigate and advise on problems relating to plant growth, such as parasitic diseases, manuring and plant breeding, as well as the manufacture of plant products. Space and equipment is provided in the laboratory for the study of all these problems and an interesting series of exhibits, ranging from diseases of the rubber tree, methods of preserving latex, and apparatus for investigating the vital functions of plants, to specimens illustrating the manufacture of tiles from castor-seed residues, indicated the wide scope and industrial bearing of the new department. In declaring the laboratory open the Duke of Devonshire instanced the enormous importance of the application of science to the many problems inherent to agricultural development by stating that in tropical Africa alone the British Dependencies covered an area of a million square miles and contained some thirty million inhabitants who were almost solely dependent on agriculture for their prosperity.

New British Chemical Standard: Basic Slag "A."

The organisers of the British Chemical Standards' Movement announce the issue of a basic-slag standard. The special uses of the slag are :—(1) Primarily as an analytical standard for total phosphoric acid and phosphates ; (2) in addition, as a standard mainly for basic-steel makers, but also for acid-steel makers, iron and steel founders and others, to enable them to check their methods for silica, iron, lime and magnesia, etc., in slag.

The analysis is as follows, per cent. :—Phosphoric anhydride (P_2O_5), 12·93 ; equal to phosphates [$Ca_3(PO_4)_2$], 28·24 ; iron, 8·97 ; silica, 16·15 ; lime and magnesia to follow.

During the standardisation of this slag the need for such a standard has been made abundantly evident, for it has been found that even in the determination of such elements as iron, silica, lime and magnesium, which, it may be thought, presents little or no difficulty, improvements in methods have been essential in order to get agreement between experienced chemists. The standard has been tested by a selection of sixteen prominent chemists representing :—Independent analysts : (1) metallurgical, (2) agricultural ; U.S. Bureau of Standards ; English and French iron and steel works chemists (manufacturers) ; English basic-slag grinders and merchants.

The standard sample may be obtained in 100 or 50 gramme bottles at a price just sufficient to cover the cost, either direct from Organising Headquarters, 3, Wilson Street, Middlesbrough, or through any of the leading laboratory furnishers. A certificate giving the names of the analysts co-operating, the types of methods used, and a detailed list of the results will be supplied with each bottle. A special feature of this certificate is the very full notes on the methods used by the different chemists (3 quarto pages in small type). It is hoped that chemists will take full advantage of this standard which has been prepared with the object of promoting unification of analysis.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for February* 15)

TARIFF CUSTOMS EXCISE

Antigua.—Revisions in the export duties affect sugar, syrup, molasses, and cotton.

Australia.—" Dumping exchange " duties have been applied to goods from Czechoslovakia. The prohibition on the importation of calcium carbide has been removed. The application of import duties on citric acid, gunpowder, etc., and certain wares of iron and steel has been deferred.

Austria.—Export licences are required for crude potash salts, supephosphates, manures and fertilisers, and gas-purifying material.

Germany.—The text of the customs regulations of the territory occupied by France and Belgium is given in the issue for February 15.

Italy-Switzerland.—The text of the commercial treaty signed on January 27 is given in the issue for February 15.

Morocco (French).—A decree has been issued regulating the importation and sale of opium, morphine, heroin, cocaine and hashish.

Norway.—All the rates of the customs tariff have been increased by 20 per cent., except those affecting sugar and goods on which the duties are fixed by Treaty.

Rumania.—The export of hides of all kinds is prohibited.

San Salvador.—The import duties on a wide range of pharmaceutical specialities have been reduced from 1 dollar to 40 centavos (gold) per kg.

Switzerland.—The special tax on imported coal has been reduced from 40 to 25 centimes per 100 kg.

Tunis.—The import duties on coal-tar dyes have been further modified.

Uganda.—Regulations controlling the purchase, sale, production, etc. of cotton have been issued.

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia ..	Tiles	198
,, ..	Ammonium chloride, Leclanché cells and jars (tenders for) ..	10542/E.D./1/C.C. and 2/M.C.
British Guiana	Portland cement, galvanised sheets ..	201
Canada ..	High-speed steel ..	202
,, ..	Drugs	204
,, ..	Wire	10459/E.D./E.C.2.
Egypt ..	Soft soap (tender for)	*
Haiti	Cement	7476/F.L./M.C./2.
Japan ..	Glass, glassware ..	225/14/F.G./M.C./A.
South Africa..	Oxygen gas (tender for)	10549/E.D./C.C.
Spain	Iron ore, coal ..	216
,, ...	Fertilisers, agricultural chemicals	217
Switzerland ..	Paper	218
United States	Shellac..	18088/F.W./C.C.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Ammonium Sulphate

Sir R. Sanders, replying to Sir B. Sheffield, said that the present price of neutral ammonium sulphate containing 25·37 per cent. of ammonia was £16 18s. per ton. As the increase of price compared with that in February, 1922, was only 1·5 per cent., no profiteering existed.—(Feb. 15.)

Dangerous Drugs and Poisons (Amendment) Bill

Mr. Bridgeman presented the above Bill to amend the Dangerous Drugs Act, 1920, and Section 17 of the Pharmacy Act, 1868, and to prescribe a method of calculating percentages in liquid preparations for the purpose of the Poisons and Pharmacy Act, 1908, and the Dangerous Drugs Act, 1920.—(Feb. 15.)

Chemical Trade Regulations

In reply to Mr. Wignall, Mr. Bridgeman said that the Draft Welfare Regulations for the chemical trade were made in July last, and many of them came into force on October 1. Strong objection, however, was taken to the enforcement of certain of the regulations which would have involved structural alterations, and it was agreed that these requirements should not be enforced until a date to be fixed by the Home Secretary.—(Feb. 15.)

Merchandise Marks Bill

Sir W. Joynson-Hicks informed Sir J. Hood that he was considering questions relating to this Bill and could not say when it would be ready.—(Feb. 15.)

REVIEWS

The Official Directory of Members of the Association of British Chemical Manufacturers, with Classified List of their Manufactures. *Pp.* 319. *Published by the Association*, 166, *Piccadilly, London. Price* 10*s*. 6*d*.

This volume, published by the Association of British Chemical Manufacturers, constitutes a valuable guide for the purchase of chemical products of all kinds. Printed in English and in five other languages, it will be found of great value to intending purchasers, as the list of chemical products covers a very wide range, and in addition a supplementary list of proprietary and trade names, comprising the scientific name of the products and the name of the manufacturer, is also given. An interesting feature is that in ordering any of the products contained in the list, purchasers can be certain that the goods they order are actually produced in this country, as all members of the Association are *bonâ-fide* manufacturers. The enterprise of the Association in issuing this handy and conveniently arranged volume is to be commended, and it is to be hoped that it will be used extensively by all those who purchase or use chemicals.

Modern Gasworks Chemistry. *By* Dr. G. Weyman. *Pp. ix*+184. *London: Benn Brothers, Ltd.*, 1922. *Price* 25*s. net.*

Dr. Weyman is to be congratulated on his excellent book, which so admirably fulfils its object, viz., to describe the methods of controlling plants and processes in everyday use in the gas industry. The book is divided into chapters dealing with Coal—Carbonisation—Coke; Maintenance of Heats; Refractory and Insulating Materials, Tar; Ammonia; Oxide Purification; Town Gas; Water Gas; Steam Raising and Water Supply; Lubricants. Each chapter consists of a brief discussion of the subject to which it is devoted, methods of control and analysis being given, followed by a list of references to books or original papers bearing on the text. The book practically covers the whole field of chemical methods, without being overburdened with detail.

The value of the book lies in the fact that it is not merely a compilation of tests and methods culled at second hand, but has been written after much careful thought, and sifting of methods by trial from the author's own personal experience. As instances of the scope and utility of the book to the gas engineer and chemist engaged in the industry, Chapter III deals with the chemical control of the carbonisation process; the choice and blending of coals; and the conditions conducing to the efficient working of the retorts; time and yield factors; gas sampling and analysis. Chapter V deals with the maintenance of heats; causes of fluctuation; the various methods of pyrometric control, and analysis of producer gas. Chapter VII, on Tar, describes the recovery of tar from crude gas; the importance of temperature control in the cooling and condensing system; the methods of analysis of tar and its primary distillation products. Chapter VIII covers the production of ammonia from the retort house until finally sent away as sulphate. The book is well got up and well illustrated. It contains a list of useful tables, as well as a subject index and name index.

One important subject has been omitted altogether, viz., the removal and recovery of cyanide compounds, a subject vastly more important to the manufacturer of gas than the question of lubrication.

Dr. Weyman has produced an exceedingly useful and practical book, which fills a long-felt need, and one feels sure that the book will find a ready welcome from all interested in gas manufacture.

W. A. Walmsley

(1) Calculations of Quantitative Chemical Analysis. *By* L. F. Hamilton *and* S. G. Simpson. *International Chemical Series. Pp.* x+196. *New York and London. McGraw-Hill Book Co.*, 1922. *Price* 10*s*.

(2) A Systematic Qualitative Chemical Analysis. *By* Prof. G. W. Sears, Ph.D. *Pp.* vi+119. *New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.*, 1922. *Price* 8*s*. 6*d*.

(1) This volume keeps strictly to its title subject—the calculations of quantitative analysis, avoiding the calculations of pure and physical chemistry, and hence meets a decided want. The author rightly states that the knowledge of the chemical principles of analysis and the acquirement of manipulative skill are of little practical value unless they are accompanied by the ability to compute and interpret results from analytical data quickly and correctly. Certainly the student who works systematically through this volume cannot fail to achieve this desired ability. The general arrangement of the volume is to take typical chemical problems arising out of gravimetric and volumetric analysis, subdividing them into problems relating to atomic-weight determinations, electrolysis, oxidation and reduction processes, gas analysis, etc., and after a very brief description of the chemical reactions involved, to treat the problems on simple arithmetical or algebraical lines, first giving a fully worked-out example and then numerous cognate problems with answers attached. The examples given are extremely apt and well chosen and of a most practical nature. It is particularly interesting to note that the authors introduce at every possible opportunity moisture, impurity, burette and volumetric factor corrections, such as are invariably found in practical analysis, thereby impressing their importance and reality on the student. The volume can be strongly recommended as a companion volume to any text book of quantitative analysis. The type is excellent and remarkably free from printers' errors. Some useful tables are appended, but it would have been advisable to have also included a comprehensive table of factors for volumetric and gravimetric analysis, particularly as some care is taken in the text to explain how they are obtained and used.

Nearly three hundred questions without answers are appended. The reviewer cannot resist the temptation to quote one as indicative of the ingenuity displayed in their selection:—"A sample of soda ash is given to a student for analysis. He uses a 0·9000 gram sample and titrates with 0·3/N HCl, passing the end point and running back with exactly 8 c.c. of 0·3/N NaOH. His NaOH burette is accurately graduated, but the bore of the other burette, although uniform throughout its entire length, is not of correct size to agree with the graduations. Not knowing this, the student calculates the analysis and reports 64·50 per cent. Na_2CO_3 If he had used the accurate burette for the HCl and the other burette for NaOH, he would have reported 66·33 per cent. What was the true per cent. Na_2CO_3 in the sample?" As quite a number of similar questions are given it is obviously advisable for a student who knows his future examiner to be in possession of this volume to arm himself similarly.

(2) It is difficult to see what justification there is for a book such as the one under review, the subject matter of which is largely to be found in any one of the innumerable existing text books on qualitative analysis.

For the detection of metallic radicles the usual group precipitation methods are given, interposed with a brief discussion of the reactions involved and precautions to be taken, but the text is of that irritating description necessitating the constant turning of pages to follow out a given procedure. The following extract gives a good idea of the author's style:—"Acidify the filtrate with HNO_3 noting if a gas is evolved (see discussion 60), and treat by (110), treat the residue by (101)." When the number happens to be wrongly quoted as on p. 43, line 19, the reader finds himself instructed to carry out the tests for the members of the copper group on the solution obtained after addition of stannous chloride to the mercuric sulphide precipitate after dissolving in aqua regia. A judicious use of schematic diagrams would probably have resulted in cutting down the text by half with a more than corresponding increase in lucidity.

For the identification of acid radicles a new scheme is given following the method of procedure generally adopted for metallic radicles *i.e.*, a single sample is taken and the acid radicles separated and detected by a series of group reactions. The scheme, however, is only applicable to a very limited number of inorganic and organic acids and no provision is made for the identification of acids, *e.g.*, formates, chlorates, iodates, etc., which do not fit into the scheme.

For the elementary student working with carefully selected simple mixtures the volume might be of some value, but a mixture of quite moderate complexity would speedily force him to refer to a more comprehensive, although not necessarily larger volume. The absence of alternative and confirmatory tests for acids and bases other than those given in the group reactions as well as the absence of any index greatly reduces what value the book might have. The volume is well bound and printed, but contains an inexcusably large number of typographical errors, particularly in chemical formulæ.

T. Callan

Starch and Starch Products. By H. A. Aunden, M.Sc., D.Sc. *Pitman's Common Commodities and Industries Series. Pp.* xiii—121. *London : Sir Isaac Pitman and Sons, Ltd.*, 1922. *Price* 3*s*.

Events of recent years have served to remind us rather forcibly of the importance of starch-producing plants and of their scientifically-controlled cultivation. Apart from the food requirements of the human race there are numerous industrial demands upon starch and its products, and lastly, its potentialities as a source of power alcohol render its increased production in the future a matter of great importance.

In this little book there is a brief but comprehensive sketch of the world's chief natural resources in this respect. There is a chapter devoted to each of the more important sources of starch, dealing with the methods of cultivation, and the primitive and modern processes of preparation and purification of the final product.

Like the rest of the series, this book deals mainly with the industrial and technical aspects of the subject. It contains comparatively little pure chemistry. One chapter deals with general properties, another with the production of glucose, dextrin, etc. ; whilst another is devoted to the fermentation products. Although the book is not necessarily written for chemists, there are one or two mentionable instances of lack of precision in dealing with chemical matters. Perhaps the most pronounced is where the author, discussing the products of acid hydrolysis of starch, says : "This sugar has been proved to be identical with that found in sweet fruits and honey, and for this reason has received the name of grape sugar, fruit sugar, or glucose." Fruit sugar is a name for fructose or lævulose, which occurs together with glucose or grape sugar in many sweet fruits, and in honey.

A number of illustrations (mostly technical) and a large quantity of interesting information of a general and diverse character, are given, but, as already inferred, the scope of the book is industrial rather than chemical.

R. H. Hopkins

REPORT

Report on the Finance, Industry and Trade of Peru, Dated September, 1922. *By* A. J. Hill, *Acting H.M. Consul, Callao. Pp.* 23. *Department of Overseas Trade. H.M. Stationery Office.* 1923. *Price* 9*d*.

There are three distinct natural divisions in Peru. The Pacific coastal region, containing most of the cities and of the white population, produces principally sugar, cotton, petroleum, wool, hides and skins. The mountain region, though exceedingly rich in minerals, cannot be thoroughly developed owing to the lack of railways. The tropical lowlands of the Amazon region have hitherto depended for their prosperity on the collection of wild rubber, though the forests would provide an almost unlimited quantity of pulp wood and timber.

The sugar production for 1921 is estimated at under 300,000 tons, an improvement being anticipated for 1922. Although Peruvian rubber is available in enormous quantities, the cost of transport renders it unable to compete with that from the other markets. The most important copper-producing concerns are the Cerro de Pasco Copper Corporation and its subsidiary company, the Backus and Johnston Mining Co. The total output of copper in 1921 was 33,284 tons, the output in 1922 being estimated at about 35,000 tons. Development of the petroleum industry in Peru has been delayed, but in January, 1922, a new law came into force governing the granting of "exploration concessions," and 1923 is likely to see extensive prospecting. In 1921 the output of petroleum was 488,669 tons against 373,280 tons in 1920. The Backus and Johnston Mining Co., at Casapalca, and the Anglo-French Ticapampa Mining Co., at Ticapampa, produced 9,855,000 oz. troy of silver in 1921. Coal was produced in 1921 to the extent of 357,315 tons, but was insufficient for the needs of the producers, the Copper Corporation (Cerro de Pasco). Gold was mined in 1921 to the extent of 77,400 oz. troy. Only 1776 tons of vanadium grade ore (20 per cent. grade) was produced, owing to the closing of the Mina Ragra mine early in 1921. Exploration for mercury is being carried on at Huancavelica, so far without success. The chief industries carried on in the country include copper-smelting, sugar-refining, cotton-seed oil refining, soap-making and tanning. Trade depression has continued throughout the period covered by the report, but with little buying from abroad, and reduction of existing stocks, and with a favourable trade balance, a better time appears likely.

The latest complete trade figures are for 1920 (for 1919 see J., 1922, 162 R), when exports amounted to £p.35,304,155 (£p.1 = £1 at par), the United States taking 46·1 per cent. and the United Kingdom 35·9 per cent. The chief items were :—Sugar, £15,584,889 ; hides, £358,426 ; rubber, £200,738 ; cocaine, £35,932 ; alcohol, £33,868 ; metals, £4,978,699 ; salts (borates), £3166 ; petroleum, £1,430,953. Imports were valued at £18,358,223, of which the United States supplied 55·4 per cent. and the United Kingdom 14·7 per cent. In the analysis appear :—Colouring materials, £805,761 ; liquors, £584,418 ; medicinal products, £984,856. More recent figures show that in 1921 exports amounted to £15,700,616 and imports to £15,521,706 ; for the first half of 1922 the corresponding figures are £7,937,052 and £4,780,889. Competition of British goods, particularly with American, continues keen ; German and Japanese goods are also on the market.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

There is little or no change to record in the Chemical Market.

Acid Acetic, 40% tech. ..	£22 per ton. Firmness of position continues, with tendency for price to rise.
Acid Hydrochloric ..	4s. to 5s. carboy d/d.
Acid Nitric, 80° Tw. ..	£25 10s. per ton.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw., is 70s. f.o.r. makers' works with slight variations up and down due to local considerations
Acid Sulphuric, 94% arsenical	£6 10s. per ton.
Ammonia Alkali ..	£7 12s. 6d.-£8 per ton. Rather quieter tone.
Arsenic (Alkali) ..	£75 per ton. Shortage continues, but inquiry not quite so brisk.
Bisulphite of Lime ..	£7 per ton, packages extra and returnable.
Bleaching Powder ..	£10 10s. per ton. Not much change.
Calcium Chloride ..	£6 per ton d/d. Considerable quantities reported imported from the Continent.
Copper Sulphate ..	£26 10s. per ton f.o.b.
Potash Caustic, 88/90%	£29-£30 per ton. No change.
Potass. Bichromate ..	6¼d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s.-£5 10s. per ton. Considerable American inquiry, but not much business passing up to the present.
Soda Caustic, 76% ..	£20-£21 per ton. In slightly better request.
Soda Crystals	£5 10s. per ton carr. paid. No change.
Sod. Acetate, 97/98% ..	£23 10s. per ton. In fair demand. Price firm.
Sod. Bicarbonate ..	£10 10s. per ton. Still in fair demand.
Sod. Bisulphite Powder, 60/62%	£19-£20 10s. per ton f.o.b. or f.o.r. London.
Sod. Chlorate	Market very dull and prices not at all firm.
Sod. Nitrite	£30 per ton 100% basis d/d.
Sod. Sulphide, solid ..	£16 per ton carr. paid. Price unsteady and demand still very poor.
Sod. Sulphite, Pea Cryst.	£17-£17 10s., 1-cwt. wooden kegs included.

WOOD DISTILLATION PRODUCTS

There is a brisk inquiry for products generally, and prices remain firm or show a slight upward tendency.

Acetate of Lime—	
Brown	£9 per ton d/d.
Grey	£18 10s. per ton d/d.
Liquor	9d. per gall. 32° Tw. d/d.
Charcoal	£9 10s.-£10 per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw. 1s. 2d. ,, , 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 6d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	7s. ,, ,, 80% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£5 per ton d/d.
Brown Sugar of Lead ..	£38 per ton d/d.

TAR PRODUCTS

Acid Carbolic, Crude 60's	2s. 11d. to 3s. per gall. Good demand.
Acid Cresylic—97/99 ..	2s.-2s. 3d. per gall.
Pale 95%	1s. 10d.-2s. 2d. per gall.
Dark ..	1s. 8d.-2s. per gall.
Anthracene Paste, 40%	4d. per unit per cwt. No business, price nominal.
Anthracene Oil—	
Strained	9d.-11d. per gall. Fair inquiry.
Unstrained	8½d. per gall.
Benzole—	
Crude 65's	1s. 1½d.-1s. 2d. per gall.
Standard Motor ..	1s. 8d.-2s. per gall.
Pure	2s.-2s. 2d. per gall.
Toluole—90%	1s. 9d.-2s. per gall.
Pure	1s. 11d.-2s. 3d. per gall.
Xylol	2s. 9d.-3s. 3d. per gall.
Creosote—	
Cresylic, 20/24% ..	10½d.-1s. 1d. per gall. Fair inquiry.
Middle Oil	7¼d.-9¼d., according to district. Plenty of enquiries.
Heavy	
Standard Specification	
Naphtha—	
Crude	9d.-9½d. per gall.
Solvent, 90/160 ..	1s. 7d.-1s. 10d. per gall. Market dull
Solvent, 90/190 ..	1s. 7d. per gall. Little or no business doing.
Naphthalene, Crude—	
Drained Creosote Salts	£6-£9 10s. per ton Market short.
Whizzed or hot pressed	£10-£12 per ton. Fair enquiry.
Naphthalene—Crystals ..	£17 per ton.
Flaked ..	£15 per ton.
Pitch, medium soft ..	155s.-160s. f.a.s. Manchester. Many buyers.
Pyridine—90/140 ..	10s. 6d.-12s. 6d. per gall. Not much business doing.
Heavy ..	8s.-9s. per gall. Price nominal. No business.

INTERMEDIATES AND DYES

Business in Aniline Dyestuffs still remains good. A fair amount of business has passed, and there is every indication that there will be a still further increase in the volume of trade. Prices remain very firm.

Acetic Anhydride ..	1s. 5d. 100% basis.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic ..	2s. 7½d. lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic ..	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride, anhydrous	1s. per lb. d/d.
Aniline Oil and Salts ..	10d. per lb. naked at works.
Antimony Pentachloride	1s. 1d. per lb.

Benzidine Base ..	.. 6s. 6d. per lb. 100% basis.
Benzyl Chloride ..	.. 1s. 4½d. per lb. 100% basis.
Dinitrobenzene ..	.. 11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	.. £95 per ton.
Dinitrophenol ..	.. £140 per ton.
Dinitrotoluene—48/50 ..	8d.-9d. naked at works.
66/68 ..	1s. 2d.-1s. 3d. naked at works
Diphenylamine ..	.. 4s. per lb. d/d.
Dichloraniline ..	.. 2s. 2d. per lb. 100% basis.
Dichloraniline S Acid ..	2s. 4d. per lb. 100% basis.
Diethylaniline ..	.. 4s. 6d. per lb. d/d, packages extra.
Metanitraniline ..	.. 5s. 6d. per lb. d/d.
Meta Phenylene Diamine	5s. 6d. per lb. d/d.
Meta Toluylene Diamine	5s. per lb. d/d.
Monochlorbenzol	.. £70 per ton.
α-Naphthol ..	.. 2s. 9d. per lb.
β-Naphthol ..	.. 1s. 1d. per lb. d/d.
α-Naphthylamine	.. 1s. 6½d. per lb. d/d.
β-Naphthylamine	.. 4s. per lb. d/d.
p-Nitraniline ..	.. 2s. 8d. per lb. d/d.
Nitrobenzene ..	.. 7½d. per lb., drums extra.
Nitronaphthalene	.. 1s. per lb. d/d.
Naphthionate Soda	.. 2s. 8½d. lb. 100% basis d/d.
Orthonitrochlorbenzol ..	2s. per lb.
Paradichlorbenzol	.. £55 per ton.
Paranitrophenol	.. 1s. 9d. per lb. 100% basis.
Parachloraniline	.. 3s. per lb. 100% basis.
p-Nitro-*o*-amido-phenol ..	4s. 6d. per lb. 100% basis.
Para Phenylene Diamine	12s. per lb. 100% basis d/d.
Para Toluidine ..	.. 5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid Acetic, 80% B.P. ..	£45-£47 per ton. Good inquiry. Prices have upward tendency.
Acid Acetyl Salicylic	.. 3s. per lb. Market exceedingly firm owing to continued increase in cost of raw materials.
Acid Benzoic ..	.. 2s.-2s. 2d. per lb. Not much on offer for spot delivery.
Acid Boric, B.P.	.. £61 per ton Crystals, £65 per ton Powder, packages in 2-cwt. bags, carr. paid U.K. Market steady.
Acid Citric ..	.. 1s. 7d.-1s. 9d. per lb. Market quiet.
Acid Gallic ..	.. 3s. per lb.
Acid Pyrogallic, cryst. ..	5s. 6d. per lb.
Acid Salicylic ..	.. 1s. 7d. per lb. Market stiffening up owing to carbolic position.
Acid Tannic ..	.. 3s. 3d. per lb. Unchanged.
Acid Tartaric ..	.. 1s. 2½d., less 5% demand still good. In spite of the depreciated exchanges the Raw Material Market remains difficult and prices continue to advance. For this reason alone the price of the finished article is likely to rise still further in the near future.
Acetanilide ..	.. 1s. 6d. per lb. neglected.
Amidol	.. 9s. per lb.
Amidopyrin ..	.. 13s. per lb. weaker.
Ammon. Benzoate	.. Still 3s. lb. for good makes.
Ammon. Sulphocyanide	2s. 6d. lb. for recrystallised.
Barbitone ..	.. 12s. 6d. per lb.
Benzonaphthol ..	.. 5s. per lb.
Bismuth Salts ..	.. Prices per lb. for cwt. lots are as follows:—Carbonate 13s., Citrate 11s. 7d., Nitrate cryst. 6s. 11d., Oxide 14s. 5d., Salicylic 10s. 5d., Subchlor 12s. 8d., Subgallate 9s. 6d., Sub. nitrate 11s. Fairly good market.
Bromides ..	.. Still in plentiful supply. Market unsettled.
Chloral Hydrate	.. 4s. lb. weaker.
Formaldehyde 40%	.. £90-£92 10s. per ton.
Guaiacol Carbonate	.. 8s. 6d. per lb. for small quantities. 8s. per lb. would be accepted for 1-cwt. lots.
Hexamine ..	.. 4s. per lb. now asked for spot parcels.
Homatropine Hydrobromide	.. 30s. per oz.
Iron Ammon. Citrate ..	B.P. 2s. 5d. lb. } Fair demand. Green 3s. 1d. lb. }
Magnesium Carbonate—	
Light Commercial	.. £40 per ton.
Magnesium Oxide—	
Light Commercial	.. £89 per ton.
Heavy Commercial	.. £29 per ton.
Menthol ..	.. 37s. per lb. less 2½% for original cases. Small quantities 37s. 6d. nett.
Methyl Salicylate	.. 2s. 3d. per lb. Slightly higher
Methyl Sulphonal	.. 13s. per lb.
Mercurials ..	.. Weak market.
Paraldehyde ..	.. 1s. 6d. per lb.
Phenacetin ..	.. 5s. per lb. Unchanged owing to lack of demand.
Phenazone ..	.. 7s. per lb.
Phenolphthalein	.. 5s. per lb. weaker, but lower prices would be acceptable for definite orders.
Potass. Bitartrate 99/100% (Cream of Tartar)	97s. 6d.-100s. per cwt. for ton lots less 2½%. Market firm.
Potass. Iodide ..	.. 15s. 8d. per lb. for cwt. lots. Cases free. Demand still good.
Potass. Metabisulphite ..	8d. per lb.
Potass. Permanganate ..	8½d. per lb.
Quinine Sulphate	.. 2s. 3d.-2s. 4d. per oz. Bulk packages. Steady market.
Resorcin	.. 5s. per lb. now quoted for good "White."
Salol	.. 2s. per lb. Unchanged.
Sod. Benzoate ..	.. 2s. 2d. per lb. Still in short supply.
Sod. Citrate ..	.. U.S.P. quality 2 mols. water quoted at 2s. 2d. per lb. for cwt. lots. B.P.C. quality 5 mols. water, 2s. per lb.
Sod. Hyposulphite—	
Photographic	.. £15-£17 per ton, according to quantity.

Sod. Salicylate	2s. 3d. for Powder, 2s. 4d. for Crystals. These prices show little profit to the manufacturers, and higher rates are expected in the near future.
Sod. Sulphite—	
Anhydrous	£27 10s.-£28 10s., according to quantity, f.o.r. London drums included.
Pea Crystals	£17-£17 10s. per ton, according to quantity.
Thymol	17s. to 19s. per lb., according to quantity. Much firmer.

PERFUMERY CHEMICALS

Amyl Acetate	2s. 3d.
Amyl Butyrate	8s.
Amyl Salicylate	3s. 3d.
Anethol (melting point 21°/22° C.)	4s. 6d.
Benzyl Acetate (from chlorine-free Benzyl Alcohol)	3s.
Benzyl Alcohol free from chlorine	3s.
Benzaldehyde, free from Chlorine	3s.
Benzyl Benzoate, 19.5°C.	3s.
Cinnamic Aldehyde—	
98/100% Natural	14s. 9d.
Coumarin	12s. 6d.
Citronellol	22s. 6d.
Citral, 100%	10s. 6d.
Ethyl Phthalate	4s. 3d.
Eugenol, 100%	11s.
Geraniol (Palmarosa)	30s.
Geraniol	5s. 6d.-12s. 6d.
Heliotropine	5s. 9d.
Iso Eugenol	18s. 6d.
Linalol ex Bois de Rose	21s.
Linanlyl Acetate	22s. 6d.
Methyl Benzoate	8s. 6d.
Musk Xylol	8s. 9d.
Phenyl Ethyl Acetate	10s.
Phenyl Ethyl Alcohol	17s. 6d.
Rhodinol	45s.

ESSENTIAL OILS

Anise Oil, Red Ship Brand	2s. 1d.
Bourbon Geranium Oil	26s. 6d. for shipment.
Cananga Oil, Java	9s. Firm.
Cinnamon Oil, Leaf	4d. per oz.
Cassia Oil, 80/85%	8s. 6d.
Citronella Oil—	
Java, 85/90%	3s. 6d.
Ceylon	3s. 3d.
Clove Oil	7s.
Eucalyptus Oil, 70/75%	1s. 8d.
Lavender Oil, Mont Blanc, 38/40%	12s. 6d.
Lemon Oil, Spot	2s. 11d. New crop for shipment 2s. 9d.
Orange Oil, Sweet, Spot	9s. 6d. New crop for shipment 8s. 6d.
Otto of Rose Oil—	
Anatolian	24s.
Bulgarian	26s.
Palma Rosa Oil	17s. 6d.
Peppermint Oil—	
English, Mitcham	80s.
Wayne County	13s.
Japanese	7s.

TRADE NOTES

Ceylon in 1921

The year was marked by serious depression in the Colony's chief industries—tea, rubber and plumbago. The rubber situation improved slightly, however, in the second half of the year and, by exercising great economy, estates were able to continue production. Greater attention was paid to preparation owing to the low prices of rubber, especially for mildewed or rusty sheet, and the manufacture of rubber goods has been initiated. Most estates continue to tap on alternate days, but the use of the 3-day tapping system is increasing. The coconut crop was good and exports of cardamoms, cinnamon, citronella oil and kapok increased. Plumbago mining continued to be in an unsatisfactory state and the production of mica was small. About 61 tons of monazite sand was produced at Bentola and trials of dressing plant show that at present prices it should be economically possible to treat the extensiv low-grade deposits of "black sand" on the west coast of the island. Imports were valued at Rs. 260,897,161 and exports at Rs. 256,600,413, the share of the United Kingdom being 25·32 and 46·22 per cent. respectively.—(*Col. Rep. Ann., No.* 1137, 1922.)

Dyestuffs (Import Regulation) Act, 1920

The Board of Trade has received the following statement relating to applications made during the month of January, 1923, for licences under the Dyestuffs (Import Regulation) Act, 1920, from the Dyestuffs Advisory Licensing Committee. Similar monthly statements will be issued regularly in future.

The total number of applications received was 562, of which 473 were from merchants and agents. These were dealt with as follows:—

Granted, 359 (of which 340 were dealt with within one week).

Refused, applicants being referred to British makers (British equivalents being available), 94 (of which 93 were dealt with within one week).

Referred to Reparation Supplies, 53 (of which 53 were dealt with within one week).

Outstanding on January 31, 56 (most of these were applications received on January 31, and 38 were dealt with on February 1).

Of the total number, 562, of applications received, 412, or 73 per cent., were dealt with within two days.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, MARCH 2, 1923 No. 9

EDITORIAL

A NUMBER of circumstances have directed our thoughts to the Royal Society: a reference to Dr. Benjamin Franklin in the communication (the latest, not last) from the Rev. B. V. White, the bicentenary of the death of Sir Christopher Wren, and the announcement of the candidates recommended for election by the Council of the Society. There is no doubt that every now and then someone criticises the Royal Society and blames it for having no constructive policy. Such criticism has been indulged in for upwards of two hundred years, and our attention was recently drawn to the *Tatler*, in the year 1710 (No. 236), which stated that the Fellows seemed "to be in a confederacy against men of polite genius, noble thought and diffusive learning." Criticism of this type, and of other types of more recent date, may well continue for another couple of hundred years, for there seems to be no reason why the Royal Society should not flourish, root and branch, for ever. Time was when Science was so elementary that a man of polite genius and diffusive learning might be justly entitled to election to the Society. In the twentieth century diffusive knowledge is readily acquired and not highly valued. It is the intensive culture of the mind in one special domain of learning, which now advances knowledge, and is properly honoured by admission into one of the most aristocratic and exclusive assemblies in the world. To expect constructive policies of a body which comprises the most learned and ingenious mathematicians, geologists, physicists, chemists and biologists of the day is as reasonable as to expect diplomacy from the conclave of the Knights of the Garter, or a scheme of military value from the united wisdom of the Lords Lieutenant of the Counties. The Fellowship of the Royal Society is the highest honour which Science can bestow and those who attain that distinction are chosen by those who are best fitted to judge of the merits of the many candidates who are available. We must be satisfied with such a distinction, and not expect the Fellows to be, in addition, men of the world, pioneers of reform, or contrivers of large schemes which affect the application of science in general to the benefit of mankind.

* * *

Our knowledge of the properties that characterise many of the most widely-used commodities is surprisingly inadequate. Agreement seems hard to find even on subjects such as standards for our food supply, despite their importance to the community and the perfection of modern methods of investigation. Agriculture, formerly an "Art," has long been ranked as a "Science," and technical publications devoted to its furtherance are legion, yet many problems of fundamental importance to it still await resolution. An instance of this is provided in the account, published in this issue, of the "National Milk Conference," from which we gather that problems such as the composition of milk, the effects of sterilisation on its vitamin content, and methods of preventing contamination are subjects of keen controversy. That there is controversy is all to the good, but it is regrettable that there is the need for it, for it implies an absence of precise knowledge. We are glad to support our contributor in urging that these are problems for immediate consideration by the chemist. A problem of the milk industry which still awaits solution is the utilisation of the whey, produced in making cheese, as a source of lactose. Some attempts were made to establish this industry during the war, but they have only partially been successful. The establishment of lactose production on an industrial scale in this country is most desirable, and there are probably many other foods and food products which deserve close attention by chemists in the interests of the community. Some of the problems involved in these require immediate study.

* * *

We recently read some advice to authors of learned books and writings; they were directed to rewrite their articles three or four times, making improvements each time. Such procedure, such leisure, such an oblivion of space and time filled us with envy. The distinguished man who gave such advice wrote, nay writes, for he is with us yet, in a world where weekly journals, dispensing scientific information to what is, in the main, a learned and critical body of readers, are unknown. What standard of style should we aim at? To what level should we never descend? These are the two questions which only our readers can answer for us. We can merely put forward some factors which complicate the situation and make the problem more difficult. How often have we, or some skilled contributors, written some elegant contribution, carefully modulated, nice in expression and having only one fault, that of being ten or a dozen lines too long. We expostulate with the unreasonable printer who refuses—just for this once—to enlarge his column. "We cannot cut this down without spoiling it," we plead. "We can," answers the printer, ominously seizing a large pair of scissors. As for rewriting an article three or four times, this may do for the *Borneo Advertiser* or *Equatorial Herald of Science*, where presumably time is not of the essence of the contract, but here in London, where overtime must be considered and where a few hours' delay may be fatal, some less perfection must be attempted. Simplicity of language, the use of no obscure words where easy ones will do, plain intelligible statements of the case, these are the essentials. Sometimes the author likes to introduce a new phraseology, some fresh terminological excrescences, a new species of shorthand which he and a few others understand. Our science has already enough hard phrases and sesquipedalian words. We shall be more effective as chemists, appeal more to the imagination of our fellow-citizens, make ourselves more felt in the world if we can get into the way of thinking, speaking and writing in words which many of those we address can understand. But do not look for sustained eloquence in our pages; on the other hand, we invite our readers to protest vigorously against bad grammar, involved and ambiguous sentences, or needless obscurity. We feel that we should set a reasonably high standard in the art of bringing scientific information before the notice not only of the expert but also of a large number of readers who prefer comparatively simple words.

* * *

The opening of the new Research Laboratories of the General Electric Co., Ltd., may easily prove to be an event of considerable importance. The buildings themselves are ample and well equipped. The total floor area is about 80,000 square feet, and as the enclosure contains four acres, there is room for additional buildings if occasion arises. So ample a laboratory, run by a company with the experience and resources possessed by the General Electric Company, has potentialities of usefulness which can only vaguely be imagined. The laboratories of the Western Electric Company in New York and of the General Electric Company in Schenectady are probably the two best-equipped Research Laboratories in the United States. At the latter, which is under the direction of Dr. Whitney, Langmuir has done all his work, and his investigations have already attained world-wide fame and are found to be of first rate importance. Research of this quality, likely to prove of great value to the world at large, and in particular to the company responsible for it, is very frequently not very intimately connected with the smaller industrial problems which confront a business organisation. We have confidence that so far-seeing a company as the General Electric Company will not be unduly critical of investigations which do not show some immediate commercial value. First-class research, the kind which produces the telegraph, the wireless developments, the telephone, electric lighting, X-ray industries and such great discoveries, is conducted by men of genius; these are capricious, have ideas of their own, and their work is spoilt or prevented if they are tied down too closely to the investigation of problems set by a board of directors. The speeches made by Mr. Hugo Hirst, the chairman of the company, and by Lord Robert Cecil were interesting and appropriate. That of Sir Joseph Thomson was particularly so. As he said, the capacity for the highest kind of research was not common, and it is only an exceptional man who can make adequate use of such an opportunity as the new laboratories provides. If in the large staff which will no doubt be placed in charge of the work there is one man of outstanding power, this is all that may be expected, and if he is allowed and encouraged to pursue the ideas which his fancy dictates, some highly interesting and commercially valuable discoveries will in time be forthcoming. The nation should be grateful to the General Electric Company for their enterprise, and we shall be much surprised if in ten years the shareholders are not equally grateful.

GASOLINE TEN YEARS HENCE

By **RALPH H. McKEE**

Professor of Chemical Engineering, Columbia University; Chairman, American Section, Society of Chemical Industry

Everyone has a general idea of what present-day motor fuel or gasoline is, and yet there is some difficulty in defining it in a way which is altogether clear. For the present need gasoline may be defined as a hydrocarbon distillate, generally a petroleum distillate, 90 per cent. of which boils below 374° F., and all of which boils below 437° F. It has a density of less than 50° Bé. To be commercial gasoline it must, in addition, have but a light colour and be free from certain types of impurities.

Straight Distillate

Twenty years ago all the gasoline used was obtained as the light low-boiling distillate from crude petroleum. This distillate, which might be called crude gasoline, was then chemically treated to give the refined gasoline. It is quite easy to make a good quality gasoline from such a quality of petroleum as Pennsylvania Petroleum, but when the Pennsylvania fields began to decrease in output and the lower quality oils from Canada, Ohio, the Middle West and the Far West came into the market, it was found that they did not give either as large a percentage of gasoline or a product of as high a quality as had been given by the Pennsylvania oil. On the other hand, the demands for gasoline, due to the growth of the automobile industry, were increasing.

The effect of this change of the commercial situation was that lower grade gasolines began to come into the market. These were lower grade in that they carried some of the higher boiling kerosene fraction, some colour and some of the unsaturated constituents, which give a stronger odoured product. Each phase of this lowering of the standard brought about distinct increases in the amount available, but even in these circumstances the demand has increased faster than the supply, and accordingly there have been attempts to use other products to supply the deficiency. These attempts have given rise to three new petroleum products—casinghead gasoline, natural-gas condensate and cracked gasoline, as well as substitutes quite different from petroleum products.

Cracked Gasoline

When a higher boiling petroleum of the type of low-priced fuel oil or gas oil is heated to a temperature of about 700° F., there is a decomposition of this oil with separation of carbon on the one hand and the formation of light boiling constituents of the type of gasoline and kerosene on the other hand. This process is known as "cracking," and the lighter of the commercial products made is known as cracked gasoline. Cracked gasoline carries up to 40 per cent. of unsaturated compounds. The automobile of a few years ago would not run well on present-day gasoline. Further, it is certain that the gasoline on the market is destined to show an increasing content of unsaturated compounds, and we must look to the engine designer at least to keep up and even with the changes in the type of fuel available.

Casinghead Gasoline

Many an oil well gives at the same time considerable amounts of gas as well as oil. If this gas is examined, it is found to be formed in part by the evaporation of the same volatile constituents as are present in the liquid petroleum. If we condense the low boiling liquids from this gas, we obtain a very volatile gasoline. Gasoline obtained from the gas coming from the top of the casing of an oil well is called in the industry "casinghead gasoline."

Gasoline Substitutes

The requirements for gasoline are increasing year by year by very considerable amounts. In Canada and in the United States gasoline has been cheap and comparatively abundant. This has not been true the world over. We consider 50 cents an imperial gallon high, but most of the world would welcome gasoline at 70 cents a gallon, and call it cheap. Europe is using, and has been using as a motor fuel for some time, large amounts of benzol, obtained as a by-product from its coke and gas plants. Germany has been using a product called tetralin. Tetralin is obtained by the hydrogenation of naphthalene with hydrogen gas in the presence of nickel. It is a colourless fluid boiling at 205° C., freezing about 30° C. Its properties resemble gasoline and kerosene in fluidity, resistance to low temperatures and flash-point (79° C.—174° F.). In the motor it explodes smoothly and shows no tendency to "knock." On account of its low vapour pressure, tetralin must always be mixed with some more volatile fuel—*e.g.*, benzol. In Germany, the mixture most used has been equal volumes of tetralin, benzol and alcohol.

The Scottish shale-oil plants have been furnishing considerable quantities of a motor spirit from oil shale. Cuba has had a surplus of molasses, this molasses on fermentation giving alcohol, and extensive use has been made of this alcohol, not only to furnish visitors from the United States with a beverage, but also locally to replace to a considerable extent gasoline for automobile uses. Natal has also an abundant supply of alcohol from its waste molasses. Imported gasoline is quite expensive, and, accordingly, a product has been devised which goes by the name of Natalite, and has largely taken the place of gasoline in that part of the world. Natalite is a mixture of alcohol with about 45 per cent. of ether. In the United States we have had but one commercial attempt to supply a gasoline substitute. This is the "alcogas," put out by the United States Industrial Chemical Co., of Baltimore, this company being a subsidiary of the United States Industrial Alcohol Co.

Each of these substitutes has its advantages and disadvantages. Benzol and tetralin are decidedly cheaper than gasoline in Europe: but, on the other hand, they make it harder to start the engine, and the tendency towards formation of carbon in the cylinder is greater than with gasoline. Shale motor spirit of Scotland often runs 60 per cent. unsaturated, and, accordingly, it has a strong odour, is somewhat coloured, and cannot be stored for any considerable time without loss of quality. The alcohol products of Cuba and Natal, particularly when mixed with much ether, as in the case of Natalite, give trouble owing to their great tendency to make the engine "knock," and also some trouble due to the difficulty of obtaining them free from acetic acid. If acetic acid is present, there will be corrosion of the storage tanks, tank cars and the container tanks in the automobile. This corrosion and also the "knock" effect can be reduced and even avoided entirely by adding such material as aniline; but aniline is expensive. One does not want to add any considerable amount of a constituent costing $2·00 a gallon, and aniline cannot be had for less.

"Alcogas" is a more complex material than the substitute used in other countries. It consists approximately of one-third benzol distillate, principally benzol and toluol, a second third of alcohol products, alcohol and ether, and the remaining third of petroleum distillate, principally gasoline. The amount of ether required to start the engine easily varies according to the time of year. In winter 10 per cent., and in the summer 5 per cent., is all that is essential. This American gasoline substitute has a big advantage over ordinary gasoline in that the cylinders do not carbonise. This keeping of the cylinders clean means ordinarily a greater mileage per gallon than is obtained from gasoline—about 10 per cent. greater.

Future Demands

The petroleum requirements of the United States and of Canada are steadily increasing, the amount of the increase in the United States being approximately 50 million barrels a year. Part of this increase is due to the increase in fuel-oil requirements, but a large part is also due to an increase in the gasoline requirements. Apparently the gasoline requirement of the country is going to continue to increase and perhaps at an even greater rate than in the past.

The prospects for an increased supply of petroleum from American oil wells are nil. The investigations of the United States Geological Survey and the United States Bureau of Mines show quite definitely that the United States is approximately at its peak of production, and that within a very few years—probably within three years—the production of petroleum in the United States from wells will begin to fall off. Moreover, the Geological Survey calls attention to the fact that we should not expect to find any more large fields of petroleum in the United States. In other words, practically all the possibilities in the way of large petroleum fields in that country have been well prospected, and now we can calculate fairly closely what the production will be in the future. This calculation shows quite definitely that it is soon to decrease in amount. Canada is but little better off. In the past, as at present, the United States furnished approximately two-thirds of the world's production. But we are consuming more than we are producing; for example, in 1919, the United States imported 53 million barrels from Mexico, and, in 1920, 106 million barrels. In 1921 the importation was about 126 million barrels. In each year the United States has imported roughly about 60 per cent. of the total production of Mexico. Mexican and Texas fields are short-life fields; already they are in many places furnishing salt water instead of petroleum.

Shale Oil Industry

Four years ago a careful canvass of the situation showed that there was relatively little known about many of the fundamental factors upon which a successful shale-oil industry must be based. For example, almost nothing was known regarding the heat of reaction by which shale oil is formed from the organic material of the shale. Little was known regarding specific heats and latent heats, and nothing was known regarding the first reactions that control the formation of oil from the organic material. In the thought that this was going to be an industry of great importance to the country and the world, and that the knowledge of the fundamental factors on which the industry is based were essential to a proper development of that industry, the study of these fundamental factors was undertaken at Columbia University. A large part of this work is, of course, yet incomplete, but results have been obtained that are of the utmost importance. It would take a long time to discuss the methods used and the data obtained; now I can only give the results.

One of the most important factors entering into the design of a proper shale retort is that of the knowledge of amount of heat absorbed or evolved in the formation of shale oil from the organic matter of the shale. Dr. Lyder devised the first apparatus capable of directly determining this factor, and found that heat was absorbed in the process, and that the amount of heat absorbed was nearly the same for shales from different sections. This heat absorption amounted, in general, to about 450 calories per gram of oil and gas produced; or, in other terms, 160 B.Th.U. per pound of average shale retorted. This is a surprisingly low figure for such a reaction.

It has been generally thought that the organic matter in shale decomposed on heating to form petroleum products such as gasoline, kerosene, etc., as the primary products of decomposition. It has been shown by these researches that this is not the case, but that the primary product of the decomposition is a heavy solid or semi-solid bitumen, and that petroleum is formed by a secondary cracking process from this semi-solid bitumen. This secondary cracking process, by which petroleum products are formed, is a liquid-phase cracking process similar to the well-known phenomena of the cracking of heavy petroleum to give gasoline. Another surprising thing found was that the decomposition temperature of the shale to give the semi-solid bitumen was a quite definite temperature—about 410° C.

The investigations have also shown the incorrectness of the belief which has been held by many of those working on the developments of shale-oil manufacturing processes—that on heating gasoline is the first product formed; then, on a higher heating, kerosene; and, on still higher heating, lubricating oils, etc. In other words, it was shown that what happens on heating is that all these products are formed *simultaneously* by the cracking of the semi-solid bitumen first formed.

Oil shales vary among themselves not only in yield of oil per ton of shale, but also in type of oil, type and character of minor constituents, and also even in the gangue material which carries the organic portion.

Dr. Ralph T. Goodwin has lately shown that if oil shales are distilled at reduced pressure, there appears an intermediate product between the kerogen of the shale and the shale oil. This intermediate product is highly unsaturated; indeed, by the customary test of solubility in sulphuric acid, some samples show 100 per cent. unsaturation. On heating this product at atmospheric pressure, there is a marked decrease in the so-called unsaturated portion. The unsaturatedness dropped from 100 per cent. to approximately 50 per cent., and on a second distillation at atmospheric pressure the product may become as high as 80 per cent. saturated. This, I believe, is the first case where, on cracking an unsaturated hydrocarbon, saturated hydrocarbons are obtained. Further, it raises the question at once as to whether our ordinary conception of the cracking process is a correct one. In this work of Dr. Goodwin and myself we have further shown that the retorting of each shale is a separate problem, and that the problem of refining the oils begins with retorting the shales.

In Scotland oil shales are worked which furnish but 20 to 22 gallons of oil per ton of shale mined. In Canada and the United States we have large deposits of shales which are able to give a much higher yield of oil. The largest of these deposits are the Green River Shales of Colorado, Utah and Wyoming. There are also large deposits in New Brunswick and Nova Scotia, Nevada, California, Kentucky, Indiana and Ohio, and smaller deposits, though large enough for commercial exploitation, in many other portions of this continent. There are similar deposits in other parts of the world. Of those deposits which are likely to be exploited in the next decade we have variations in yield from 20 gallons to 60 or even 80 gallons per ton. The large deposits of better grade will give about a barrel (42 gallons) of oil per ton of rock. The character of oil produced in some cases is apparently a straight asphalt-type petroleum similar to California well petroleum. Other shales give a large quantity of paraffin wax of even better quality than that given by the best oil wells of Pennsylvania's history. It seems as if probably the average petroleum to be made from American oil shale will resemble most closely the petroleum obtained from the present mid-continent field, such as the Oklahoma oil.

It is not commonly appreciated how large these oil shale deposits are. If we consider only those oil shales which will furnish a barrel or more of petroleum per ton of shale (a barrel is 42 U.S. gallons), we have in the Green River Section alone, in known deposits, sufficient to furnish 64,000 million barrels of petroleum. This is an enormous amount. It is eight times larger than the total of the well petroleum that America has produced since Col. Drake drilled the first oil well in 1859 at Titusville, Pa. It is more than five times the total production of the world since well petroleum became commercial sixty years ago.

SHALE OIL PLANT

A shale oil plant, to be successful, must be able to handle cheaply and efficiently large quantities of oil shale, distilling it to get the crude oil and ammonia, and then crack and refine the crude oil to give a motor spirit useful commercially. The Scottish plants do this, excepting that they devote considerable attention to the recovery of paraffin wax, and it is only the oil left after the wax recovery that is distilled to give lubricating oils, gasoline and burning oils, or is cracked to give shale gasoline.

The Scottish shale retort is a retort of vertical pipe type. When we attempt to handle Canadian or American oil shales in this retort we find that they give trouble, owing to the pieces of shale sticking together and sticking to the sides of the retort. This caking of the shale lumps stops the passage of the shale through the retort. For use on most of these shales, it is quite apparent that we must either modify this Scottish retort or devise retorts on new lines. The Scottish retort is designed with the dual purpose of recovering ammonia from the shale and of obtaining oil. With the American shales we have larger amounts of oil but ordinarily distinctly less ammonia than is produced from the Scottish shale. In other words, the retort to handle the American oil shale *properly* must be one which gives its attention primarily to the production of oil in quantity and of acceptable quality, and only secondarily to the production of ammonia. There are more than a score of retorting schemes which have been proposed by various American inventors. None of these has yet produced shale oil in large quantities. The most completely developed plant and process is that of the Catlin Shale Products Co., at Elko, Nevada, which has a plant which has produced approximately 100,000 gallons of shale oil. A small commercial refinery is just completed, and the first shale oil and shale gasoline to be marketed in quantity in America is coming from this plant. There are probably several other types of retorts which have been proposed for use in distilling oil shale which would, if given proper technical study and trials, develop into commercial processes. At present, few, except the inventor himself, believe that any one of these retorts is certain to be practicable when used on a large scale.

It is only within the last three years that serious attention has been given to the question of the development of a proper type of retorting still, and we have no reasons to think but that, well before the same length of time from now has passed, we will have succeeded in obtaining a retorting scheme which can handle with low labour costs efficiently and economically Canadian and American oil shales.

I have earlier shown you that the American demands for petroleum are increasing at the rate of about 50 million barrels a year. If this continues, it will require each year 75 new plants, each handling 2,000 tons of oil shale a day and representing an investment of a million dollars each, to give sufficient oil to meet simply this yearly increase in demands for petroleum. We have no other prospect which promises to furnish even a minor part of this demand. In other words, we have reason to look forward to a very large chemical manufacturing industry which will give us gasoline in quantity from oil shale and which will rank with our largest manufacturing industries in its labour and capital requirements and in value of output.

SCIENCE

"The desirable treasure of wisdom and science, which all men desire by an instinct of nature, infinitely surpasses all the riches of the world; in respect of which precious stones are worthless; in comparison with which silver is as clay and pure gold is as a little sand; at whose splendour the sun and moon are dark to look upon; compared with whose marvellous sweetness honey and manna are bitter to the taste." *Richard de Bury.*

PREFERENTIAL OXIDATION IN PRESENCE OF CATALYSTS

REX FURNESS

THE substantial reality of the success of applied catalysis during the last two decades is small in relation to its promise for the future. The "triumphs of applied catalysis" is the phraseology of platitude, and it is scarcely necessary to refer to the processes, such as oil-hydrogenation, ammonia synthesis and oxidation, sulphur-dioxide oxidation, acetic-acid production, etc., in order to show the wider outlook rendered possible by the use of suitable catalysts in industry. To a large extent, however, the reactions underlying these processes are simple, and when a suitably efficient catalyst has been discovered, a large step has been taken towards commercial realisation and economic soundness. Broadly speaking, one reaction and one only, is possible in these cases, and the problems associated with its acceleration are essentially more simple than when two or more reactions can take place, and it is a question of accelerating one and retarding the other or others. Preferential catalysis has scarcely yet been touched in successful industrial operation in comparison with simple-reaction catalysis, but presents almost unlimited possibilities.

Preferential catalytic oxidation, too, presents a further complicating feature, in that—with organic compounds—the products of the undesired, but easily attained complete oxidation, are worthless. Thus, the partial or preferential oxidation of benzene will result in the production of maleic acid, but the full oxidation or combustion of the hydrocarbon leads to the formation of carbon dioxide and water. Without minimising the engineering problems, which have had to be solved in, say, ammonia synthesis, it is clear that great difficulties stand in the way of the successful application of catalytic preferential-oxidation processes in practice.

In the study of catalysis in general, no theory of universal applicability can yet be advanced. Even in many specific problems, practical technical operation is well ahead of theory, and in the study of preferential catalysis, practice, though limited, is perhaps still further ahead. It is true, however, that much effort is being made to "blaze a trail," witness the experiments of Rosenmund and Zetzsche. For example, by suitably influencing the catalyst and using benzoyl chloride as a starting material, any member of the following series may be made the chief reaction product, namely, the corresponding ester, hydrocarbon, aldehyde, alcohol or ether. Again, by partial and controlled poisoning of the catalyst, specific and different products may be obtained from one starting material. Alcohol may be made to give aldehyde, ether or ethylene, according to how far the catalyst has been poisoned by the presence of foreign substances.

Much attention has been given to preferential and partial catalytic oxidation in the technical press, and several processes have passed the experimental stage. The production of maleic acid from benzene, by catalytic oxidation under careful control in the presence of oxides of vanadium or molybdenum, and similar problems, such as the oxidation of naphthalene to phthalic anhydride and acid, of anthracene to anthraquinone, etc., have already been reviewed by the writer (*cf.* J., 1921, 307 R).

The preferential oxidation of carbon monoxide contained in hydrogen so that the whole of the former might be converted to the easily soluble carbon dioxide, and the simultaneous combustion of the latter to form water reduced to a minimum, has been the subject of patent claims, but a study of the work of Rideal (*J. Chem. Soc.*, 1919, 993; *J.*, 1921, 307 R), in this connexion shows that little hope of commercial realisation can be entertained, if known catalysts are to be used.

The attempts to oxidise hydrocarbons of the paraffin series—and mineral oils in general—to fatty acids have also been reviewed (*J.*, 1921, 62 R), and little has since appeared to indicate that the project is substantially nearer universal applicability to mineral oils, or to full technical realisation.

There are, however, two processes which merit special consideration to-day. The first, namely, the partial oxidation of sulphuretted hydrogen contained in fuel gases, to sulphur and water, with little or no formation of oxides of sulphur, will provide a process widely applicable for purifying gas, and the scattered results of experimentation are discussed below. The second process, in which partial oxidation of hydrocarbons is effected, and marked preferential catalysis claimed to occur, is said to be under trial on a large scale. This process suggests the possibility of producing a variety of useful industrial products, including resins, soaps, lubricating oils, froth-flotation oils, fuels for internal-combustion engines, etc.

OXIDATION OF SULPHURETTED HYDROGEN TO FREE SULPHUR

Most industrial gases used for fuel purposes contain sulphuretted hydrogen in more or less considerable quantities. Water gas, hydrogen, illuminating gas, etc., must be entirely or substantially freed from this impurity before application in industry, or for heating and lighting in the home. The present old established method, involving the use of hydrated iron oxide in purifier boxes, is slow, cumbersome, and—in comparison with quicker catalytic methods that readily produce free sulphur—expensive, the hydrated iron-oxide process is, of course, catalytic, but very large quantities of the catalyst are required in relation to the amount of gas purified.* Two main endeavours have been made to discover processes which allow of a much greater throughput per unit of space and time. These may, for convenience, be designated the cold process and the hot process.

Cold Purification.—The reaction upon which the removal of sulphuretted hydrogen depends is, in general, the following: $H_2S + O = H_2O + S$. This reaction may be accelerated catalytically, of course, the cycle of reactions occurring in the ordinary iron-oxide purifiers, show that the oxide acts as a catalyst.

Much attention has recently been given to the possibility of using highly active charcoal as catalyst for the above reaction. Thus, the Baeyer Co. claims that the presence of active charcoal greatly increases the reaction velocity, but does not lead to the formation of oxides of sulphur. A gas containing 12 g. hydrogen sulphide per cb. m. may be completely purified by means of charcoal contained in a space of two cubic metres, at a speed much greater than that commonly attained in the old iron-oxide treatment. About 40,000 to 50,000 cb. m. of gas can be treated before the charcoal becomes so saturated with sulphur that this requires extraction so that the reaction may proceed. The density of the various forms of activated charcoal—produced primarily for poison-gas mask fillings during the war—varies considerably, but the charcoal retains approximately an equal weight of sulphur before extraction becomes necessary.

The process has many variants, but in general may be said to follow these lines: Gas containing hydrogen sulphide is freed from tar and naphthalene as far as possible and the bulk of the ammonia is also removed. A slight trace of ammonia acts catalytically, and enables the reaction to take place rapidly at ordinary temperatures. The oxygen concentration is adjusted according to the sulphuretted hydrogen present in the gas, and the mixture is passed over the active charcoal, contained in vessels capable of being heated or cooled. The speed of passage varies with the activity of the charcoal, sulphuretted-hydrogen content, amount of sulphur already formed in the charcoal mass, temperature, and catalysts or catalyst-poisons present. The temperature should be maintained at a low level, although the reaction is exothermic. The charcoal-containers may be arranged in series or parallel, and worked until the sulphur content has reached a pre-determined amount or a definite percentage of hydrogen sulphide has been removed from the gas. The sulphur is then extracted by means of a suitable solvent, carbon disulphide, mono- or dichlorbenzene, tetrahydronaphthalene, etc. After a suitable period of extraction, the solvent is removed and the charcoal, after being washed and dried in a current of hot gas free from hydrogen sulphide, can be used again. The sulphur is easily obtained from solution by crystallisation or evaporation. One of the difficulties of the process is stated to be the extraction of the sulphur, but improved constructional details will remove this trouble. It is, however, interesting to note the process of the Badische Anilin-und Soda Fabrik for the removing of the sulphur deposited. A solution of ammonium sulphide, produced in recovering the sulphur, is distilled in the presence of an inert electrolyte, *e.g.*, sodium chloride, to facilitate the deposition of sulphur and the liberation of ammonia. The aqueous ammonia-solution passes from a condenser to the vessel containing spent charcoal charged with sulphur. The solution draining from the charcoal passes continuously to the still, until the extraction of the sulphur, and deposition from the ammonium sulphide solution produced, is complete. The charcoal is washed, dried, and is then ready for re-use in the catalytic reaction between sulphuretted hydrogen and oxygen.

---

* Other processes are also being studied, in which a liquid medium is utilised as absorbent or reagent. Reference need be made only to the use of glycerin under pressure, of dyestuff solutions, alternately reduced by sulphuretted hydrogen and oxidised by air, and of sodium-carbonate solution. The Koppers Co. (U.S.A.) is purifying 25 million cubic feet of gas per day by simple treatment with sodium carbonate solution, followed by passage through iron-oxide boxes to effect the small amount of final purification required. The solution is regenerated continuously by oxidation with air. This process is finding favour in American practice.

The process of purification using charcoal as catalyst is open to several criticisms. The cost of highly active charcoal is high, and although relatively small quantities are required in comparison with the iron hydroxide necessary in purifier boxes, the capital outlay is not small. The objection should be met in the near future since active charcoals should be produced much more cheaply than at present. A second objection, noted in the Alkali Inspector's Report, 1921, is that oxides of sulphur are produced, in addition to free sulphur. The difficulty of removing small amounts of these gaseous oxides, even with alkaline solutions, is well known, and unless complete preferential catalysis can be effected, a serious difficulty will remain. At low temperatures, and with sufficiently active charcoal, however, the reaction is specific in the direction of free sulphur formation, and an excellent case of catalytic preferential or partial combustion is indicated.

Illuminants are absorbed by the catalyst, and ethylene, benzene*, etc., are retained by the charcoal. These are recoverable, and in any case, only diminish the quality and saleability of the gas by the corresponding calorific value. With many industrial gases, no such difficulty exists, for illuminants are entirely absent.

The value of a successful process is obvious. A high-speed reaction, easily controlled and involving little attention in practice, yielding pure sulphur for sale at a profit, is in marked contrast with present processes of gas purification.

Little is yet known of the mechanism of the reaction. The highly adsorptive and absorptive nature of activated charcoal is well known, as is the increased concentration of oxygen and sulphuretted hydrogen upon the surface of the catalyst prior to the reaction. Marshall has recently suggested that oxygen combines with the carbon in the surface layers of the charcoal. Such deductions from a consideration of the phenomena of heat evolution, tend to support an intermediate-compound theory of reaction, but the matter has not been sufficiently studied to allow of explanation being definitely advanced Practice is, as stated above, well ahead of theory, and many companies and individuals have taken out patents covering the process, described in general type above. Thus, the Baeyer Co., Meister Lucius und Bruning, the Badische Co., Naef, Schumacher, and others have described slightly varying methods, all employing activated charcoal as catalyst.

Hot Purification.—Sulphuretted hydrogen is burned selectively or partially in the Chance-Claus kiln, free sulphur being produced. The same catalysts cannot, however, be used in purifying gas from sulphuretted hydrogen. Above 200° C., the reaction $2H_2O + 3S = 2H_2S + SO_2$ may occur, and oxides of sulphur pass into the exit gas. In gases which contain carbon monoxide—coal gas, water gas, and other industrial gases—another reaction is possible, as Evans has recently pointed out : carbon oxysulphide is formed, and is more troublesome than the original hydrogen sulphide.

A hot-purification system requires the discovery of a catalyst which will oxidise sulphuretted hydrogen specifically to sulphur, according to the equation, $H_2S + O = H_2O + S$. Many compounds have been tried, but as yet none appears to act preferentially in full degree, but it is inadvisable to assume that finality in the matter has been reached.

The advantages lying in a successful process are again obvious—a high-speed reaction, the deposition of free sulphur, or its removal from the catalyst by distillation in the gas stream, lower capital and labour charges, etc.

The reaction is exothermic, and with efficient heat-exchange, little, if any, additional heat should be needed, whilst the calorific value of fuel gases, should be but little reduced, if at all.

As typical of efforts being made in the direction of hot purification, the process of Lemon (U.S.P. 1,317,583), may be noted, but, as the catalyst suggested is not sufficiently selective in nature, and some traces of sulphur oxides are formed, it is improbable that a wide application will be possible. The process, involving scrubbing towers for the gas after reaction, would undoubtedly be more costly than the present iron-oxide box treatment. It, however, indicates the potentialities of the hot purification system, in the event of a preferential oxidation being achieved, for in installation and working charges it would easily oust the older systems.

---

* Engelhardt has recently described the application of activated charcoal for the stripping of benzene from coal-gas at the Cologne gas-works.

The catalyst suggested for the process is pumice, porous pot, or other porous substance, and the gas mixture containing sulphuretted hydrogen and oxygen in equivalent proportions, is treated at about 300° C. The exit gases, possibly carrying sulphur vapour, pass to a scrubber, wherein the sulphur oxides produced are retained. The calorific value is but little diminished by the treatment. At higher temperatures or in the presence of supported catalytic platinum or nickel catalysts the reaction tends still more towards the formation of sulphur oxide, and a catalyst that induces the rapid formation of sulphur at a low temperature, preferably below 200°C., is urgently needed.

Oxidation of Hydrocarbon Oils

The attempts to produce fatty acids by the oxidation of liquid paraffin wax and hydrocarbon oils have been referred to. A new process, patented in many countries, has recently been described by James (*Chem. Met. Eng.*, 1922, **26**, 209). A reaction in the vapour phase is catalysed at high speed by metallic oxides, etc., and although preferential oxidation in one specific direction is not apparent, it is probable that attempts will be made to find a catalyst which will act in this way. The germ of the preferential-oxidation process is apparent, because in presence of one catalyst, uranium oxide, oxidation is carried to the stage at which aldehydes are formed, whilst molybdenum oxide catalyses the formation of aldehydic acids.

An aliphatic hydrocarbon oil—fuel oil, gas oil, or a sulphur-containing or unsaturated oil—is vaporised, and passed through three catalytic screens, 1 cm. in thickness, the requisite amount of air being added before each screen. The temperature may vary, but is kept as low as possible, the temperature of the catalyst being controlled by immersed cooling pipes.

In a trial on a semi-large scale, 80 per cent. of liquid product was obtained, consisting of 30 per cent. aldehydic acids, 20 per cent. high aldehydes, and 50 per cent. of oxidised oils, alcohols, lower-boiling hydrocarbons produced pyrolytically, etc.

The products offer a distinct possibility of commercial application, for the acids may be converted into calcium soaps, which, mixed with the "congeneric oil" fraction of the product, provide a good lubricating grease. Sodium soaps prepared indirectly from the calcium soaps, are of good colour. If the acids are treated with caustic soda directly, resinification occurs, and the liberated resinous compounds may be used in cheap varnishes. The acids, or the whole liquid product, may be used as a froth-flotation oil, and excellent results are claimed. From the "congeneric oil," an oxidised kerosene may be distilled, and used as a fuel for internal-combustion engines, or as a starting material for "cracking" operations, whilst higher fractions, containing oxygen, can be used to advantage in compounded lubricating oils, much in the same way as free fatty acids are added to mineral oils in the Wells and Southcombe ("germ") process.

It is unnecessary to dwell on the uses of the products, for it will be apparent that they can yield useful commercial materials. It is already known that different products can be obtained by varying the conditions of the reaction and the catalysts. With increasing knowledge of the composition of mineral oils and the development of catalysts that will accelerate specific partial-oxidation reactions, the production of definite substances of commercial use will become possible. The range of products from the many hydrocarbons of mineral oils is extremely wide, and catalytic preferential-oxidation in this field alone is of wide economic importance. The isolation of particular hydrocarbons, the production of definite products from them, and the utilisation of the remaining hydrocarbons as fuel, power spirit, etc., instead of utilising the whole mineral oil as fuel, will be a notable step in the development of a more scientific petroleum industry.

THE GOVERNMENT WOOL-DISINFECTING STATION

THE Departmental Committee on Anthrax in their report to the Home Office pointed out that preventive measures, short of destruction of the organism causing anthrax, could never be successful. The Committee accordingly put forward a scheme for establishing a central disinfecting station under Government control, and recommended the adoption of a method of disinfection, which had been devised by the Committee after prolonged enquiry and experiment and had been reported on favourably by the late Professor Délépine and subsequently by Dr. A. Eastwood, Bacteriologist to the Ministry of Health. The Government adopted the proposals and introduced in 1919 the Anthrax Prevention Act, giving power to make Orders in Council prohibiting the importation of animal products likely to be infected with anthrax, unless they are disinfected on arrival. It also established at Love Lane, Liverpool, the Government Wool-disinfecting Station (Home Office), which has now been operating for about a year. The following account of its work has been prepared by Mr. G. E. Duckering, Director of the Station.

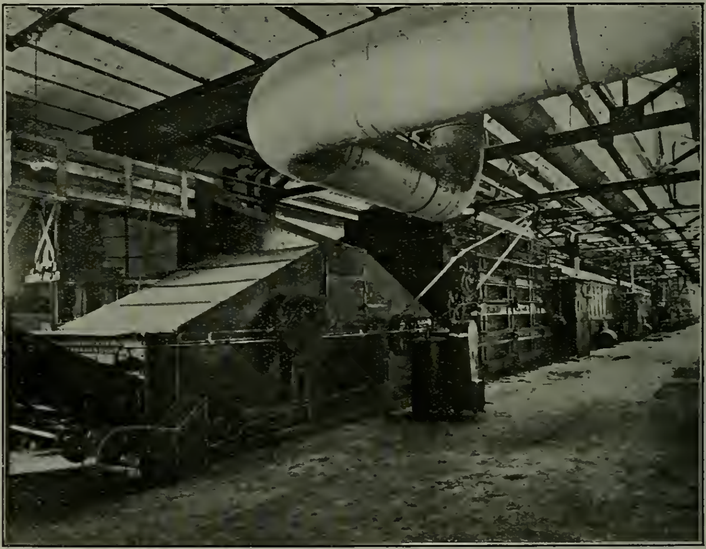
The disinfection process is arranged in seven stages, the machinery for opening the bales of raw material, feeding the material into the machines, disinfection, drying, cooling, and rebaling, being designed to permit all the stages to be carried out in sequence as one operation, without direct handling of the material by the workmen. The stages are as follows :—

Stage 1.—Hydraulically pressed bales as imported are placed on the moving platform of a feeding and opening machine and the steel bands and canvas covers removed. The material itself is not touched, but travels on the platform into the machine, where it is opened and delivered into the first process machine.

Stage 2.—In the first process machine it is submitted for 10 minutes to the action of a dilute alkaline solution at 102°F. in order to remove the albuminous matters by which the anthrax spores are protected. It is then squeezed through rollers and delivered into the second process machine.

Stage 3.—The material is here acted on for 20 minutes by a dilute alkaline soap solution at 102°F. in two successive baths, the purpose being to promote a condition of the spores in which they can be killed with comparative ease. This stage is essential to the process and it possesses the advantage that it also cleanses the material completely. The wool then passes through rollers into No. 4 process machine.

Stage 4.—In this state the actual disinfection is carried out, the material passing through two successive baths (with rollers between) of a 2·3 per cent. solution of formaldehyde at 106° F. It then passes through rollers and is blown by air into a drying machine (*Stage* 5), discharged into a cooling machine (*Stage* 6), blown by air into the charging box of a baling machine, then baled into hard pressed bales of about 320 lb. (*Stage* 7). The material remains 10 minutes in each process bath, and 20 minutes in the drier and cooler, the whole process of disinfection from opening the bale to rebaling occupying, roughly, 90 minutes. Although the material itself is not handled throughout the process, in order further to safeguard the workmen, overalls are worn and sterilised weekly, exceptionally good lavatory accommodation is provided, and the workers take a bath daily.



STERILISATION OF WOOL

General view of Disinfecting Machine from delivery end

Under the Anthrax Prevention Act an Order in Council was made which came into force on June 1, 1921, under which all wool and animal hair imported from or through Egypt, and all East Indian goathair, are required to be disinfected. The imports of these materials, however, fell off very greatly in 1921 and efforts were made to induce voluntary sending of material for disinfection. The disinfection of material voluntarily sent is now a growing branch of the work carried on in the Disinfecting

Station. The following table shows the quantities of different materials disinfected in the period from July 4, 1921 (the date on which the Station began work) to March 31, 1922, and from the latter date to September 30, 1922 :—

Output of Disinfecting Station

MATERIALS	Period July 4, 1921, to March 31, 1922 Lb.	Period April 1, 1922, to Sept. 30, 1922 Lb.
Compulsorily disinfected :—		
Egyptian wool	310,401	182,509
East Indian goathair	190,444	402,049
Voluntarily sent for disinfection :—		
East Indian wool	32,583	25,241
Persian wool	18,194	60,117
Alpaca	1,059	17,228
Mohair	2,924	5,948
Horsehair manes and cow tail hair	8,013	14,375
Goathair	10,034	569
Other materials	8,440	—
Totals ..	582,092	708,036

The introduction of the scheme of compulsory disinfection of a staple raw material like wool is, of course, a great innovation, and it is, perhaps, not surprising that it gave rise to apprehension and much uncertainty in the wool trade partly from the fear of damage to the material and partly because the material is taken out of the ordinary routine and altered in some respects beyond recognition. The result of this, coupled with the great trade depression, was that the volume of imports was much reduced during the first nine months of the operation of the scheme. Gradually, however, confidence in the method of disinfection and in the procedure adopted for handling the numerous lots of materials belonging to different owners has been established, and since the beginning of June the Station has been kept constantly employed, and the imports are returning to pre-war volume.

The conditions which must be rigidly controlled in order to secure disinfection are : (*a*) Strength of solutions ; (*b*) temperature of solutions ; (*c*) time of exposure to solutions ; (*d*) temperature of drying. This control is secured by constant tests. These tests (except as to strength of solutions) and the maintenance of the proper conditions are carried out by the man in charge of the machines, who takes thermometer readings hourly and records them in a report which is made daily showing the identification marks of the lots of material, weight of material fed in per hour, quantity of formaldehyde added per hour, temperature of solutions in each machine and of air in the drier, weight of material delivered from the machines and certain other details. From this daily report the conditions during disinfection of any lot of material can be ascertained at any time subsequent to its disinfection. The conditions of disinfection are independently checked by the works chemist, who also makes analyses of the solutions hourly and records all his results in an independent report, which can be compared with, and used to check, the machine minder's report. In addition bacteriological tests are carried out to ascertain the efficiency of the sterilisation.

A high output is essential, and in order to cover working costs an average output of at least 40,000 lb. per week must be maintained. This average weekly output can now be attained on a working day of eight hours, so that provided the imports of the scheduled materials, together with the quantity sent voluntarily for disinfection, are sufficient to keep the Station fully employed, it should be possible to cover running expenses. For the charge of 1½d. per lb. of disinfected material the services performed at the Disinfecting Station are disinfection, cleansing of the material, and baling. Some prejudice has been shown against disinfection, and this is not yet entirely dissipated. Nevertheless, the condition of the material after disinfection, the freedom of disinfected material from regulations, and the absence of risk of disease, are gradually diminishing such opposition as there was to the scheme, and the time is not far distant when disinfection will be welcomed for its own sake apart from compulsion.

* * *

The following account of a test on a suggested method of disinfecting wool by means of ultraviolet rays has been extracted from a report made by Mr. Duckering, Director of the Wool-Disinfecting Station, to the Home Office.

In December, 1921, reports were published in the Press stating that two Liverpool investigators had discovered that anthrax spores in bales of wool could be destroyed by subjecting the bales to the action of rays from a mercury-vapour lamp, the rays being described as ultraviolet rays. On inquiry it was found that the investigators proposed the use of both X-rays and the rays from mercury-vapour lamps and they claimed that the method, if applied in a warehouse, would sterilise the whole of the material in the warehouse within two minutes.

The Anthrax Committee was strongly pressed to carry out experiments to test the efficiency of the proposed method of disinfection. It was pointed out that if efficient it would be cheap and, what is more important, that the bales of wool could be sterilised in bulk without having to open them or in any way interfere with the material.

It has been long known that ultra-violet rays have some bactericidal effect, but previous experiments have always shown them to lack penetrative power and that, although certain bacilli fully exposed on the surface to the rays could be killed, even the slightest interference or protection is sufficient to prevent any action. The Committee is unaware of any previous experiments on anthrax spores as found in wool. The investigators, however, stated that they had discovered a means of so concentrating the rays as to obtain penetrative power and they were extremely confident that by their method any wool, whatever its bulk, would be completely sterilised on exposure to the action of the concentrated rays.

Accordingly arrangements were made for their apparatus to be fixed up and for bales of wool containing known infected test material to be submitted to the action of the rays. The test was carried out on March 15 in the presence of the two investigators and their assistants, who manipulated the apparatus, Dr. Eastwood, Dr. Eurich, and the members of the Departmental Committee on Anthrax. The apparatus set up by the investigators consisted of two Cooper-Hewett mercury-vapour lamps and an X-ray apparatus and was placed in such a position as to "focus" the rays on the two bales of wool containing the infected test material, which were placed behind another row of bales interposed between the test bales and the source of the rays. They were exposed to the action of the rays for ten minutes. After the experiment the bales were removed to the Government Wool-Disinfecting Station, the infected blood clots removed in the presence of the investigators, Dr. Eurich and the members of the Departmental Committee on Anthrax, and placed in sterile receptacles. One blood clot from each bale was handed to Dr. Eurich, who took it away with him, and one blood clot from each bale was sent to Dr. Eastwood for examination. The reports of Dr. Eurich and Dr. Eastwood are as follows :—

March 20, 1922

Report on infected test material (after test)

Blood clot 2 and blood clot 4. From bales exposed to ultra-violet rays. Anthrax bacilli cultivated after 18 hours' incubation.

Anthrax bacilli were cultivated rapidly and with ease from all these clots. There was also an abundant growth of other bacilli. The vegetative functions of the anthrax spores have, therefore, not been influenced by the exposure to ultra-violet rays and sterilisation has failed. Whether their toxic properties have been affected is a question which I am not in a position to answer.—(Sd.) F. W. Eurich.

March 20, 1922

Report on test material (after test)

In connexion with an investigation at Liverpool on March 15, 1922, as to the action of combined ultra-violet and X-rays upon anthrax spores, I have made bacteriological examination of two samples (Nos. 1 and 5). No. 1 was in the centre of a press-packed bale of wool, and No. 5 was in the centre of a hand-packed "square" of wool. Both bales were exposed to the treatment.

I have found that there is not the slightest indication of disinfection. Cultures from each sample yielded numerous anthrax colonies, together with an extremely abundant crop of other bacteria. The cultures produced fatal and typical anthrax in guinea-pigs in two days. —(Sd.) Arthur Eastwood.

NOTES FROM HEATHFIELD—II

By the Rector, Rev. B. V. WHITE, M.A.

Dear Mr. Editor,—A stagnant pond in the lower part of my parish has furnished me and the members of my household with a number of interesting problems. It is foul and slimy and has an accumulation of dead leaves, sawdust and other vegetable matter in a high state of decomposition. We have derived some pleasure from viewing portions of the green slime under the microscope, but the bubbles of gas which arise from the decaying mass at the bottom of the pond, especially when it is stirred with a stick, will form the subject of a few observations.

These bubbles may easily be collected in a glass jam pot filled with water and held upside down with the open end of the jar just under the surface of the water. Unless my memory is at fault, there is a fresco in Manchester showing the great John Dalton engaged in collecting such bubbles in the manner I have described. The gas is largely composed of marsh gas or methane, a compound of carbon and hydrogen with the formula CH_4. What other compounds are contained in the bubbles I do not know, and I shall be grateful to any of your readers who will point out to me some exact analysis of any such gases. It is by no means easy for me to follow out in my mind exactly how the gas is produced. If I am asked, I explain that it is made by some putrefactive decomposition of decaying vegetable matter, probably assisted by bacterial action. This usually suffices for my children or my parishioners, but it has no merit except its sonorous and imposing verbiage. How did the plant obtain its carbon and its hydrogen, and how is the marsh gas made and permitted to escape ? These are the questions which I put to myself.

It has been known for a century that living plants absorb from the air a certain amount of carbonic acid or CO_2 ; this they absorb through their leaves ; they also absorb through their roots small quantities of water and compounds of nitrogen. Water is a compound of hydrogen and oxygen H_2O, and the plant has the power of assisting the carbonic acid and the water to combine to make formaldehyde. From the formaldehyde the plants make cane sugar, and plants also contain grape and fruit sugar which my chemical books term glucose and fructose ; nobody seems to know which of these sugars is the first to be formed. Professor Baly of Liverpool has in his own rooms made from carbonic acid and water—not by the help of plants, but in glass bottles and flasks kept in bright sunlight—formaldehyde and a syrup which may be a sugar. This syrup may quite possibly be formose, a name used to describe some sugary mixture whose composition is not known. In any case Professor Baly considers his syrup to be akin to formose. This discovery, a quite recent one in practice though old in theory, has given us a greater insight into the ways in which plants perform their chemical operations than perhaps any other. The Rector of the adjoining parish of Burnsall, to whom I recently explained this, sent me a few days ago some Latin hexameters on this matter, of which I will only quote a small portion :—

> " *tu, Baly, lentus in umbra*
> *Formosam resonare doces aldehydamque*
> *silvas* "—

which means, Thou, Baly, in the leafy shade, teachest the woods to resound with " formose " and " aldehyde." This is a pretty conceit, and the whole poem is full of such.

And other experiments made at Liverpool prove the preparation of various alkaloids by somewhat similar methods, using ammonia and carbonic acid. Some of my friends, who are more sceptical than I am myself, tell me that, as the learned Mr. Stas once showed, and as Mr. Ost and another confirmed later, it is very difficult to free ammonia from alkaloids and other organic bases, and that this fact may account for some of the bodies made at Liverpool; but ever since I was a student at Cambridge, now some years ago, I have been accustomed to accept, without criticism, facts announced at the Royal Institution or the Royal Society.

I am never quite clear whether the plant makes the chemicals or whether the chemicals make the plant. Perhaps Sir William Pope, who I am glad to notice is a contributor to your columns, will explain this for our benefit. As a Professor of Chemistry he will be more familiar with these matters than I am; or, could you, Sir, persuade Professor Baly to write a lucid explanation of the point. So far as I can understand the matter the plant is continually absorbing its chemical reagents from the air and the soil, provided the light is there and the weather not too cold; and these will, under suitable conditions of light and heat, act together and make aldehydes and sugars, and from these cellulose and ligno-celluloses, which are the principal constituents of wood and cotton and some other substances. This means a growth of the substance of the plant, which must steadily increase its stature and its bulk so long as the conditions are favourable. So to some extent it is true that chemicals make the plant; yet, on the other hand, the plant has certain qualities which it has inherited from its ancestors and cannot be altered.

The seed of the mignonette has in it some substance which fixes the sort of plant which will be made, the shape of its leaves, the colour of its flower, and the peculiar scent which belongs to it. This quality is well portrayed in the poem, " Progress of Man," written a hundred and twenty years ago by Canning or Frere, and it is as true to-day as it was then. Some plants have the inherited power of making very peculiar chemical compounds, and the nature of these depends only on the plant itself; the quantity of the substance manufactured will very likely depend on the warmth, the light, the richness of the soil and the amount of rain. But the foxglove will make a complicated substance called digitalin, the potato will make starch, and the artichoke will make inulin, and unless it is the nature of the plant to do so, you cannot in any way compel the chemicals to unite and form these compounds, no matter how you alter the temperature and other conditions, which is indeed a curious instance of the mysteries of Nature.

Most plants contain cellulose and derivatives of this substance; it seems to be the decomposition of the cellulose and the ligno-celluloses which liberates the marsh gas, especially the ligno-celluloses. These each contain a CH_3 group, and it is quite possible that when they break up the CH_3 groups unite with the extra atoms of hydrogen and so make the CH_4 which we can collect in our jam jars.

Your pages have been much occupied of late by a controversy concerning the best method of burning fuel so as to secure economy and the prevention of smoke. The late Dr. Benjamin Franklin, an American philosopher, who was elected into the Royal Society so long ago as 1756, paid close attention to this question, and, in the second volume of his collected works, devoted nearly one hundred pages to describing and depicting many elegant and efficient devices for burning pitcoal in such manner as to combine the greatest heating effect with the least smoke production. A comparison of Dr. Franklin's disquisition with the discussion in your columns suggests that matters are much as he left them one hundred and fifty years ago. When your disputants peruse the work of this long-departed philosopher they will note the following injunction :—" And, indeed, all our knowledge is so imperfect, and we are from a thousand causes so perpetually subject to mistake and error, that positiveness can scarce ever become even the most knowing; and modesty in advancing any opinion, however plain and true we may suppose it, is always decent, and generally more likely to secure assent. Pope's rule, ' To speak, though sure, with seeming diffidence,' is therefore a good one."

Festina lente is a good rule, but in this instance the precept has been used to excess.

If you think my letter worthy the notice of your respectable Society you are at liberty to lay it before them; they will consider it, I hope, as it was intended, as an humble attempt to promote a more minute inquiry into these intricate chemical processes.

[Our valued contributor seems to refer to Stas, Œuvres complètes **1**, 375 and Ost and Bannow, Journ. f. prakt. Chemie, 1883 [2], **28**. 271.—Editor.]

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

The Advertisements in this Journal

were the subject of a conversation which was taking place among a number of members of the Society when I joined them the other evening. The manner in which they were displayed was favourably mentioned, but the number of pages which they occupied was the source of much outspoken comment. It has often puzzled me why advertisers advertise, and if they must, and I am told they must, why they advertise in the way they do. I am aware that of recent years a very clever and select body of men have arisen, who call themselves "business builders" or some such name as that, and are prepared to supply any sort of scheme required to advertise a particular business. These must be exceptional people, but there is in every business one person who has the spending of so much money for the purpose of advertising the business.

How are Advertisements Allocated ?

Presumably a certain sum of money is decided upon which is the limit of the amount to be spent in a particular year. On what principle is this money spent ? I wish someone would tell me. The theory of the thing is that the advertiser has something to say about his goods and wants to say it at the cheapest possible rates to the largest number of prospective buyers. So far, so good ; the size of a paper's circulation is something, but it is not all. It is surely the number of prospective buyers into whose hands the paper goes which is the measure of a paper's usefulness as an advertising medium. In other words, the paper must go into the counting-house and the secretary's offices if it is to get to prospective buyers. The paper which has the news and the kind of articles which the occupants of those offices read is the paper which ought to get the advertisements.

It is extraordinary

what a meeting-place the Chemical Section of the British Industries Fair is becoming annually. On the opening day, when the King and Queen were being conducted round the Chemical Hall, I noticed that most of the directors of the firms represented by exhibits were in attendance, and prior to the Royal visit were engaged in friendly conversation. What a change ! Five years ago some of these gentlemen hardly knew each other—to speak to. Later in the week I observed Colonel Jos. I. McMullen of the U.S. Army, who is over here from America on important business, filling in time between two appointments by examining the exhibits, and not missing much. Early this week Mr. Percy Ashley, the Assistant Secretary to the Board of Trade, who is responsible for the Industries and Manufactures Branch, was also there. Perhaps the schoolboys were the most interesting visitors to watch. They seemed instinctively to pick out the exhibits where the most long-suffering attendants were on duty, and they acquired not only a wealth of information verbally, but their acquisition of the printed word was even more voracious. Some science masters are in for a bad time !

Broadcasting

is very much in the public eye at the moment. Critics complain that it is a base use of the fruits of pure science—an argument which seems strangely familiar—and that the transmissions are too short or too high-class or not high-class enough. Some detect a reactionary tendency in a sermon ; others declare that the British Broadcasting Company has been "got at" by ecclesiastics and forced to begin not earlier than 8.30 p.m. on Sundays. Speculation is rife as to the effect which this "new art of broadcasting" will have on those who spend much of their time listening to it. This last query is one which may well be of some interest to scientists. To those who would look into this I suggest a line of inquiry. It is well to remember that quite half the amateur sets in the country are run on the technical, if not on the financial side, by boys—principally those with some interest in things scientific—many of whom will make some branch of science their profession when they grow up. There is some value as a scientific training to be found in the manipulation and repairs (no light task) of wireless apparatus, and this must be balanced against the tale of home-work neglected and interest diverted from ordinary school-work. It is not broadcasting, however, which should cause us the more immediate concern in this field. As has been pointed out over and over again, we are deplorably short of high-power commercial stations : it is a defect which must be remedied with the least possible delay. The developments of wireless will no doubt be enormous, and I was amused to read in the newspaper this morning, in Sir J. J. Thomson's speech at the opening of the General Electric Company's new laboratory, how Lord Kelvin wished to restrict the capital of the first wireless company to £100,000, because that seemed the utmost amount of capital that could find useful employment in wireless telegraphy. If it is true that a process will always take three or four times as long as is expected, it is undoubted that it will always cost five or six times as much as the pioneers estimate. Even while the first plant is being erected, fresh possibilities and improvements become manifest. One should never commit one's prophecies to paper or disclose them to a man who keeps a diary.

FORTHCOMING EVENTS

Mar. 3. UNIVERSITY OF LIVERPOOL, Adelphi Hotel, Liverpool, at 7.30 p.m. Dinner in connexion with the opening of the new Chemical Laboratories.

Mar. 3. THE ROYAL INSTITUTION OF GREAT BRITAIN, 21, Albemarle Street, W. 1, at 3 p.m. "Atomic Projectiles," by Sir E. Rutherford.

Mar. 5. INSTITUTION OF RUBBER INDUSTRY, Engineers' Club, Coventry Street, Piccadilly, W. 1. "Telegraph Cable Manufacture, Rubber and Gutta Percha," by H. Savage.

Mar. 5. SOCIETY OF CHEMICAL INDUSTRY, *London Section*, Engineers' Club, 39, Coventry Street, W. 1, at 8 p.m. "Industrial Poisoning and the Works Chemist," by Dr. T. M. Legge.

Mar. 6. SOCIETY OF CHEMICAL INDUSTRY, *Edinburgh and East of Scotland Section*, Hall of the Pharmaceutical Society, 36, York Place, Edinburgh, at 7.30 p.m. Annual Meeting.

Mar. 6. SOCIETY OF CHEMICAL INDUSTRY, *Birmingham and Midland Section*, the University Buildings, Edmund Street, Birmingham, at 7 p.m. "The Influence of Protective Colloids upon the Velocities of Chemical Reactions," by J. Newton Friend.

Mar. 6. ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, 35, Russell Square, W.C. 1, at 7 p.m. "An Electric Indicator for Washing-troughs," by K. C. D. Hickman.

Mar. 7. THE INSTITUTION OF SANITARY ENGINEERS, Caxton Hall, Westminster, S.W. 1, at 7.30 p.m. "The Mechanics of the Activated Sludge Process," by J. A. Coombs.

Mar. 7. THE INSTITUTE OF METALS, Institution of Mechanical Engineers, Storey's Gate, S.W. 1, at 10 a.m. to 5 p.m. Annual General Meeting. Also on March 8.

Mar. 7. THE INSTITUTE OF CHEMISTRY, *Leeds Area Section*, The Queen's Hotel, Leeds, at 7 p.m. "Chemical Jurisprudence," by Capt. J. A. Foster.

Mar. 8. SOCIETY OF CHEMICAL INDUSTRY, *Ottawa Section*, University Club, Elgin Street, Ottawa, at 8 p.m. "Chemistry in the Canadian Civil Service," by Government Chemists.

Mar. 8. SOCIETY OF DYERS AND COLOURISTS, *London Section*, Dyers' Hall, Dowgate Hill, E.C., at 7 p.m. "The Valuation of Dyestuffs by Titration Methods," by R. B. Brown and H. Jordan.

Mar. 8. INSTITUTE OF CHEMISTRY, *Liverpool and North-Western Counties' Section*, Chemistry Lecture Theatre, Liverpool University, at 7.30 p.m. "Chemical Warfare," by Major V. Lefebure, O.B.E.

Mar. 9. INSTITUTE OF METALS, *Sheffield Local Section*, Mappin Hall, The University, St. George's Square, Sheffield, at 7.30 p.m. "Further Notes on Britannia Metal," by Capt. F. Orme.

NEWS FROM THE SECTIONS

MONTREAL SECTION

The January meeting was held at the Queen's Hotel, and was preceded by dinner. Dr. MacLean, the Chairman, presided, and was supported by Dr. R. F. Ruttan. The lecturer of the evening was Dr. H. E. Howe, editor of the *Journal of Industrial and Engineering Chemistry*, New York.

Chemistry as the maker and breaker of nations was his theme, and Dr. Howe emphasized the need of enlightening the general public, and particularly business men, on the great debt owed to the chemist, and, incidentally, of impressing upon the chemist himself the vital importance of his profession, and the absolute dependence of the world on his knowledge. The duty consequently devolved on the chemist of asserting himself and forcing recognition of his profession as one of paramount value to the world. Dr. Howe showed the power which chemistry has wielded in several notable instances, and its close relation to finance and prosperity. Chemistry developed the purple hue used by the merchants of Tyre and Carthage, from the fluid secreted in the tiny shell of a Mediterranean mollusc, and this lent largely to the riches of the two ancient cities. By the use of the deadly Greek fire, chemistry decreed that the siege of Constantinople should come to naught. Chemistry discovered the art of making weapons from metal, and thus moulded the destinies of early warring mankind. In later times the same science gave birth to margarine at the siege of Paris by the Germans in 1870, and during the Napoleonic Wars, when the continent was blockaded by the British Fleet, the art of deriving sugar from beets was utilised by the French to circumvent the efforts of the British. Since that time both France and Germany have steadily increased the amount of their beet-sugar production, and now, instead of being an importer of sugar, France, only a few years ago, exported about 250,000 tons of beet sugar annually. Without TNT the Germans would have had far more difficulty in blowing up the foundations of the Belgian fortresses, and without chemistry to fight disease, the Panama Canal would never have been built. Dr. Howe referred also to the discovery of gunpowder, which set the nations hunting for nitric acid, and saltpetre from which the acid is obtained. By chemistry the West has been able to break the camphor monopoly, held, not long ago, by the Japanese. With its large deposits of sulphur, used for making sulphuric acid, the United States has been able to obtain its share of international safety. Chemistry is the key to international relations, declared Dr. Howe, for it sometimes seems that the nations are all striving for power and the right to exploit conquered peoples.

In the future the ascendancy will lie not with that nation which has the most natural resources, but with the nation which best knows how to use its resources. The chemistry of the future will form the most fearful, humane and efficient weapon yet wielded on this earth. It will put a premium on intelligence, and it will be a leveller of nations, for a small nation with a superior knowledge of the war-time operations of chemistry will be able to outdistance her larger but slower neighbour. The Germans once built a large part of their hopes for world power on their mastery of the making of dyes. At present Germany is attempting to make liquid fuel from coal, and further, the Germans believe they possess the key to tropical Africa in an antidote which effectively combats sleeping sickness. Germany will not give this secret to other peoples without exacting her price : the restoration of her African colonies. Canada's debt to science is mainly for its development of asbestos, nickel and the manufacture of paper.

Prof. R. F. Ruttan referred to Dr. Howe as the man who had done more than any other to make known to industry the vast importance of research. Prof. J. F. Snell, of Macdonald College, and Messrs. C. F. Bardorf, of the St. Lawrence Sugar Refining Company, and T. H. Wardleworth spoke briefly.

NOTTINGHAM SECTION

At the meeting held on February 21, presided over by Mr. S. F. Burford, F.I.C., a paper by Messrs. A. Brittain, M.Sc., and C. Elliott, B.Sc., on " Plaster of Paris," was read by the former.

In a brief survey of previous work the authors referred to the papers of Davis (this J. **26**, 727) in 1907 and of Keene in 1916, also to one read last November before the Ceramic Society. The order of changes on heating is from the monosymmetric form of the dihydrate (gypsum) to the orthorhombic then to orthorhombic half-hydrate, and to the soluble or one of the insoluble forms of anhydrite. Slides were shown illustrating the aqueous vapour-pressures of different systems at 100° C., and the temperatures of the transitions. According to the authors' experiments the hemihydrate is formed between 109° and 130° C., and anhydrite between 160° and 200° C. It becomes dead burnt at 200° C., but even then will rehydrate if ground sufficiently finely. The design of the closed kettles used in America was then explained. These include settlers in which large quantities of dust carried away with the escaping steam are collected. In the Cummer continuous rotary process, the furnace gases pass through the material, the calcination is completed in three stages and the material is ground after calcination. The two conversion or " boiling " temperatures are at about 120° to 130° and 190° C., with loss of 12 to 16 per cent. and 6 per cent. of water, respectively. In the English open pans stirred by chains, the " boiling " occurs at about 118° C.

The fuel consumption per ton of plaster produced is about 80 lb. of coal in the rotary process, 95 to 200 lb. in the kettle and 400 to 480 lb. in the English open pan. The great inefficiency of the English process is due to excessive surface radiation and poor heat-transmission through the thick iron or tile bottoms. Experiments showed that a thinner plate and the use of producer-gas instead of solid fuel improved the efficiency.

Plaster always contains gypsum even when it also contains much insoluble anhydrite. The presence of the gypsum accelerates the setting, probably by providing nuclei of crystallisation, but decreases the strength, since it does not enter into the crystallisation, but acts like an inert material. A similar effect is produced by overburnt anhydrite. The use of accelerators and the effect of varying the amounts of water were also briefly described.

In the discussion which followed Mr. Pentecost referred to the analogous advantage of fine grinding in the drying of starch, and Mr. J. M. Wilkie expressed satisfaction that the section had at last heard a paper on this typically local industry. Dr. Firth alluded to a German patent in which it was claimed that the theoretical quantity of water gave the hardest set product. Was there a possibility that on long storage the anhydrite might dehydrate gypsum ? Dr. Prideaux wished for information on the chemical changes associated with the first and second setting. In gauging the plaster with water was it usual or advisable to allow for the relative proportions of half-hydrate and anhydrite ? Another speaker asked why commercial plaster sometimes set quickly and then gave again, and the Chairman wished to know whether there were critical temperatures in the setting.

Mr. Brittain, in reply, said that all the other constituents were estimated and the gypsum obtained by difference. When heated above 800° C., anhydrite was again capable of setting, and it gave a basic sulphate above 1000° C. The term "first set" was a misnomer; it merely meant the point at which the plaster became unworkable. Plaster made from the sulphate of lime recovered in the manufacture of phosphoric acid set slowly but gave a hard and dense product.

GLASGOW SECTION

The Ramsay Chemical Dinner was held in the Grosvenor Restaurant on February 23, and was attended by members of the Society of Chemical Industry, the Institute of Chemistry, the Society of Dyers and Colourists, the Glasgow University Alchemists' Club, the Andersonian Chemical Society, and the Ardeer Chemical Club.

Professor G. G. Henderson, F.R.S., presided, and the guests included Sir Thomas Paxton, Bart., Lord Provost of Glasgow, and Lady Paxton; Dr. E. F. Armstrong, F.R.S., President of the Society of Chemical Industry; Mr. C. R. Gibson, President of the Royal Philosophical Society of Glasgow; and Mr. G. A. Mitchell, President of the Glasgow Chamber of Commerce.

Mr. C. R. Gibson, in proposing the toast of "The Joint Chemical Societies," said that the Society of Chemical Industry was the largest chemical society in the country and had local sections throughout the world. They honoured that evening the memory of Sir William Ramsay, a past president of the Society, and they were happy to have in the chair another distinguished past-president and to have with them the ruling president, Dr. E. F. Armstrong.

Of the other societies included in the toast, the Institute of Chemistry was a body which looked after the interests of the profession, and the Society of Dyers and Colourists was devoted to the interests of the dyeing and allied industries. The Students' Societies were represented by the University Alchemists' Club and the Royal Technical College Andersonian Chemical Club. These societies served a very useful purpose and afforded opportunities for the discussion of problems of academic and industrial importance. The Ardeer Chemical Club was composed of members of the research staff of Messrs. Nobel Explosives Works at Ardeer. It was a pleasure to think that this firm realised the importance of chemical research. He welcomed the spirit of co-operation which had brought the societies together, and he suggested that a proposal to form a chemical section of the Royal Philosophical Society of Glasgow would be welcomed by the Council.

The chairman responded to the toast and referred to the formation a few years ago of the Federal Council of Pure and Applied Chemistry, which was intended to be representative of all the chemists in the country. They wished, he said, to impress upon the public that the profession of chemistry was one of the most important, if not the most important, in the country. The future prosperity of the country depended largely on the development of chemistry, and it was very necessary that the people should realise it. The importance of the profession would be realised only by the co-operation of the chemists themselves, and he was glad that a step in this direction had been taken.

Dr. E. F. Armstrong, F.R.S., in proposing the toast of "The City of Glasgow," said that they all had pleasant memories of Glasgow and of the meeting held there last July. The position which Glasgow occupied in the commercial world was second to none. The Lord Provost replied and appealed to chemists to assist the movement for obtaining a purer atmosphere in Glasgow. The air was polluted by burning raw coal and especially by burning it in the domestic fireplace. He thought that chemists could help him and the Corporation to ensure purer air for the citizens. Mr. W. E. Moodie, chairman of the local section, proposed the toast of "The Guests." Mr. G. A. Mitchell, in reply, referred to the appeal made by the Lord Provost for a smokeless fuel and to the fact that chemists had been able to produce a smokeless fuel from raw coal. Attention must now be given to details so that a cheap product might be available.

BIRMINGHAM AND MIDLAND SECTION

Dr. E. B. Maxted presided at the special meeting, held on February 20, in co-operation with the Chemical Society.

Prof. G. T. Morgan and Mr. F. R. Jones read a paper on the "Interaction of Formaldehyde and the Nitro-naphthylamines," in which they pointed out that the seven known nitronaphthylamines have been condensed with formaldehyde under varying conditions:—4-Nitro-α naphthylamine and 2-nitro-α-naphthylamine give dinaphthylmethane bases; 1-nitro-β-naphthylamine furnishes the hydrolysable methylenebis-1-nitro-β-naphthylamine, which exists in two differently coloured modifications; 5-nitro-β-naphthylamine gives rise to two products, a dinaphthylmethane base and a dinaphthacridine; 8-nitro-β-naphthylamine gives methylenebis-8-nitro-β-naphthylamine, which becomes transformed into a dinaphthylmethane base; 5-nitro-α-naphthylamine resembles α-naphthylamine in yielding ill-defined products; whereas 8-nitro-α-naphthylamine furnishes methylenebis-8-nitro-α-naphthylamine and a dinaphthylmethane base which has the noteworthy property of separating in yellowish white tabular crystals containing three molecular proportions of formaldehyde. These results indicate that the nearer the nitro-group is to the amino-radicle in the nitronaphthylamine the more marked is the retarding effect of this nitro-group on the condensation with formaldehyde.

A "Note on the Preparation of β-Naphthol-4-sulphonic Acid," presented by Prof. G. T. Morgan and Eveline Jones, described an attempt to obtain β-naphthol-4-sulphonic acid from the commercially available naphthalene-1-diazo-2-oxide-4-sulphonic acid by boiling this diazo-compound with alcohol, when elimination of the diazo-group occurs, the resulting β-naphthol-sulphonic acid being characterised by means of its azo-derivatives with the diazonium salts of *p*-toluidine, *p*-nitroaniline and β-naphthylamine.

A paper on "Hydrogen Ion Determination," was read by Mr. S. R. Carter. The advantages of reducing all degrees of acidity and alkalinity to one common scale were demonstrated and the basis of Sörensen's hydrogen ion experiment was explained. The constitution of indicators was discussed and their application to the determination of p_H values was illustrated by experiments. The latter portion of the lecture was devoted to the electrometric methods employed for hydrogen ion measurements, and to electrometric titrations; the principles involved were illustrated by potentiometers and electrodes lent by the Cambridge and Paul Instrument Co.

MEETINGS OF OTHER SOCIETIES

BIOCHEMICAL SOCIETY

Dr. Dale presided over the meeting held in the National Institute for Medical Research, Hampstead, on February 12, and the following communications were read:—

(1) "A Comparison of the p_H Determined Electrically with the p_H Calculated from the Carbon Dioxide of Blood in Pathological Conditions": T. R. Parsons and E. P. Poulton. Two methods of calculation were employed:—(1) Warburg's Method (Biochem. J., **16**., 153, 1922); (2) from the carbon dioxide of the plasma, using a relation established by Campbell, Hunt and Poulton (Journ. Path. and Bact., in the press) for the carbon dioxide of the blood and corresponding true plasma, according to the formula $p_H = 6\cdot1 + \log$(combined CO_2)—log (free CO_2). In the latter case the blood must not be anæmic or, with certain reservations, polycythæmic. Neither method should be used if the blood contains excess of fixed acid. Under these circumstances the carbon dioxide in true plasma must be determined directly. Out of 39 observations on various pathological cases (without fixed acid), 82 per cent. (by Warburg) and 79·5 per cent. (Campbell, Hunt and Poulton's method) were not further away than 0·05 p_H from the value actually determined with the hydrogen electrode.

(2) "The Blood in Polycythæmia": J. M. H. Campbell, G. H. Hunt and E. P. Poulton. One case of erythræmia and four cases of congenital heart disease with polycythæmia were investigated. The power of fixing carbon dioxide was much diminished (average, 34 c.c. at 40 mm.); this was not accounted for by the increase of red cells, so that fixed acid must have been present. This was abolished in one case of erythræmia after five days in an oxygen chamber, though the blood picture was not changed. In these cases the arterial carbon-dioxide pressure was normal, so that the arterial p_H was diminished. The percentage oxygen saturation of the blood was diminished in all the cases, but especially in the congenital heart cases (pulmonary stenosis and patent septum), so that there must have been a mixture of the blood from the veins and from the lungs in the arteries. It was also shown that polycythæmia itself leads to faulty æration of the blood in the lungs. Want of oxygen leads to increased ventilation, and in the congenital heart cases the alveolar carbon dioxide is much lower than the arterial carbon-dioxide pressure. Breathing oxygen in these cases does not lead to diminished ventilation, and the explanation is that though the oxygen want is relieved the arterial carbon-dioxide pressure is raised, whilst the fixed acidity remains the same, so that the arterial p_H is diminished. These two factors probably neutralise each other in their effect on the respiratory centre.

(3) "On the Mode of Action of Vitamins": W. Cramer. On withholding the fat-soluble vitamin "A" from the diet of rats an atrophic condition of the intestinal mucous membrane results. This is especially marked in the lower part of the small intestine where the villi are necrosed. The same lesion occurs after exposure to large doses of X-rays and radium. This is, therefore, another instance of the fact that the tissue lesions produced by radiations on the one hand and vitamin deficiencies on the other are essentially similar. The intestinal lesion rapidly disappears under the influence of cod-liver oil. It is specific for vitamin "A" deficiency and does not appear when vitamin "B" is withheld, when a different atrophic intestinal lesion is produced—namely, atrophy of the lymphoid tissue (Peyer's patches). The intestinal lesion produced by vitamin "A" deficiency accounts for most, if not all, the general effects occurring in that condition: cessation of growth, infection, thrombopenia. The intestinal mucous membrane of rats kept since birth on a diet which, though adequate to maintain the animals in apparent good health and enable them to grow and to breed, was restricted in its vitamin content, differs in its appearance from that of rats kept on the same diet supplemented amply with vitamins: in the latter animals the villi are distinctly bigger. The observations confirm the views expressed in previous papers concerning the mode of action of vitamins. These food accessory substances have a drug-like specific stimulating action on certain parts of the digestive tract. These parts are, in fact, dependent for the full development of their functional activity on an abundant supply of these vitamins in the food, and undergo atrophy in the absence of these vitamins. In this respect the vitamins resemble hormones, in the absence of which atrophic changes occur in certain tissues (atrophy of the uterus in the absence of the ovarian hormone, atrophy of the testes in the absence of the pituitary hormone). The generalisation that all cells require vitamins is incorrect and should be abandoned, The same applies to the idea that vitamins contain "growth promoting" factors.

INSTITUTE OF CHEMISTRY

A crowded meeting of the Huddersfield section was held on February 15, in the Technical College, to hear a lecture by Prof. W. L. Bragg on "X-rays and Crystal Structure." The chairman, Dr. H. H. Hodgson, in welcoming the distinguished lecturer, said that no chemist needed an introduction to the work of Prof.

Bragg, but that the chemists of Huddersfield had been looking forward for some time to personal contact with him. Prof. Bragg first described crystal structure and the phenomena of crystallisation, remarking that all true solids were crystals. He then proceeded to the analysis of crystals by X-rays, and compared the results with those obtained by microscopical investigation. Following this came a description of the light which the analysis throws on chemical composition, revealing the beautiful underlying architecture of crystals in its entirety. Particularly does the method afford a means of finding the distances between the atoms in the solid state. A wider aspect of the field was then reviewed, including the nature of chemical combination and the forces of chemical attraction, and an answer was given to the question of why the properties of substances alter so completely when they are combined, *e.g.*, why common salt is so different from its constituents, sodium and chlorine. The cognate problem of the seat of atomic individuality was then considered. In discussing atomic and molecular dimensions, many characteristics were explained from the standpoint of electrostatics, *e.g.*, the problems relating to heats of solution and heats of formation of substances. The final section of the lecture was devoted to the insight which X-ray analysis affords for the study of chemistry. No longer can barriers be erected between chemistry and physics, since recent work by the physicist has broken the existing but always artificial boundary.

ROYAL INSTITUTION

On February 8, Prof. I. M. Heilbron gave a lecture on the "Photo-synthesis of Plant Products," devoted more especially to the synthesis of organic nitrogen compounds. Pictet, he said, believed that alkaloids were formed by the degradation of more complex compounds such as protein or chlorophyll, but Gadamer and Prof. Robinson considered that they were actually primary products of assimilation. In general, it could be assumed that, except in plants living in association with nitrogen-fixing bacteria, nitrogen entered the plant through the roots in the form of some soluble nitrogen compound. The work of Moore and his collaborators, however, seemed to show that in the absence of sources of nitrogen other than atmospheric, unicellular algæ could fix nitrogen and form proteins in presence of an abundance of carbon dioxide.

The key to the formation of alkaloids was to be found in activated formaldehyde. Prof. E. C. C. Baly and himself had found that activated formaldehyde—*i.e.*, formaldehyde produced by photosynthetic action, reacted with nitrogen to form formhydroxamic acid, which at once combined with more activated formaldehyde, producing a variety of complex nitrogenous compounds similar to those found in the living leaf. It was found that if excess of nitrite were used, formhydroxamic acids and nitrogen compounds alone were produced, but in the presence of excess of formaldehyde, sugars were produced in addition to nitrogen compounds. Activated formaldehyde could condense with formhydroxamic acid in three ways, to form either amino-acids, alkaloids or glyoxalines. On replacing the nitrite by ammonia it was found that whether one started from carbon dioxide and ammonia or from activated formaldehyde, on exposure to the light the same compounds were attained. Evidence had been obtained of the production of methylamine, pyridine, piperidine, and other substances.

INSTITUTION OF RUBBER INDUSTRY

A paper on "Technology in the Rubber Industry" was read by Mr. W. A. Williams at the meeting held on February 5.

Mr. Williams said that much that is possible in the modern rubber factory is due to the labour of chemists. But for the work of the chemist and the metallurgist we should have been still struggling along with toy machines such as those used by Hancock and Goodyear, possibly manufacturing nothing better than waterproof coats and pencil erasers. Although the rubber industry has been possible through the agency of the chemist indirectly, it is only within recent years that the chemist has come in direct touch with rubber manufacture. His inclusion in the factory organisation has synchronised with the rapid development of the industry during late years, and the problems that have presented themselves could not have been handled by the strictly-practical man. The success of a technical and scientific department in factory organisation depends solely on the staff. What is wanted is not so much the specialist as a man who has had a broad scientific training, with chemistry as his special subject; the factory and laboratory training that follows after his engagement will make him an efficient works chemist. The organisation I will outline is one to meet the requirements of a large plant, but has the advantage that it can be adapted to smaller factories.

The laboratory sections and the full organisation are as follows: (*a*) chemical research laboratory, (*b*) physical research laboratory, (*c*) chemical routine laboratory, (*d*) physical routine laboratory, (*e*) mixings control laboratory, (*f*) experimental laboratory, (*g*) power, fuel and boilers laboratory, (*h*) contracts and specifications laboratory, (*i*) specifications and supplies link, (*j*) work-planning department.

It is somewhat difficult to foretell the character of the investigations that may be asked from the chemical research laboratory, as the work of a rubber factory is very varied. As examples of the work to be carried out, I would instance investigation to obtain a clearer understanding of the nature of crude rubber to ensure the supply of a uniform raw material;

to evolve suitable analytical methods for use by the laboratory sections which control manufacture. Research work on the production of accelerators has become very important of late, and investigations on reclaiming should not be lost sight of. In the physical research laboratory problems will be handled comprising physical work on new methods and new manufactures, together with the investigation of improvements on existing manufactures. Example of the class of work undertaken by this section are the photo-micrographic examination of pigments correlated with their stress-strain diagrams, and the application of accelerators as distinct from their production on a manufacturing scale. Through the chemical routine laboratory passes all the chemical routine work of the factory, such as the checking of deliveries of supplies against standard specifications, and of samples of the factory products. This section carries out any routine chemical testing required by the other laboratory sections. The physical routine laboratory has duties similar to those of the chemical routine laboratory in that it deals with the check testing of supplies and of the manufacture at various stages of production up to completion and draws the immediate attention of the department concerned when the tests do not show adherence to the manufacturing specification.

The mixings control laboratory is concerned with the adjustment of manufacturing difficulties arising from mixing and vulcanisation; the supply of new mixings to the factory as may be required, and the control of the factory drug departments. In the experimental laboratory work is carried on for the improvement of current manufacture both in quality and build, and the initiation of the manufacture of new articles. The power, fuel and boilers laboratory deals with questions of boiler control, inefficient firing, water softening and lubrication, and keeps a close check on the calorific value of the fuel purchased. The duties of the contracts and specification's laboratory are to assess qualities against specifications which are furnished by prospective customers, the detailed work being carried out either by the chemical or physical routine laboratory. The specifications and supplies link drafts working specifications for all standard manufactures and new productions for the factory, giving necessary details of qualities, weights and measurements, but not interfering with details of the processes. In the work-planning department, consideration is given to all labour and manufacturing operations to economise labour, reduce fatigue and cut down waste.

It should be the duty of the chemist in charge of his respective section to see that the work of the section is properly recorded, and reports on all the work should be filed, and copies sent daily to the works manager, who can then adjust faults which, if not attended to, may later lead to complaint. The reports of the respective departments are in turn circulated through the whole of the laboratory sections, as it is essential that the departments must not work on a water-tight plan. Each section must be conversant with the work of the other section, for the problems are interdependent and valuable suggestions and assistance are obtained by bringing to bear on the subject the different points of views of all the sections concerned.

An outline has thus been given of an organisation for scientific and technical control which, in its complete form, would meet the requirements of a large concern, but which can be started on a small scale and built up as the factory grows. Naturally, large organisations were the first to appreciate the advantages of scientific control and research, and it is due to that appreciation that they have improved their factory processes and costs of production at the expense of their smaller rivals. Such an organisation, however, can only touch the fringe of the subject of research and problems await the detached investigator that are of interest to the whole industry and these can best be carried out by pooling the costs and results of scientific research, such as is done by the Research Association of the British Rubber and Tyre Manufacturers' Association. The success of the industry depends upon its ability to command the application of improvements and reduced costs, which in these days can be achieved by no rule-of-thumb methods. We must, therefore, continue to advance, or be surpassed by other nations which are using science in the struggle for world trade.

THE ROYAL SOCIETY

The Council of the Royal Society, at the meeting held last week, decided to recommend for election into the Society the following from the list of candidates :—

Edgar D. Adrian, M.A., M.D., Lecturer in Physiology, University of Cambridge.

W. L. Balls, M.A., Sc.D. Work on cotton.

Professor Archibald Barr, D.Sc., LL.D. Professor of Civil Engineering at Leeds, 1884–1889, and Glasgow, 1889–1913, well known for his work on range-finders.

Prof. C. H. Desch, D.Sc., Ph.D. Prof. of Metallurgy, Sheffield, who has written on Planimetric Analysis of Alloys, Composition of Eutetics, Solidification of Metals, Hardness of Solid Solutions, Absorption Spectra, Cement and other topics.

Prof. E. Fawcett. Prof. of Anatomy, University of Bristol.

Prof. F. Horton, Sc.D. Prof. of Physics, Royal Holloway College, who has published work on the Discharge of Negative Electricity from Hot Calcium, Ionisation Potentials for Electrons in Helium, etc.

R. T. Leiper, M.D., D.Sc. A distinguished parasitologist.

Prof. J. W. McBain, M.A., D.Sc. Prof. of Physical Chemistry, Bristol, who has investigated the properties of silver-tin alloys, the nature of soap solutions and developed a theory of colloidal electrolytes.

Prof. J. J. Rickard MacLeod. Prof. of Physiology, Toronto University.

G. A. K. Marshall, D.Sc. Director of the Imperial Bureau of Entomology.

Sir Douglas Mawson, D.Sc. Geologist and explorer.

W. H. Mills, M.A., Sc.D. Lecturer in Organic Chemistry, Cambridge, who has worked at optically active oximes, the constitutions of the isocyanines and carbocyanines, etc.

J. S. Plaskett, B.A., D.Sc. Astronomer, Dominion Observatory, Ottawa, 1905–1917.

Prof. H. R. Procter, D.Sc., Emeritus Prof. of Applied Chemistry (Leather) in the University of Leeds, the pioneer in the application of science to the leather industry; has also written on colloid chemistry and other scientific subjects.

Prof. W. Wilson, Ph.D., D.Sc. Prof. of Physics in the University of London; author of papers on the Photo-electric Emission from the Alloy of Sodium and Potassium, and on other topics.

THE NATIONAL MILK CONFERENCE

BY G. CECIL JONES

The report of the proceedings of the National Milk Conference held at the Guildhall, London, in November last, has at last been issued. It is a well-printed volume of 220 pages, and is obtainable from the Conference Secretary, 3, Bedford Square, W.C. 1, price 3s., post free. The papers, twelve in number, are printed in full, and with a few exceptions the contribution to the discussions are reported *verbatim*. This makes a big book, and there is perhaps some danger that its size may scare off some who should read it. They may accept the writer's assurance that the report is extremely easy reading, and that this form of publication was the only safe one, failing a very strong editor or editorial committee. Some editing there has been, but of a kind which makes one glad there was no more.

For the sake of the milk industry it is to be hoped that many chemists will peruse the pages of this report. At every session problems were stated, the solution of which must depend largely on the work of chemists. At the opening session Prof. H. E. Armstrong gave offence to some by saying: "We know nothing of the composition of milk," but it was the right note, and by sounding it and its harmonics at each succeeding session he sent many away convinced that the milk industry has much to learn. The immensity of that service can be realised fully only by those in close touch with the industry and with the officials in Whitehall, who are so satisfied with the present state of our knowledge that they have recently tried to stereotype questionable dairy practice. The papers read at the Conference themselves supported Prof. Armstrong's statement that the industry had everything to learn. The opening paper on "Dairy Breeds of Cattle in Relation to Cost of Production" ended with the statement: "On the cost of milk production according to breed, no reliable data exist." The second paper on "Feeding in Relation to Cost of Production" raised a much more difficult problem but, needless to say, did not solve it. Both papers were valuable for the information they conveyed, but doubly valuable for compelling attention to gaps in our knowledge.

There were papers of a more didactic type, but these were less convincing. For example, there was one on "Pasteurisation," by Dr. Charles North, of New York. It is a good enough statement of one point of view, that which sees the advantages of pasteurisation far outweighing its disadvantages. It was only by accident that the contrary view found exponents at the Conference, and it is surprising that the organisers of the Conference did not seek for someone of this school to open the discussion. The subject has been dealt with recently in these columns by Prof. Armstrong and need not be laboured here, but it may be pointed out: (1) That in addition to its known disadvantages there are reasonable grounds for fearing that it may have disadvantages not yet recognised, and (2) that the Conference was held at a time when the Ministry of Health was known to be framing regulations as to the pasteurisation of milk. Another disappointing paper was that of Dr. Robert Hutchinson. Those of us to whom the first edition of his "Food and Dietetics" was useful expected great things. It is true that book was published in the Dark Ages, when we knew next to nothing of the constitution of proteins, and nothing at all of advitants, but recent work was as accessible to Dr. Hutchinson as to the rest of us, and we expected a masterly survey. We did not get it. Instead we were told that the temperature of pasteurisation was not high enough seriously to affect the anti-scorbutic advitant, and that infantile scurvy after all was a very rare disease. Having no medical qualification, the present writer must leave it at that.

The Editor asked for a short article, not an abstract, so it is unnecessary to give the titles of all the papers. The chief problems of the milk industry are two: (1) to produce milk as economically as possible, and (2) to exclude dirt from it as far as possible from the time of milking until it reaches the consumer. In the solution of these and cognate problems it needs the help of chemists—whole chemists. It is not yet in the mood to pay them, but it must be educated or forced to do so. If trying to carry on without them hurt only the producer and distributor of milk, they might be left to sink, but the economic production of wholesome milk is a problem of national importance.

CORRESPONDENCE

PROFESSOR ARMSTRONG AND WOOL DISINFECTION

Sir,—I am directed by the Secretary of State to say that his attention has been drawn to the article by Professor Armstrong in your issue of February 2, headed "Legislative and Departmental Interference with Industry and the Common Weal," in which Professor Armstrong refers to the proposal for an International Convention for the disinfection of anthrax-infected wool and hair which was submitted to the International Labour Conference at Geneva in 1921. Professor Armstrong's observations on this subject contain several inaccurate and misleading statements, one of which Mr. Bridgeman thinks it important to correct, namely, the statement that "No attempt had been made in advance (*i.e.*, by the British Government) to consult with the representatives of India or the Dominions." This allegation is unfounded. In 1918, after the Home Office Departmental Committee on Anthrax had reported, steps were at once taken officially by the British Government to ascertain the views of the Governments of those parts of the British Empire which appeared to be affected by the proposals, namely, India, South Africa, and Egypt; and in the case of India, which was peculiarly concerned, the various aspects of the question were the subject of full discussion and consultation between the British and Indian Governments.

No similar action was taken in regard to Australia, but this was not because Australia was overlooked, but because the scheme of disinfection recommended by the Departmental Committee and adopted by the British Government, was strictly limited to dangerous materials and excluded wools from countries like Australia, where effective precautions are taken to prevent infection. The British proposals therefore did not affect Australia.—I am, Sir, etc.,

John Anderson

The Home Office, Whitehall
Feb. 20, 1923

Sir,—I can only feel honoured that the Secretary of State deigns to notice my article; but if my "several inaccurate and misleading statements" be of the order of that upon which he comments, they are not serious.

What may or may not have been ascertained in 1918 has little bearing upon what was done in 1921. So much had been done in the interval. The Home Office went into action, at Geneva, either knowing (from inquiries made in 1918) that Indian and other representatives would be opposed to their proposal; or without having ascertained what their attitude *at the Conference* would be. My suggestion is that there should always be consultation between the several units of our Empire before any attempt be made to secure compulsion through the agency of the Geneva machinery; to use Geneva as a lever to make India or any other unit do what the home Government cannot bring about within our own circle by ordinary diplomacy is a very dangerous policy for us to adopt. The occasion was not one for compulsion but for consultation. In the more serious case of White Lead, the English Government knew that Australia, at least, was bitterly opposed to the course taken. To me it seems that the League of Nations is reduced to a farce by such proceeding; if so used, it must increase, not diminish, friction.—I am, Sir, etc.,

Henry E. Armstrong

Lewisham
February 26, 1923

"ROTARY DISPERSION"

Sir,—May I be permitted to correct an error which appears on p. 181 of to-day's issue of Chemistry and Industry? In the papers communicated on February 15 to the Chemical Society, by Dr. R. H. Pickard and myself, the suggestion is made that the complex rotatory dispersion of the organic compounds examined in the course of investigations being carried out in these and other laboratories is due to "dynamic" isomerism—not "geometrical" isomerism. The suggestion is, of course, by no no means new. It was originally put forward, I think, about ten years ago by Prof. Lowry, but it is certainly proving a fruitful working hypothesis.

May I, in conclusion, plead for the general adoption of the term "rotatory," as applied to optical activity, rather than the less euphonious term "rotary," which, in addition, already possesses a well-understood mechanical significance?—I am, Sir, etc.,

Harold Hunter

Chemical Department,
Battersea Polytechnic
February 23, 1923

"ORGANIC" CHEMISTRY

Sir,—It is to be hoped that I am not the only original member of the Society of Chemical Industry equal to a little laughter at times. Sir William Pope is mistaken in supposing that I protest against the "intrusion of such novelties as phase-rules, ions, etc." When there are so many new arrivals with an unfamiliar accent, it surely is not an act of discourtesy for one to step aside and watch. We have seen many come, stay, and prove useful and boon companions when we have got to know them better, but there are others, although exciting our wonder and admiration, who, by persistent intrusion many bring us disquietude, and sometimes hindrance, to our daily work. There is still some work even for empirics, so the suggestion of the lethal chamber is, perhaps, a little premature. What I do protest is, that we have for many years been guilty of using a misleading word—Organic Chemistry. As Sir William says: "Truly, there is but one chemistry"; and it is, undoubtedly, the persistent use of a false term that has caused the present trouble. Chemists are generally agreed that "Organic Chemistry" simply means an extended study of carbon compounds, but the trouble starts when they have to define the exact place where the extension begins, for this certainly can never be done. It is unfortunate that they have not had a word implying this meaning. "Carbology," for instance, although a hybrid, might well have been used; and, again, I see no reason why "Carbonic matter" should not replace the often misused term, "Organic matter," reserving the latter, if used at all, for animal or vegetable organisms or their combustible debris and products of decomposition.—

I am, Sir, etc., JOSEPH BARNES

Arnside, Westmorland
February 19, 1923

SPINACENE

SIR,—May I call your attention to a slight inaccuracy in your account of the paper on "Spinacene," which I communicated last week to the Chemical Society. The work which I published in 1918 was certainly added to, but was not "amended" since—as I pointed out in my earlier paper—all the numbers obtained for Spinacene and its compounds were in much better agreement with the formula $C_{29}H_{48}$ than with the formula $C_{30}H_{50}$. In my recent paper I merely explained that the only compound about which there had been any uncertainty—namely, the dodecabromide—had, as a result of further purification, come into line with the other compounds. To say that I "now consider" Spinacene to be a hydrocarbon, $C_{29}H_{48}$, with six ethenoid linkings is not exactly correct, as I knew and stated that to be its correct description in 1918. What I have since done, among other things, is to work out its probable constitution.—I am, Sir, etc.,

PRICES OF WOOD DISTILLATION PRODUCTS

SIR,—We should like to offer you our thanks for the very excellent Market Report on Wood Distillation Products that you are now publishing.

We may say that we consider the prices quoted are most accurate, with the exception of Wood Creosote at 2s. 6d. (two shillings and sixpence) per gallon. Either we are underrating our product or we are in the wrong market. As we believe we have the largest output of Wood Creosote in this country, we should esteem it a favour if you could give us any indication as to the potential buyers at 2s. 6d. per gallon for this material, or inform us on what basis this quotation is given in the *Journal*.—I am, Sir, etc.,

Per pro SHIRLEY ALDRED AND CO., LTD.

PRICE OF GERMAN PERIODICALS

SIR,—In case you may deem it worthy of comment I send herewith a circular received last night from a well-known Liepzig firm. Their prices make one breathless! Our German *confrères* not only appear to think that English chemists can afford to pay fancy fees for the privilege of belonging to German societies, but that they are also so overburdened with superfluous wealth that they are likely customers for publications priced at figures "beyond the dreams of avarice."—I am, Sir, etc.,

GEORGE R. TWEEDIE

Southfields, S.W. 18
February 13, 1923

[From the very interesting circular sent by our correspondent we extract a few outstanding examples. The circular is issued by the Buchhandlung Gustav Fock of Leipzig. Further comment is needless :—

(1) Berichte der deutschen Chemischen Gesellschaft. Jahrgang 1-53. 1868-1920. £105.
(2) Liebigs Annalen der Chemie und Pharmazie. Band 1-412 mit 8 Suppl. und Generalregister zu Band 1-380. 1832-1916. Teilweise Neudruck. Gleichmässig gebunden. £210.
(3) Monatshefte fur Chemie. Bd. 1-40 u. Reg. 1880-1920. £125.
(4) Chemisches Centralblatt. Jahrgang 1-67 1830-1896. Gleichmässig gebunden, selten schöne und komplette Serie. £400.

—ED.]

PERSONALIA

The University of Edinburgh has accepted a gift by Mr. J. A. Hood of the sum of £15,000 to endow a chair of Mining.

Prof. E. W. Washburn has been elected vice-president of the chemical section of the American Association for the Advancement of Science.

Mr. J. T. Troestel has resigned his position on the dust-explosion staff of the U.S. Bureau of Chemistry to become chief chemist of the American Refractories Co. at its Jobet, Ill., plant.

* * *

From Germany the deaths are announced of Prof. K. E. Bessel, formerly director of the Physical Technical Reichsanstalt, and of Prof. F. Neesen.

The death is announced of Mr. F. J. Lloyd, a well-known agricultural chemist, who had done valuable work on the feeding of animals for milk production and on cider-making.

NEWS AND NOTES

BRITISH INDIA

Final Forecast of the Sesamum Crop, 1922-23

A memorandum based on reports received from provinces which contained an average of 99·6 per cent. of the total area under sesamum states that the area under the crop is estimated at 4,847,000 acres (4,529,000 acres in 1921-22), and the yield at 428,000 tons (456,000 tons). Excluding Burma, these estimates of area and yield fall short of the corresponding estimates of last year by 12 and 17 per cent. respectively. No very favourable weather was reported, but the general condition of the crop is said to be fair.—(*Ind. Tr. J., Jan.* 25, 1923.)

FRANCE

Cream-of-Tartar Industry in France and Algeria

The wine districts of Southern France and Algeria are the world's largest sources of cream of tartar, the average annual production of argols being 10,000 tons. Of this quantity of argols (crystals which form on the wine casks and contain 75 per cent. of cream of tartar) some 5200 tons are exported to the United States, 2000 to England, 800 to Germany, and 2000 are consumed in France. The 18 cream-of-tartar factories in France had an annual production before the war of 6000 t., but now produce only 2000 t. In addition to the argol production some 15,000 t. of wine lees containing from 18 to 20 per cent. of cream of tartar are also available annually. The principal centre of the cream-of-tartar trade in France is Montpelier.—(*U.S. Com. Rep., Jan.* 15, 1923.)

GERMANY

Aphrogen, a New Saponin

Amongst the various products which Germany has in the past been obliged to obtain largely from abroad are the raw materials from which the naturally occurring class of glucosides, the saponins (*cf.* J. 1920, **39**, **281** A; 1921, **40**, 156 and 825 A), are extracted. Foreign supplies being now too costly, Germany has fallen back upon her own resources, and the firm of Otto Bärlocher, of Munich, has succeeded in obtaining from indigenous plant products a saponin, to which the name *Aphrogen* is given. Since the glucosides of this class possess in a marked degree the power of producing froths they are often added to beverages, and it has therefore been of importance to determine the physiological behaviour of *Aphrogen*. Toxicity and hæmolytic power are found not to run parallel, though in both respects, according to recent experiments by Dr. M. Mandelbaum, *Aphrogen* is much less active than its predecessors. It is therefore better suited than the latter for use in emulsions and beverages. Details of its extraction are not given.—(*Chem.-Z.*, 1923, p. 71.)

GENERAL

New Colloids Research Laboratory in Manchester

The *Manchester Guardian* reports that the Council of Manchester University has approved a scheme for establishing a Colloids Research Laboratory in the University. A sum of £11,842 has been subscribed and given to the University towards the endowment and cost of the equipment of the department. The Research Laboratory will be known as "The Graham Research Laboratory," and Mr. D. C. Henry, M.A., now Lecturer in Chemistry in the University, has been appointed Lecturer in Colloid Physics as from September next, and will take charge of the Laboratory.

Molybdenum Ores

This monograph, which is part of the series on Mineral Resources, with Special Reference to the British Empire, published by the Imperial Institute (John Murray, pp. 86, price 5s.), gives a useful account of the occurrence, characters and uses of molybdenum ores. Until recently the commercial use of molybdenum was practically limited to the manufacture of chemicals such as ammonium molybdate. Of late years molybdenum has, however, been used in steel making, in electrical and other work, and as a constituent of non-ferrous alloys of remarkable properties. Owing to the shortage of tungsten during the early part of the war, exploitation of molybdenum deposits was very active, as the consumption had greatly increased. The world's production of molybdenum in metric tons o metallic contents of concentrates during recent years is as follows :—

	1915	1916	1917	1918	1919	1920	1921
Australia	70·8	74·2	94·4	105·1	95·5	35·5	5
Bolivia	6·5	5·2	—	—	—	—	—
Canada	8·0	42·5	89·9	102·9	30·9	Nil	Nil
Chile	—	0·8	20·1	—	—	—	—
China	—	2·7	2·4	1·1	—	—	—
Korea	—	3·2	59·2	10·7	—	—	—
Japan	—	18·3	12·1	70·3	—	—	—
Mexico	—	—	—	14	1	0·3	2
Norway	72·3	73·1	82·1	84·9	—	—	—
Peru	1·3	3·1	3·8	1·3	2·5	1·0	—
Spain	5·2	26·7	—	—	—	—	—
Sweden	—	0·3	20·3	25·1	—	—	—
United States	82·4	93·8	158·8	390·8	135·2	15·0	Nil

Only two molybdenum minerals are of practical importance, viz., molybdenite and wulfenite. The concentration of wulfenite ores is comparatively simple, whereas molybdenite ores require concentration by water or oil flotation. Processes of extraction of the metal consist either in electric fusion, the aluminothermic method, or leaching (in the case of wulfenite) with an alkaline solution such as sodium sulphide. The ores are found in small quantities in the United Kingdom, but the chief deposits are in India, South Africa, Canada, and especially in Australia, deposits in Queensland and New South Wales having produced about half the world's output of molybdenum ores during recent years. Norway and the United States (Arizona) are also important producers. The monograph concludes with a list of references to the literature on molybdenum.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for February* 22)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Algiers	Lubricating oils	267
Brazil	Paint, oil, varnish, metals, tinplate	271
British India	Sheet glass, glycerin B.P., potassium iodide cryst. B.P. (tender for)	*
Canada	Iron sheet, tinplate, heavy hardware	224
	Brass and copper tubing, sheet and rods	†
Denmark	Scientific instruments, laboratory supplies	2724/F.F./C.C./2
Egypt	Oils, zinc and iron sheets, tinplate, copper, earthenware, copra	264
Italy	Crystal glass	234
,,	Hardware	235
Netherlands	Steel and copper wire	239
,,	Nickel-plated steel plate, nickel-plated tinplate	244
,,	Brass and copper sheet, iron and steel	246
,,	Pottery, china, glass	249
New Zealand	Crockery, hollow-ware	226
Rumania	Iron sheet, tinplate, tin, zinc, copper, lead	251
,,	Heavy chemicals, oils, waxes, vanillin	252
Spain	Pharmaceutical products	256
Straits Settlements, etc.	Druggists' supplies, patent medicines	266
Switzerland	Paper	262

* Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1.

† Canadian Government Trade Commissioner, 37, Basinghall Street, E.C. 2.

TARIFF CUSTOMS EXCISE

Belgium.—The export prohibition has been withdrawn from coke.

Czechoslovakia - Latvia. — The commercial treaty between these two countries is now in force.

Ecuador.—By a recent amendment to the customs tariff, the duties on certain vegetable oils, soap, etc., have been reduced, and those on " luxury " articles have been increased.

Fiji.—The export duty on copra is reduced from 15s. to 10s. per ton. Tinplate of British origin may be imported duty-free.

Finland.—The import and export duties leviable during 1923 are to be the same as in 1922. Increased duties, however, are applied to sugar, and iron and steel bars and reduced duties to certain wares of paper and china.

Germany (*Occupied Territory*).—Further measures of trade control are set out in the current issue.

Greece.—Crude coconut and palm oils are dutiable at double the former rate, and the duty on unspecified goods has been raised from 20 to 40 per cent. *ad valorem.* Alterations in the export duties affect turpentine, resin, oil, soap, and tartar.

Mozambique.—A copy of the new import tariff may be consulted at the Department.

Rumania.—Export prohibitions are applied to brass, zinc, linseed, paper (not printed), crude petroleum, petroleum residues, mineral grease, edible vegetable oils, and raw hides. Authorisation is required for the export of pig and cast iron, copper, caustic soda, paraffin wax, bones, cement, cellulose, scrap iron, ferro-manganese, glue, starch, and certain petroleum products.

South Africa.—A " dumping " duty has been imposed on cement imported from Belgium, Denmark and Holland. A special duty is leviable on imported Dutch superphosphates containing less than 17 per cent. available phosphoric acid.

Tunis.—The consumption duty on alcohol is raised from 850 to 1000 francs per hectolitre of pure alcohol, but denatured alcohols remain subject to a duty of 2 fr. per hl. of pure alcohol.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Exports of Coal

In reply to Mr. Shinwell, Lieut.-Col. Lane-Fox said that the export of coal from this country to France, Belgium, Italy, Germany and Holland for the fortnight ended February 10 exceeded the fortnightly average in the last quarter of 1922 by 52,000 tons.—(Feb. 15.)

Import Licences for Dyestuffs

Viscount Wolmer informed Major Attlee that the Dyestuffs (Import Regulation) Act, 1920, empowered the Board of Trade to charge for each licence a fee not exceeding £5 to cover the cost of administration. Fees actually charged were based on the value of the consignment to which the licence related, and ranged from 2s. 6d. on consignments of a value up to £100, to £5 on consignments exceeding £3000 in value.—(Feb. 19.)

The Shropshire Barytes Industry

Lieut.-Col. Lane-Fox, replying to Viscount Sandon, said he was aware of the precarious condition of the barytes industry in Shropshire.

The Ministry of Transport was inquiring as to the effect of railway rates on the industry. He was not aware how foreign competition could be overcome, but any proposals to that end would be considered.—(Feb. 19.)

Overseas Trade Department

The Prime Minister (Mr. Bonar Law) informed Mr. Darbishire that expenditure on the Department of Overseas Trade and its overseas services had been substantially reduced. In view of the importance of promoting our overseas trade, and having regard to representations received from the commercial community in favour of maintaining the Department, it was not intended to abolish it.—(Feb. 19.)

Home-grown Sugar-Beet

Replying to Mr. Wise, Mr. R. Sanders said in accordance with arrangements for the future amalgamation of the Kelham and Cantley sugar-beet factories, both factories would offer contracts for beet to the limit of their respective capacities, so that 6000 acres would be grown for Kelham and 9000 acres for Cantley. Although this area was nearly double that grown last year, many requests from farmers had had to be refused. The Government had approved a scheme for raising capital to alter and improve the Kelham plant to enable it to deal efficiently with this year's crop and for reorganising the company's finances. For this reason the amalgamation of the two companies was postponed until the end of the present season, when the results of operations at both factories would be available.—(Feb. 19.)

Medical Research Council

In a written answer to Sir H. Nield, Mr. Baldwin stated that, in view of the magnitude of the national expenditure due to disease, and the vital importance of measures calculated to improve the health and efficiency of the industrial population, the Parliamentary Grant-in-Aid of £130,000 per annum to the Medical Research Council was not excessive, and its detailed allocation, whether for publishing Reports or other purposes, might be left to the discretion of the Council. Considerable value was attached to the work of the Industrial Fatigue Research Board in the industrial world.—(Feb. 19.)

National Physical Laboratory

Mr. E. Wood, answering Sir P. Newson, said that in 1913–14 the National Physical Laboratory received Treasury Grants totalling £21,150, and payments from Government Departments for services rendered amounting to £32,546. The staff then numbered 202 and cost £27,323. According to the estimate for 1922–23, the staff of 490 cost £145,500, and sums received for services rendered would total £89,000, the net cost to the Department of Scientific and Industrial Research being £75,000.—(Feb. 21.)

GOVERNMENT ORDERS AND NOTICES

Safeguarding of Industries Act, 1921

The Treasury has issued an Order dated February 15, under Section 10 of the Finance Act, 1922, exempting from duty certain articles which contain ingredients dutiable under the Safeguarding of Industries Act, Part I., on account of the small value of the dutiable ingredients or parts in comparison with the total value of the whole articles. Articles thus exempted from duty include: Ornamental articles, otherwise dutiable only by reason of containing lamp-blown ware as a part; unmedicated toilet oils containing dutiable perfumes, fireworks, sporting cartridges, bath salts, grease paints, and toilet preparations, which contain dutiable chemicals as a part or ingredient; toilet and medicinal preparations, disinfectants, and flavouring mixtures, which contain dutiable chemicals, provided that the value of the dutiable ingredients in any article does not exceed 10 per cent. of the aggregate value of the ingredients of the article.

Permitted Explosives

The Secretary for Mines has made an Order dated February 15, 1923, varying the list of permitted explosives named and defined in the Explosives in Coal Mines Order of September 1, 1913, and in subsequent amending orders.

COMPANY NEWS

THE SOUTH METROPOLITAN GAS CO.

The ordinary general meeting was held on February 14, Dr. Charles Carpenter presiding.

In discussing the questions relating to gas supply which are now before the public, Dr. Carpenter said that the necessity for recovering benzol and toluol from coal gas for high-explosives manufacture during the war led to complaints about the quality of the gas. As a result the Fuel Research Board investigated the matter, and suggested that gas should be sold by its thermal value, leaving the gas undertakings free to adopt the standard of heat quality best suited to the circumstances of manufacture. The consumer was protected by the installation of recording devices, many of which, he hoped, would soon be put to work. With regard to the safety of gas supply, the truth was that, whether gas, electricity or candles were used for lighting, certain risks would attend their use, but never outweigh their advantages. The dangers of carbon monoxide in coal gas were exaggerated as coal gas containing it had a characteristic smell, It was noteworthy that even the large municipal corporations supplied gas containing carbon monoxide. The company still had to pay double the pre-war price for coal, and prices of by-products had fallen heavily. For the first time since 1914 the pre-war dividend of 5½ per cent. had been reached.

REVIEWS

Heat Transmission. Technical Records of Explosives Supply, 1915–1918. *Ministry of Munitions and Department of Scientific and Industrial Research. No. 9. Pp. iv.+48. H.M. Stationery Office,* 1922. *Price* 5s.

The prefatory note states : " This is the 9th and last of a special series of Reports, which have been published in order to make available, for the benefit of the industries concerned, the results of scientific and industrial value contained in the technical records of the Department of Explosives Supply of the Ministry of Munitions." This note sufficiently explains the scope of the work, which has been compiled by Mr. W. McNab and edited by Dr. A. W. Porter.

The book contains three sections, the first being theoretical, the next experimental, and the third being an application of the principle to certain special cases. There are several alignment charts, from which overall co-efficients of heat transmission can be calculated graphically, and there are charts dealing with the co-efficient of transmission for pipes carrying water and gases respectively. The theoretical section is due to Dr. Porter, and is not intended to carry the theory of heat transmission beyond that attained in recent text-books, but is sufficient only to introduce the symbols and formulæ required for the study of the experimental data.

When the Department of Explosives Supply undertook to erect a number of important factories, in which heating and cooling of liquors and gases constituted so large a number of problems to be solved, there was found to be an insufficiency of data upon which to design such plant with certainty. Accordingly, a number of experiments was made, covering the question of cooling acid, the use of lead coolers and superheaters in denitration plants, the effect of stirring on rate of cooling, the heat transfer in surface condensers, the question of surface losses, etc. The data thus obtained have been collected and interpreted in the light of the theory, and a number of valuable co-efficients have been determined, some of which are applicable only to special cases, but others have a much wider significance, which renders the book of all-round value as a work of reference which should be in the hands of every designer who has to deal with heat-transmission problems.

In spite of all the published data regarding heat transmission, there is still a great lack of connected data from which results for any definite set of circumstances can be interpolated, and this work carries the solution of heat transmission problems a stage further than any existing book ; but the theory is still far from complete, and there is still scope for a great deal more work on this subject.

On page 8 the law of heat transmission from fluid to metal or *vice versa* is stated, but the constant involved in the equation is omitted, although the formula has been used in constructing the chart (Fig. 4) for the co-efficient of heat transmission for pipes carrying gases. By working backwards this constant is found to be between 0·21 and 0·22. From the reviewer's experience this constant is probably rather low, and should be nearer 0·24.

The experimental section would have been increased in value if the overall co-efficients obtained had been compared methodically with the theoretical value obtained from the formula, and there are wide discrepancies in the results tabulated in Fig. 7.

One important omission is the performance of concentric tube interchangers—a method of heat transfer which is coming more and more into use and upon which reliable data are badly needed. The theory is touched upon and the statement is made regarding the " equivalent diameter " of an annulus, that " it would seem fair to treat it as equivalent to a pipe of diameter equal to the difference of the diameter of its outside and inside surface." One may ask " Why ? " especially if the annulus is narrow compared with the pipe diameters. Experimental data are not available to support this, and the point still needs elucidation.

It is important to note that the " equivalent diameter," when the formula is based on " heat/foot^2 " is not the same as the " equivalent diameter " when the formula is based on " heat/foot run." Where the sectional area of the inner pipe equals the sectional area of the annulus, then, if the equivalent diameter in the formula based on heat/foot^2 is 2×annular width, the " equivalent diameter " based on heat/foot run is 13·5×annular width.

In dealing with fundamental principles on page 1 the temperatures t_1 and t_2 should surely be the *metal* temperatures not the temperatures " just inside and just outside." From the illustration t_1 and t_2 would appear to refer to the fluid temperatures. Again the co-efficient of transmission is calculated per *square foot*, but it should be noted that in many cases in practice where relatively thick pipes are used, the areas inside and outside are very different. In such cases the *mean* area should be used, and even then the result must be regarded as approximative. Would it not have been better to adopt the method of employing coefficients which give the heat transmission per *foot run* of pipe ? Thus :—

If k_l = C.H.U/hr./ft. run/° C. for inner film
k_o = ,, ,, for outer film
k_m = ,, ,, for metal =

$$\frac{2 \quad K}{\log_e \quad b/a}$$

Then, if k=overall co-efficient,

$$\frac{1}{k} = \frac{1}{k_l} + \frac{1}{k_o} + \frac{1}{k_m} \text{ exactly,}$$

whilst the corresponding equation on the surface basis is only an approximation.

It will need care to avoid being misled or puzzled by some typographical errors which should be removed in any succeeding edition. For example: On page 9, line 14, t_1 should be t; on page 11, in the diagram t Hot t should be t_0 Hot t; on page 12, $(t_0'—t')/(t_0'—t)$ should be $(t_0'—t')/(t_0—t)$; on page 15, the numerator and denominator of the expression within the square brackets should be reversed, and the third line from the bottom should read: (Thermal cond.) ×(press.×dens. at 1 atm) $^{\frac{3}{4}}$/ (Viscosity) $^{\frac{1}{4}}$.

On page 16 the index $\frac{3}{4}$ should be outside the bracket and not applied to velocity only. Further, it is unfortunate that the symbols used on page 3 in relation to Fig. 1 have different meanings from those used on the previous page, and that H has a different meaning. For Fig. 1 k, k_1, k_2 are not defined; they are

k_1=co-efficient of transmission for one film.
k_2= ,, ,, other ,,
$\frac{k}{b—a}$= ,, ,, metal.

Reverting to the chart of Fig. 4, in applying this to an interchanger where the temperature varies along the interchanger, Fig. 4 gives the coefficient of heat transmission for any particular temperature. As stated on the top of page 16, the mean value of the coefficient for the whole interchanger can be approximately obtained by taking the mean value of the temperature. It might be noted that the coefficient of transmission will vary only slightly even for the great temperature changes, because

$$H = CK\left(\frac{v\,\delta\,D}{\mu}\right)^{\frac{3}{4}} \quad \text{where}$$

H=CHU/hr/ft run/°C, and in ordinary cases $v\delta D$ is nearly constant along a given interchanger, so that $H=C'K/\mu^{\frac{3}{4}}$

Now $K/\mu^{\frac{3}{4}}$ varies only slightly with change of temperature; hence a nearly accurate value of H is obtained by employing the *mean* temperature.

In conclusion, the Department of Scientific and Industrial Research have done wisely in publishing for the general benefit this book of valuable data, and it will be of real assistance in all industrial establishments where heat-transmission problems are handled scientifically.

H. A. HUMPHREY

LE CAOUTCHOUC. *By* PAUL BARY. *Les Colloïdes dans l'Industrie. Pp. vi+255. Paris: Dunod,* 1923. *Price* 29 *francs.*

The study of colloids is a branch of science which has made rapid developments in recent years, and in this connexion rubber is one of the substances which have attracted most attention. It does, in fact, appear certain that the colloidal state of rubber forms the key to its remarkable properties and reactions, and must be the true basis for explaining its behaviour in the various technical processes involved in its production and manufacture—from the coagulation of the latex to vulcanisation and regeneration.

The author has undertaken the difficult task of presenting a study of the chemistry and technology of rubber from the point of view of its colloidal nature, and his efforts have been attended with no small measure of success. The work consists of a systematic survey of existing knowledge of the subject, including brief abstracts of most of the recent literature of importance, which make it a useful reference book. Wherever opportunity occurs the author attacks his subject from the colloidal-chemical aspect, and in so doing displays a great deal of originality, thus providing some most interesting additions which open up a vast field of thought.

The first part deals briefly with rubber latex, its constituents, and methods of coagulation, and is followed by chapters on chemical properties and constitution, physical properties, and vulcanisation, with a concluding chapter devoted to synthetic rubber, regenerated rubber, and substitutes. The author is seen particularly to advantage in his treatment of such subjects as the swelling and process of solution of rubber in Chapter III; the theory of vulcanisation, reversibility of the reaction between rubber and sulphur, and the mode of action of accelerators in Chapter IV; and the theory of devulcanisation in Chapter V, which contains lists of patented processes for the synthesis of isoprene and artificial rubber, and for the regeneration of rubber. Judged from the economic standpoint, the importance of these seems hardly sufficient to merit the labour which must have been expended in compiling them, and a much more useful purpose would have been served by a similar much-needed *résumé* of the patent literature concerning a number of other subjects of far greater importance at the present time; such, for example, as accelerators of vulcanisation and vulcanisation processes.

It is unfortunate that so many errors have escaped detection during correction of the proofs. The following are some which have been noted:—In the reference on p. 17 to H. P. Stevens' work, "4, p. 1960, 1922," should read "4, p. 196, 1922"; on p. 128, "H. D. Porritt" should read "B. D. Porritt," and Porritt is not indexed; on p. 135, line 4, "et" should read "est"; on p. 138, the structural formula needs correction; on p. 190, "Casparia" should read "Caspari"; on p. 194, 7th line from the bottom, "puisser" should read "puisse"; on p. 197, "Shart" should read "Short"; and in several instances the abbreviation "Chem. Ind." is incorrectly used for "Jour. Soc. Chem. Ind." Apart, however, from these minor defects, the book is well and clearly written, and should prove a valuable addition to the libraries of all interested in the elucidation of the intricate problems of the chemistry and technique of rubber.

R. N. JOHNSON

OPTICAL METHODS IN CONTROL AND RESEARCH LABORATORIES. VOL. I. *By* J. N. GOLDSMITH, S. JUDD LEWIS AND F. TWYMAN. *Second Edition. Pp. iv+56. London: Adam Hilger, Ltd.*, 1923. *Price* 1*s*. 6*d*.

The optical properties—*e.g.*, refractive index, emission or absorption spectrum, and specific rotatory power of a substance are physical qualities characterising the molecule of the substance. These various characteristics can, in general, be determined with great accuracy; indeed, certain optical measurements of the kind referred to are among the most precise known to physical science. It is not surprising, therefore, that the attention of chemists and physicists was, early in the history of applied optics, turned to the development of instruments for the rapid and easy determination of these characteristics. Refractometers and polarimeters are to-day part of the equipment of most research and technical laboratories. We would say that their very familiarity appears to be responsible for a certain contempt of the conditions of use under which alone they are capable of affording useful and accurate information. In addition to instruments of the above types, spectrometers, spectrographs, and spectrophotometers, both for the visible and invisible regions of the spectrum have long been available and are now finding a limited application in chemical technology. The financial potentialities of the technical application of spectrophotometry may be instanced by a case taken from the work under review, where, on p. 21, we read that during 1914–1919 a saving reckoned in tens of thousands of pounds was effected in the cost of dyes by the use of a spectrophotometer. The main purpose of the book is to afford information concerning the directions in which refractometers, polarimeters, spectrographs and spectrophotometers can be of value to the technical chemist. The authors' and publishers' high qualifications for this task are indisputable, and the reviewer heartily commends the work to the notice of all technical chemists. The work contains a wealth of references to literature dealing with the application of optical methods of investigation in the most unexpected directions. Thus, to take a few illustrative applications at random, we find particulars of the detection of as little as 0·0000001 gm. of mercury in explosives, the quantitative determination of from 0·004 to 0·216 per cent. of lead in copper, the determination of a few hundredths of one per cent. of nitrogen peroxide in gases resulting from the decomposition of gun cotton, etc., the analysis of mixtures of methyl and ethyl alcohols, and of mixtures of benzene and cyclohexane, the detection of naphthalene in benzol, and the discrimination of coal-tar and coke-oven tar creosotes from blast-furnace and water-gas tar creosotes. Other applications are legion.

Certain points of adverse criticism will, it is hoped, be avoided in future editions. No index is provided to the book, a defect limiting very seriously its usefulness. A uniform style has not been maintained throughout the book. In one part references are given as footnotes; in another they are embodied in the text or at the end of the chapter. One part is apparently the work of the reputed authors; another is very clearly the work of the publishing house. Messrs. Adam Hilger, Ltd., have a world reputation second to none as makers of optical instruments. Certain of their publications are of an equally high standing. The growing tendency in English scientific literature of a certain type, issued since the war, to attempt to run pure science and literature of the trade-circular type in joint harness is to be deprecated. Appreciation of the scientific part of the brochure under review is expressed above, but one is sorely tempted to modify this when confronted with such statements as the following (p. 12):—"Anyone purposing to commence serious visual spectrum analysis without one of the modern 'Wavelength' forms (introduced by Adam Hilger, Ltd., in 1904) would be well advised to employ his time more usefully." The authors and Messrs. Hilger are capable of something very much better than that. Some continental firms—mention may be made of the Siemens-Konzern—are responsible for scientific publications worthy of ranking with what is best in scientific literature. Messrs. Hilger, Ltd., are amongst the firms who could do the same for English science. The book could be extended, its obvious defects removed and its usefulness very much increased. One thing is certain, it could not then be issued at the modest price which commends the present edition. Perhaps the reviewer has been misled and the publication is the latest form of post-war trade circular; if so, it is the best with which he is acquainted, and his advice to chemists and physicists is—get it!

J. S. G. THOMAS

"WHERE TO BUY" EVERYTHING CHEMICAL. *Pp.* 200. *London: S. Davis & Co., January*, 1923. *Price* 2*s*. 6*d*.

This Index, the second so far issued, is published in January and July of each year, and provides a useful guide to the principal sources of supply of chemicals, chemical plant and apparatus, each of these sections being treated under a separate heading. Under the name of each chemical will be found the names and addresses of the principal manufacturers or merchants arranged alphabetically to facilitate reference. The wide range of chemicals and chemical plant listed provides an impressive tribute to the importance of the chemical trade in this country. The trade names of various chemical products are given in an appendix. This publication is better than most others of its kind, but as usual some of the principal manufacturers are omitted from the respective lists and their places taken by agents and merchants who do not specialise in the product.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

There is in general little or no change to report in prices during recent weeks. Unfortunately the tone of the market has gone decidedly pessimistic and has not fulfilled the promises of the earlier weeks of the year. The effect of publicity and the bringing together of buyers and manufacturers at the British Industries Fair can only have a beneficial effect, and by displaying the line upon which various firms are developing will stimulate others to make the fullest use of new products which are being put on the market.

Acid Acetic, 40% tech.	£22 per ton. Tone still very firm and supplies none too plentiful.
Acid Hydrochloric	4s. to 5s. d/d.
Acid Nitric, 80° Tw.	£25 per ton d/d. Not in much demand.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw., is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton. Position well maintained but somewhat quieter than at the earlier part of the year.
Arsenic (White)	£65-£70 per ton. Tone slightly less firm.
Bisulphite of Lime	£7 per ton, packages extra and returnable.
Bleaching Powder	£10 10s. per ton d/d. No change in demand, which is still poor.
Calcium Chloride	£6 per ton d/d. In poor request.
Copper Sulphate	£26 10s. per ton f.o.b.
Potash Caustic, 88/90%	£29-£30 per ton. No change.
Potass. Bichromate	6¼d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton. No change in prices, but greater quantities are offered for spot delivery.
Soda Caustic, 76%	£20-£21 per ton. No change.
Soda Crystals	£5 10s. per ton carr. paid. Demand well maintained.
Sod. Acetate, 97/98%	£23 10s. per ton. In fair demand. Price firm.
Sod. Bicarbonate	£10 10s. per ton. Inquiry quite good.
Sod. Bisulphite Powder, 60/62%	£19-£20 10s. per ton f.o.b. or f.o.r. London.
Sod. Chlorate	Prices of foreign supplies vary, and buyers are not keen on placing orders for forward delivery.
Sod. Nitrite	£30 per ton 100% basis d/d.
Sod. Sulphide, solid 60/62	£15 per ton. Market unsteady and demand shows no improvement.
Sod. Sulphite, Pea Cryst.	£17-£17 10s., 1-cwt. wooden kegs included.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£9 per ton d/d.
Grey, 80% basis	£18 10s. to £20 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£9 10s.-£10 per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 6d. ,, ,, Unrefined.
Wood Naphtha—	
Miscible	6s. 6d. ,, ,, 60% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£5 per ton d/d.
Brown Sugar of Lead	£38 per ton d/d.

TAR PRODUCTS

Acid Carbolic—		
Crystals	1s. 3d.-1s. 4¼d. per lb. Very active demand, especially from Japan. Price has upward tendency.	
Crude 60's	3s. 8d.-3s. 9d. per gall. Good demand.	
Acid Cresylic—97/99	2s.-2s. 2½d. per gall. Not much business moving.	
Pale 95%	1s. 11d.-2s. 2d. per gall.	
Dark	1s. 9d.-2s. per gall.	
Anthracene Paste, 40%	4d. per unit per cwt. Price nominal. No business.	
Anthracene Oil—		
Strained	9d.-11d. Fair inquiry.	
Unstrained	8¼d. per gall.	
Benzole—		
Crude 65's	1s. 1½d.-1s. 2d. per gall.	
Standard Motor	1s. 8d.-2s. per gall.	
Pure	2s.-2s. 2d. per gall.	
Toluole—90%	1s. 9d.-1s. 11d. per gall.	
Pure	2s. 1d.-2s. 3d. per gall.	
Xylol	3s. 3d. per gall.	
Creosote—		
Cresylic 20/24%	10½d.-1s. 1d. per gall. Moderate demand.	
Middle Oil	8½d.-9½d. per gall.	Good demand.
Heavy	8½d.-9½d. ,, ,,	
Standard Specification	8½d.-9½d. ,, ,,	
Naphtha—		
Crude	9d.-9¼d. per gall.	
Solvent 90/160	1s. 7d.-1s. 9d. per gall. Little business doing.	
Solvent 90/190	1s. 7d. per gall. Fair demand.	
Naphthalene Crude—		
Drained Creosote Salts	£6-£9 10s. per ton. Supply short.	
Whizzed or hot pressed	£9 10s.-£12 10s. per ton.	
Pitch, Medium Soft	157s. 6d. to 160s. per ton f.a.s. Manchester. Numerous inquiries. Market still firm.	
Pyridine—90/140	10s. 6d.-12s. 6d. per gall. Not much business.	
Heavy	8s.-9s. per gall. Price nominal.	

INTERMEDIATES AND DYES

Business in Aniline Dyestuffs has been on about the same level as reported last week. Although there has not been that increase in the volume of trade which has been rather noticeable during the last three or four weeks, at the same time there has been no falling off. The outlook is distinctly better.

Prices remain firm, with a slight advance in one or two outstanding colours. It is quite anticipated that owing to the large rise in price of some of the raw materials, that in other cases prices will have to be advanced to cover the rise.

Acetic Anhydride	1s. 5d. 100% basis.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 7½d. lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride—Anhy.	1s. per lb. d/d.
Aniline Oil and Salts	10d. per lb. naked at works.
Antimony Pentachloride	1s. 1d. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrophenol	£140 per ton.
Dinitrotoluene—48/50	8d.-9d. naked at works.
66/68	1s. 2d.-1s. 3d. naked at works
Diphenylamine	4s. per lb. d/d.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Metanitraniline	5s. 6d. per lb. d/d.
Meta Phenylene Diamine	5s. 6d. per lb. d/d.
Meta Toluylene Diamine	5s. per lb. d/d.
Monochlorbenzol	£70 per ton.
α-Naphthol	2s. 9d. per lb.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
p-Nitraniline	2s. 8d. per lb. d/d.
Nitrobenzene	7½d. per lb., drums extra.
Nitronaphthalene	1s. per lb. d/d.
Naphthionate Soda	2s. 8½d. lb. 100% basis d/d.
Orthonitrochlorbenzol	2s. per lb. 100% basis d/d.
p-Chlorphenol	2s. 10d. per lb.
Paradichlorbenzol	£55 per ton.
Paranitrophenol	1s. 9d. per lb. 100% basis.
Parachloraniline	3s. per lb. 100% basis.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
Para Phenylene Diamine	12s. per lb. 100% basis d/d.
Para Toluidine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid Acetic, 80% B.P.	£45-£47 per ton. Tendency for prices to harden further
Acid Acetyl Salicylic	3s. per lb. for good crystal.
Acid Benzoic	2s. 3d. per lb. Will probably advance further in price.
Acid Boric B.P.	£61 per ton Crystals, £65 per ton Powder, packages in 2-cwt. bags.
Acid Citric	1s. 8d. to 1s. 8½d. per lb., less 5%. Fair demand.
Acid Gallic	3s. per lb.
Acid Pyrogallic, cryst.	5s. 6d. per lb.
Acid Salicylic	1s. 7d.-1s. 9d. per lb.
Acid Tannic	3s. 3d. per lb. No change.
Acid Tartaric	1s. 2½d.-1s. 3d. per lb., less 5%. Fair demand still maintained.
Amidol	9s. per lb.
Amidopyrin	12s. 6d. per lb. for quantity.
Ammon. Benzoate	3s. per lb. for good makes.
Ammon. Sulphocyanide, recryst.	2s. 6d. per lb.
Barbitone	13s. per lb. Price advancing.
Benzonaphthol	5s. per lb.
Bismuth Salts	Price per lb. for cwt. lots are as follows:—Carbonate, 13s., Citrate 11s. 7d., Nitrate cryst. 6s. 11d., Oxide 14s. 5d., Salicylate 10s. 5d., Subchlor 12s. 8d., Subgallate 9s. 6d., Subnitrate 11s.
Calcium Lactate	2s. per lb. Steady.
Chloral Hydrate	3s. 9d.-4s. per lb., according to quantity and holder.
Formaldehyde, 40%	£90 to £92 10s. per ton.
Guaiacol Carbonate	8s. per lb.
Hexamine	4s. per lb. Available supplies rapidly absorbed.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate	B.P. 2s. 5d. per lb. (Green, 3s. 1d. per lb. } Fair Demand.
Magnesium Carbonate, light commercial	£37 per ton.
Magnesium Oxide—	
Light, commercial	£85 per ton.
Heavy, commercial	£28 per ton.
Menthol	37s. per lb., less 2½% for original cases. Small quantities 37s. 6d. nett.
Methyl Salicylate	2s. 3d. per lb. for water-white product in glass containers.
Methyl Sulphonal	13s. per lb.
Paraldehyde	1s. 6d. per lb., will probably be considerably advanced in price.
Phenacetin	5s. per lb., quiet and steady.
Phenazone	7s. per lb. No change.
Phenolphthalein	4s. 9d. per lb. Slightly lower.
Potass. Bitartrate, 99/100% (Cream of Tartar)	98s.-100s. per cwt., less 2½% for ton lots. Market very firm.
Potass. Ferricyanide	4s.-4s. 3d. per lb.
Potass. Iodide	15s. 8d. per lb. for cwt. lots. Cases free. Demand still good.
Potass. Metabisulphite	7d. per lb.
Potass. Permanganate	9d. per lb.
Quinine Sulphate	2s. 2d.-2s. 4d. per oz.
Resorcin	5s. per lb. now quoted for good "white."
Salol	2s. 3d.-2s. 6d. per lb., advancing in sympathy with Salicylates.
Sod. Benzoate	2s. 3d. per lb., with continental quotations very much higher.
Sod. Citrate—	
P.B.C.	2s. per lb.
U.S.P.	2s. 3d. per lb.
Sod. Hyposulphite,—Photographic	£15-£17 per ton.
Sod. Salicylate	2s. 3d. fpr powder, 2s. 4d. for crystals. These prices show little profit to the manufacturers and higher rates are expected in the near future.
Sod. Sulphite—Anhydrous	£27 10s.-£28 10s., according to quantity, f.o.r. London, drums included.
Sod. Sulphocarbolate	1s. 5s. per lb., higher.
Thymol	19s. per lb.
Zinc Sulphocarbolate	1s. 6d. per lb., advanced to.

PERFUMERY CHEMICALS

Amyl Acetate	2s. 3d. per lb.
Amyl Butyrate	8s. ,,
Amyl Salicylate ..	3s. 3d. ,,
Anethol (melting point 21°/22° C.)	4s. 6d. ,,
Benzyl Acetate (from chlorine-free Benzyl Alcohol)	3s. ,,
Benzyl Alcohol free from chlorine)	3s. ,,
Benzaldehyde, free from chlorine	3s. ,,
Benzyl Benzoate, 19·5° C.	3s. ,,
Cinnamic Aldehyde, 98/100% Natural ..	14s. 9d. ,,
Coumarin	12s. 6d. ,,
Citronellol	22s. 6d. ,,
Citral, 100%	9s. 6d. ,,
Ethyl Phthalate ..	4s. 3d. ,,
Eugenol 100%	11s. ,,
Geraniol (Palmarosa) ..	30s. ,,
Geraniol	5s. 6d.-12s. 6d. per lb.
Heliotropine	5s. 9d. per lb.
Iso Eugenol	18s. 6d. ,,
Linalol ex Bois de Rose ..	21s. ,,
Linalyl Acetate	22s. 6d. ,,
Methyl Benzoate ..	8s. 6d. ,,
Musk Xylol	8s. 9d. ,,
Phenyl Ethyl Acetate ..	10s. ,,
Phenyl Ethyl Alcohol ..	17s. 6d. ,,
Rhodinol	45s. ,,

ESSENTIAL OILS

Anise Oil, Red Ship Brand	2s. 1d.
Bourbon Geranium Oil ..	26s. 6d. for shipment.
Cananga Oil, Java ..	9s., firm.
Cinnamon Oil Leaf ..	4d. per oz.
Cassia Oil, 80/85% ..	8s. 3d.
Citronella Oil—	
Java, 85/90% ..	3s. 9d.
Ceylon	3s. 6d.
Clove Oil	8s. 3d.
Eucalyptus Oil, 70/75%	1s. 8d.
Lavender Oil, Mont Blanc 38/40%	12s. 6d.
Lemon Oil, spot ..	3s. New crop for shipment 2s. 11d.
Orange Oil, sweet, spot ..	10s. New crop for shipment 10s. 6d.
Otto of Rose Oil—	
Anatolian	24s.
Bulgarian	26s.
Palma Rosa Oil ..	17s. 6d.
Peppermint Oil—	
English, Mitcham ..	80s.
Wayne County ..	13s.
Japanese	6s. 9d.

TRADE NOTES

Trade Publications

Electrometric Apparatus for Determining Hydrogen Ion Concentrations.—We have received from Messrs. A. Gallenkamp and Co. a copy of their list No. 80 of Electrometric Apparatus for Determining Hydrogen Ion Concentrations. The list contains useful descriptions of the apparatus and the methods of working, and should be found useful to all those who have to carry out determinations by this process.

Aluminium.—We have received a small booklet (pp. 80, price 5s.) from the British Aluminium Co., Ltd., giving a collection of useful data on the physical, mechanical, and other properties of aluminium. In view of the ever-increasing use of aluminium in the electrical and other industries, this pocket book should prove of great utility, as the tables provided appear to cover most of the data required by those utilising this valuable metal.

PUBLICATIONS RECEIVED

OPTICAL METHODS IN CONTROL AND RESEARCH LABORATORIES. *By* DR. J. N. GOLDSMITH, DR. S. JUDD LEWIS *and* F. TWYMAN, *F. Inst. P. Vol. I. Pp. iv*+56. *Second edition. London: Adam Hilger, Ltd.,* 1923. *Price* 1*s.* 6*d.*

MANUEL PRATIQUE DE LA FABRICATION DES ENCRES. *By* L. DESMAREST *and* S. LEHNER. *Bibliothèque des Actualités Industrielles, No.* 65. *Third edition, revised and enlarged. Pp.* 372. *Paris: Gauthier-Villars et Cie.,* 1923. *Price* 12 *fr.*

THE STRUCTURE OF ATOMS. *By* PROF. ALFRED STOCK. *Translated from the second German edition, revised and enlarged, by* S. SUGDEN, M.Sc. *Pp. viii*+88. *London: Methuen and Co., Ltd.,* 1923. *Price* 6*s.*

DYES AND THEIR APPLICATION TO TEXTILE FABRICS. *By* A. J. HALL. *Pitman's Common Commodities and Industries. Pp. ix*+116. *London: Sir Isaac Pitman and Sons, Ltd.,* 1923. *Price* 3*s.*

METHOD FOR THE IDENTIFICATION OF PURE ORGANIC COMPOUNDS BY A SYSTEMATICAL ANALYTICAL PROCEDURE BASED ON PHYSICAL PROPERTIES AND CHEMICAL REACTIONS. *By* S. P. MULLIKEN, PH.D. *Vol. IV. Pp. vii*+238. *New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.,* 1922. *Price* 30*s.*

PUBLICATIONS OF THE UNITED STATES BUREAU OF MINES, *Department of the Interior. Washington: Government Printing Office,* 1922:—

COKE-OVEN ACCIDENTS IN THE UNITED STATES DURING 1921. *By* W. W. ADAMS. *Technical Paper* 318. *Pp.* 34. *Price* 5 *cents.*

ANALYSES OF KENTUCKY COALS. *Technical Paper* 308. *Pp.* 92. *Price* 10 *cents.*

COAL-DUST EXPLOSION TESTS IN THE EXPERIMENTAL MINE, 1913 TO 1918 INCLUSIVE. *By* G. S. RICE, L. M. JONES, W. L. EGY, *and* H. P. GREENWALD. *Bulletin* 167. *Pp. xxii*+639. *Price* $1.

ELECTRIC BRASS FURNACE PRACTICE. *By* H. W. GILLETT *and* E. L. MACK. *Bulletin* 202. *Price* 50 *cents.*

NATURAL-GAS MANUAL FOR THE HOME. *By* R. A. CATTELL. *Technical Paper* 325. *Price* 10 *cents.*

PREPARATION OF LIGHT ALUMINIUM-COPPER CASTING ALLOYS. *By* R. J. ANDERSON. *Technical Paper* 287. *Price* 10 *cents.*

STRONTIUM MINERALS (1913—1919). *The Mineral Industry of the British Empire and Foreign Countries. Imperial Mineral Resources Bureau. Pp.* 12. *H.M. Stationery Office,* 1923. *Price* 4*d.*

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, MARCH 9, 1923 No. 10

EDITORIAL

THE controversy—if one may so describe it—between Sir William Pope and Sir Arthur Colefax has been most interesting to read. Their studies, traditions and points of view differ so entirely that they hardly come to really close quarters. One of the earliest writers on the atomic theory tells us how delightful it is to watch a fight without sharing oneself in the danger. There is a sweetness in seeing the evils from which you are yourself exempt. This particular contest is between two champions, each of whom has made good points in that branch of learning in which he is most skilled and has demolished the arguments which he supposes the other to have put forward in that branch. Sir William has given a proof that calcium carbide is a synthetic organic compound, so closely reasoned, so well supported by evidence and so lucidly explained that it seems incontestable. Probably both agree that the Referee has rightly come to a wrong conclusion. How can such a catastrophe be avoided in the future? Sir Arthur claims that the learned Referee gave a true decision on the evidence before him, and Sir William admits that this is so.

* * *

Few chemists will dispute Sir William's conclusion; few lawyers will dispute Sir Arthur's. Some points remain undecided, and as we occupy a position in which we are not biassed by any profound knowledge on either side, we appointed ourselves a court of appeal, and having written on the back of the last number of our JOURNAL, *Curia advisare vult*, we have given the matter our best attention, and from the lofty and serene position which Lucretius describes in the passage we first mentioned we deliver our considered judgment:

A Referee who is impartial but not deeply versed in chemistry is very much handicapped in weighing chemical evidence. He would come to a sounder judgment on purely chemical controversies if he were assisted by a chemist who would approach the matter in a judicial frame of mind. Such chemists could be found. So, too, a chemist confronted with a number of conflicting legal opinions would be well advised to consult a lawyer who could do more than add up the witnesses on each side and decide with the majority. Quality, as well as quantity, must be considered, and the amateur finds it difficult to appraise the witnesses unless he can find a skilled assessor to help. Even in the highest legal circles these differences may be detected, and it is possible that among chemists some discrimination should be made in nice points of learning. Did not Lord Bowen say of a brother judge?—"To go to the Court of Appeal with a judgment of ——'s in your favour is like going to sea on a Friday. It is not necessarily fatal, but one would rather it had not happened."

Had Sir William and Sir Arthur chosen to argue whether the decision of the Referee was proper in the circumstances, much might have been said. But they agree on this, nor is there any obvious conflict of opinion as to the wording of the schedule to the Act.

We cannot imagine that decisions arrived at in the same manner as the calcium carbide decision will weigh with chemists, and we hope that future inquiries will be conducted with a greater degree of co-operation between the law and chemistry than has hitherto prevailed. We have ignored the debating points which each knight has scored over the other; if they will consult with us in our private room, we think they might probably agree on some joint recommendation to a higher authority which would tend to a more convenient procedure in the future.

Each party is at liberty to bring the matter before us again.

This seems to be a period of centenaries: it is about a hundred years since Pasteur was born, it is about a hundred years since Jenner died and it is about a hundred years since Faraday discovered benzene. The March number of *The Indian and Eastern Druggist* has an interesting short article on Claude Louis Berthollet, who died near Paris in November, 1822. Berthollet following work done by Priestley, showed that ammonia was composed of one part of nitrogen combined with three parts of hydrogen, and he helped to establish the use of chlorine as a bleaching agent. He discovered the chlorates and suggested the use of potassium chlorate as a detonator. A terrific explosion at Essonnes, near Paris, put an end to this investigation. Berthollet escaped the fury of the French Revolution which terminated the life of Lavoisier. When things were a little quieter he became a Professor of Chemistry, but left his work to follow Bonaparte through his campaign in Egypt and Syria. He published in 1781 a book on "Elements of the Art of Dyeing," in 1801 "Researches on the Laws of Affinity," and in 1803 his "Essay on Chemical Statics." In his later years he retired to Arcueil, where he used to meet Chaptal, Gay Lussac and other chemists. After the restoration of the monarchy he was raised to a seat in the Chamber of Peers and died in November, 1822. We read the article in our contemporary with some pleasure and hope more historical notes will be published in it.

* * *

The success that has attended the manifold applications of catalysis in chemical industry is fast becoming a commonplace. Yet all that has been achieved by single-reaction catalysis, as exemplified by the hydrogenation of oil and the synthesis of ammonia, important as it is, is but little compared with the vast possibilities opened up by the utilisation of preferential catalysis. This newer phase of the question has hardly yet reached industrial application, but sufficient experimental evidence is forthcoming to show its importance. Our last issue contained an article on "Preferential Oxidation in Presence of Catalysts," which provides a valuable summary of our knowledge of this fascinating subject. Special attention was devoted to the oxidation of sulphuretted hydrogen in industrial fuel-gases and to the utilisation of hydrocarbons as a source of a variety of useful products. The problems attending the purification of coal-gas are well known and the importance attaching to the partial oxidation of hydrocarbons becomes very plain when it is realised that developments in this direction may help to solve the problem of conserving our dwindling supplies of fuel oils. In publishing this article, we desired once more to direct attention to the subject, in the hope that it may stimulate further inquiry in this new and vast field of research.

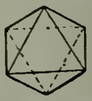
A METHOD OF REPRESENTING CO-ORDINATED COMPOUNDS

By PROF. T. M. LOWRY, F.R.S.

The diagrams used conventionally to illustrate stereoisomerism in co-ordinated compounds are by no means satisfactory. The first essential of such a diagram is that the six co-ordinated groups in compounds such as potassium cobaltinitrite, $K_3[Co.6NO_2]$, or the hexammine of cobaltic chloride, $[Co.6NH_3]Cl_3$, should be represented as occupying identically similar positions. As Werner points out, these six positions might be either the six corners of a hexagon, the six corners of a triangular prism, or the six corners of an octahedron. In the two former cases, three series of di-derivatives should exist, corresponding to the *ortho*, *meta* and *para* di-derivatives of benzene, whereas in the third case only two series of derivatives, corresponding to the *cis* and *trans* derivatives of ethylene should exist. The experimental evidence was conclusive in favour of the last method of representation and Werner's octahedron is now established on a foundation of experimental fact that is but little, if at all, inferior in strength to that on which the tetrahedral carbon atom of Le Bel and van't Hoff reposes so securely.

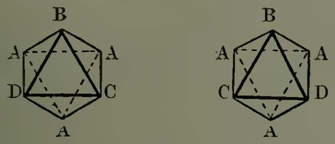
The diagrams used by Werner to represent these octahedra (consisting of a square pierced by an axis of fourfold symmetry) are, however, seriously at fault, since two of the positions appear to be distinguished sharply from the other four. On the other hand, the correct projection of an octahedron, as used in crystallography, is not easy to draw accurately; and even when this has been done, it has the disadvantage that one of the corners is hidden from view at the back of the projection.

The disadvantages of both of these systems can be avoided by making use of the fact that an octahedron resting upon one of its triangular faces has a hexagonal outline when viewed from above, *e.g.*, from a distant point on one of the axes of threefold symmetry. This hexagonal outline is easy to typewrite and easy to print. It is moreover already familiar to many who are handling chemical manuscripts from its use in the formulæ of benzene and other aromatic compounds. All that is necessary in order to convert the hexagon into an octahedron is to unite the 2 : 4 : 6 positions by three straight lines (resembling "meta" linkages) to represent the edges of the upper face of the octahedron; if desired, the outline of the lower face can also be shown by joining the 1 : 3 : 5 positions by dotted lines, thus:



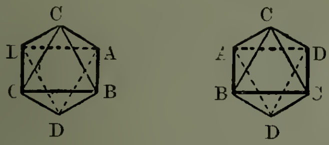
As illustrating the usefulness of this method of representing co-ordinated compounds, diagrams are given below to show the enantiomorphism of the different types of compounds to which Werner attributed molecular asymmetry.

(a) *Complex radicals of the type* $[MeA_3BCD]$



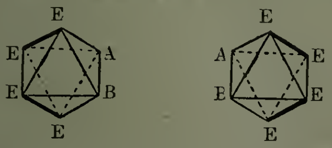
In this case enantiomorphism arises from the clockwise or counterclockwise arrangement of three different substituents, BCD, occupying one face of the octahedron.

(b) *Complex radicals of the type* $[MeABC_2D_2]$



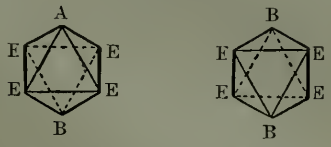
If BCD do not occupy one face of the octahedron, they must necessarily be grouped on one of the square sections which form the principal planes of symmetry. In this case, in order to produce asymmetry, the two apices on either side of this square section must be occupied by two different radicals, *e.g.*, A and B, or C and D. When viewed from one of these similar apices, *e.g.*, C, the four radicals ABCD on the square section then show *either* a clockwise *or* a counterclockwise sequence.

(c) *Complex radicals of the type* [MeAB en$_2$]

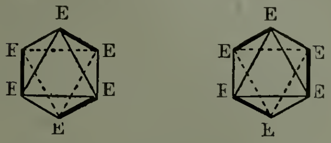


In these diagrams the bivalent radicals " en," which may be identical, are represented by the symbol E——E. Werner points out that the univalent radicals A and B can also be made identical without destroying the asymmetry of the figure; but he distinguishes this as a totally different type of asymmetry, since the octahedron can no longer be separated into two non-superposable tetrahedra. The fact that the asymmetry of co-ordinated compounds of this type persists when A and B are made identical is, however, clearly shown in the diagrams reproduced above.

Werner points out that the univalent radicals A and B or B and B in this type must occupy the *cis* position to one another, since the *trans* isomers possess a plane of symmetry. This is clearly shown in the diagrams set out below, where the removal of the univalent radicals from the " ortho " to the " para " position obviously introduces a vertical plane of symmetry into the diagrams :



(d) *Complex radicals of the type* Me en$_3$



The fact that optical activity can be produced by three identical bivalent radicals, associated with a single atom of metal, may be regarded as the final vindication of Werner's hypothesis; but some of us to whom this phenomenon is by no means new still have to think hard in order to produce a correct diagram of the two enantiomorphous forms even of a simple compound such as the cobaltioxalate, K_3 $[Co.3C_2O_4.]$ When the system of diagrams now suggested is used, this difficulty disappears completely, since the two enantiomorphous forms of the compound can be depicted as easily as the two variants of Kekulé's formula for benzene.

The two diagrams shown above have the further advantage that the existence of a threefold axis of symmetry (with 3 twofold axes of symmetry perpendicular to it) is clearly demonstrated. The thick lines representing the three bivalent radicals are therefore arranged like the blades of a propeller, but of opposite signs in the two cases. Thus, if the figure were rotated in a clockwise direction about the threefold axis, the blades would tend to drive the figure towards the observer in the first case, but away from him in the second case.

NITRE CAKE

Suggestions for its Utilisation and an Improvement in the Manufacture of Nitric Acid

By H. H. GRAY, B.Sc.

More especially during and since the War, when the production of nitre-cake reached a point never touched in the previous history of the British chemical industry, many suggestions and processes have been put forward for the utilisation of this troublesome by-product, but it was only recently that the London correspondent of an American technical journal intimated that the "nitre-cake problem was still with us."

The writer has often been amazed at the way in which chemical manufacturers can utilise materials imperfectly and yet make a profit, but nothing has ever seemed so surprising as the curious state of affairs which during the War compelled the management of one explosives factory to pay twenty-one shillings per ton for the disposal of nitre-cake. Very recently he was credibly informed that it was possible to buy nitre-cake at seven shillings per ton. In the latter case the curious thing was that the firm who sold the material was a large consumer of sulphuric acid and sodium sulphate. No doubt the ultra-commercial attitude of some people in the industry is responsible for this state of affairs, and it will be a good thing for old England when stewardship replaces profit-mongering, and when the patriotism of the battlefield is more widely recognised as being very near akin to that form of public spirit which takes pleasure in the efficient utilisation of the national resources or the securing of a contract for one's native country.

However, that day is rather far distant owing to the complexity of human nature, and it is perhaps time to proceed with the matter indicated by the heading of the article.

Being acquainted in a general way with the ease of reversibility of the reaction by which hydrochloric acid gas is generated from solid sodium chloride by the action of sulphuric acid, the writer put it to the test one day on the off-chance of devising a method for the recovery of sulphuric acid alone from the nitre-cake, and was rather astonished to notice the ease with which gaseous hydrochloric acid or concentrated hydrochloric acid solution will cause the precipitation of sodium chloride from a solution of nitre-cake or from a solution of crystallised sodium bisulphate.

The reaction $NaHSO_4+HCl \rightarrow H_2SO_4+NaCl$ is apparently very rapid, and so soon as the solubility product of the sodium and chlorine ions is attained the reaction commences. The solubilities of sodium sulphate and bisulphate together with that of gaseous hydrochloric acid in sulphuric acid are the controlling factors. If the sulphuric acid is so concentrated as to dissolve little hydrochloric acid, then the solubility product of sodium chloride is not attained, and the hydrochloric acid gas passes off and so out of the sphere of reaction. It would perhaps be a desirable addition to the discussion of this reaction in students' text-books of Inorganic Chemistry, if the fact were emphasized that it is not the volatility of the hydrochloric acid gas which causes its evolution, but the relative insolubility of the gas in sulphuric acid of concentrations exceeding 70 per cent. which allows the reversible reaction $NaCl+H_2SO_4 \rightarrow NaHSO_4+HCl$ to proceed. The same result would be obtained if the HCl took the form of insoluble crystals instead of a gas.

The first results of a rough quantitative examination of the reaction were encouraging, inasmuch as a clear saturated solution of crystalline sodium bisulphate yielded sulphuric acid of over 40% H_2SO_4 and containing less than 0·5% solid residue. The bubbling of HCl gas through a solution of nitre-cake in contact with solid nitre-cake at room temperature yielded an acid containing 60% of sulphuric acid. Thus the reaction is very promising, and seems to hold out the hope of a cyclic process in which the two reactions

[I.] $NaCl+NaHSO_4 \rightarrow Na_2SO_4+HCl$
[II.] $NaHSO_4+HCl \rightarrow NaCl+H_2SO_4$

are combined. The hydrochloric acid is seen to be in circulation, and theoretically one molecule of sodium chloride suffices for the process. The two end-products are sulphuric acid and sodium sulphate, both being eminently more useable and saleable than the inconvenient nitre-cake. There is, of course, some sodium acid sulphate contained in the sulphuric acid which is produced in contact with solid nitre-cake, but where this acid could be utilised on a large works this should not prove a fatal objection, and if the acid could be obtained in a form suitable for use on a nitric acid plant it would be no objection at all. Sodium sulphate and crude sulphuric acid are quoted in the current issue of *Chemistry and Industry* at £5 and £3 10s. per ton respectively, and this seems to offer a satisfactory margin over the 7s. per ton obtained by the firm mentioned above, and to be more satisfactory than the general nuisance of nitre-cake accumulations.

The results obtained above, whilst of great promise, are only preliminary, and the writer has no doubt that a satisfactory scientific examination of the three-component system represented by equation II. would yield interesting results. For example, the nature of the reaction indicates the usefulness of increased pressure, and results might be obtainable which would justify the overcoming of the technical difficulties which would probably stand in the way of using hydrochloric acid gas under pressure. Undoubtedly the use of hydrochloric acid gas under pressure would increase the concentration of the resultant sulphuric acid, but both laboratory and large scale investigations would be necessary before the best temperature and pressure could be ascertained. The margin in price between the possible products and the almost unsaleable nitre-cake would seem, in the writer's opinion, to justify quite a considerable outlay in experimental work, seeing that his laboratory results have been so satisfactory.

PAPER *

By J. HUEBNER, M.Sc.

Paper is a fabric made by depositing fibres in a very finely divided state, from suspension in water, by the means of a sieve. Paper, although a comparatively new invention, was manufactured in a crude state so far back as 123 B.C. by the Chinese. Prior to that any material which possessed a suitable surface for carving or writing upon was used for writing purposes—*e.g.*, metal, wood, clay, skins of animals, etc. One of the earliest writing materials used was parchment, which was prepared from skins of animals. Another one, the papyrus of the Egyptians, was used in 3000 B.C.

The invention of paper travelled first from China to Corea and Japan, and was then brought by the Arabs to Egypt. From here it developed further along the north coast of Africa, whence it ultimately reached Spain and Italy. Paper-making may then be traced to other European countries, and the first paper mill in this country was established towards the end of the fifteenth century. We find records of another paper mill during the reign of Elizabeth, and in 1770 the well-known mills at Maidstone were established by Whatman.

Vegetable fibres form the chief raw materials used in the manufacture of paper. Animal and mineral fibres are but rarely used; the former in the manufacture of some blotting and calender bowl papers, the latter for fireproof papers and boards. The vegetable fibres may be divided into two classes—rag fibres and rag-substitute fibres. The rag fibres are linen, cotton and hemp, whilst all the other vegetable fibres, such as esparto, straw, wood fibres, etc., are rag-substitute fibres. Until about 1850 papers were made exclusively of rags, although attempts had been made by Koops in 1800 to make paper from straw, wood and old paper.

In 1840 mechanical wood pulp was first made by a hand loom weaver in Saxony. From that time onwards wood fibres have formed one of the principal raw materials for the manufacture of paper. It should be clearly understood that there are, however, two distinct types of wood pulp used :—(1) Mechanical wood pulp, which is prepared by disintegrating wood (chiefly pine) by mechanical means only: this pulp consists chiefly of ligno-cellulose; and (2) chemical wood pulp, or wood cellulose, which is prepared by boiling wood either with caustic soda, with caustic soda and sodium sulphide or with bi-sulphites. The product obtained, if properly prepared, therefore consists of pure cellulose.

Whilst the durability of paper made from mechanical wood pulp is doubtful, there is no reason to assume that paper made from wood cellulose should be inferior to rag paper. The first process through which the fibrous raw material has to pass in the manufacture is that of boiling with alkaline liquids. This is followed by bleaching. In order to produce a material suitable for converting into paper it is now necessary to disintegrate the fibres. Prior to 1700 this was achieved by hammering or beating, a process which is still carried out in Japan at the present time.

About 1700 a Dutchman invented a rag engine or "Hollander," in which the fibres are disintegrated between metal knives fixed to a revolving cylinder and similar knives placed below the cylinder in what is known as the bed-plate. The result of the disintegration by the two methods differs considerably. In the slow beating process the fibres are not only reduced in length but they are actually split lengthways into fibrillæ, which interlace or felt readily, and therefore produce a paper of considerable strength. In the more modern process, which is more rapid, the fibres are apt to be cut or torn, with the result that papers made from them are as a rule weaker. Only by very careful treatment in the rag engine is it possible to avoid this difficulty and to convert the fibres partly into fibrillæ. The beating of the paper pulp is one of the most important operations in the manufacture of paper, because the properties of the finished sheet are very considerably influenced by the beating.

Prolonged beating produces "hydration" of the cellulose, with the result that the fibres become gelatinous, and the sheet of paper becomes more or less transparent. This property of the cellulose is made use of in the manufacture of "imitation parchment," or "grease-proof" paper. Such paper is highly transparent, and when a lighted match is placed underneath it becomes blistered.

The beaten fibres are finally strained in order to eliminate fibre bundles and impurities, and the pulp is now ready for the manufacture of paper.

The discovery of chlorine, and its application to the bleaching of cotton rags used in the manufacture of paper, took place towards the end of the eighteenth century. Without doubt, the greatest invention was that of the paper-making machine in 1797. Although the original patent was taken out by Robert, a Frenchman, the first paper machine was completed by the English engineer, Bryan Donkin, in 1803. In connection with this the name of Fourdrinier, a firm of stationers in London, who supplied the necessary money for the experiments, should be mentioned. Although this invention has proved of such enormous benefit to the whole world, the Fourdriniers did not only not derive any benefit from the invention, but lost everything they possessed. The working of the Fourdrinier machine was such that there was a difference between paper made on this machine and that made by hand. The tensile strain of the former is always greater in the direction in which the paper has passed over the machine than in the cross way ; whilst that of hand-made paper is practically uniform in both directions.

---

* Abstract of a paper read before the Manchester College of Technology, Evening Students' Chemical Society.

Paper made from the pure fibres is always absorbent, like blotting paper or filter paper. In order to make it suitable for writing and printing purposes, it is necessary to apply water-repellent substances, that is, to size the paper. Two methods of sizing are commonly practised. In the first, resin soap is added to the paper pulp whilst in the beater, and by then adding aluminium sulphate or alum, free resin is deposited on the fibres, which produces the necessary water repellency. This method of sizing is known as engine-sizing. In the second method of sizing, the absorbent sheet of paper, known as water leaf, is passed through a solution of gelatin, and is then dried. This method is known as tub-sizing. Hand-made papers are invariably tub-sized, whilst machine-made papers may be either engine-sized or tub-sized, or both engine and tub-sized.

The minute disintegration of the fibres played a very important part in dyeing of paper pulp. They absorb most of the dyestuffs more readily and they hold them more firmly than the fibres in the state in which they are used in spinning. Thus a number of acid dyeing dyestuffs which have little or no affinity for vegetable fibres can be used in dyeing paper pulp, and acid and basic dyestuffs can be used in combination. Alum and aluminium sulphate are employed as universal mordants, and the resin used in engine sizing also assists in fixing the dyestuffs on the fibres.

It was too early to express a definite view on the advantages and disadvantages connected with the uses of rubber latex in the manufacture of paper. It should be borne in mind that rubber was not a water-repellent agent like resin, but that it was a water-proofing agent. The question of price would no doubt play a *rôle* in the manufacture of some papers, but the product will probably find application in the manufacture of certain papers.

As regards the waste liquors from esparto boiling and from wood pulp manufacture, in which caustic soda was used, from these the soda was invariably recovered. Waste liquors from sulphate-cellulose manufacture were evaporated and treated with sodium sulphate to produce the sodium sulphide used in a subsequent boiling. Many uses have been suggested for waste liquors from sulphite mills—for instance, in the sizing of paper and in the manufacture of alcohol.

Wool was not used in the manufacture of paper. The particular objection to the use of wool fibres was their high elasticity, which resulted in a tendency to change their position during the drying of the paper. Some of the principal paper-making qualities of fibres were their fineness, non-elasticity and strength.

THE POSITION OF THE NITROGEN INDUSTRY IN FRANCE

By MAURICE DESCHIENS

The problem of the manufacture of synthetic ammonia, so vital for every nation, has recently formed the subject of an important discussion in France. On February 6 and 8 the Chamber of Deputies approved the agreement made on November 11, 1919, by M. Loucheur, representing the French Government, and the Badische Anilin und Soda Fabrik, the owners of the Haber process. Under this agreement France would not only acquire the right of exploiting the Haber process, but would be supplied by the B.A.S.F. with all information and data necessary to operate the processes employed in the works at Oppau and Merseburg for the production of synthetic ammonia, and its transformation into sulphate and nitrate. The agreement applies to a works capable of fixing 100 metric tons of nitrogen in the form of ammonia solution every 24 hours. For this concession, the French State would pay 5,000,000 francs, part to be paid at the moment when the agreement is ratified and the remainder when the factory has produced a minimum of 20 tons of fixed nitrogen per day in the form of ammonia solution during 15 consecutive days. For each kg. of nitrogen fixed, the B.A.S.F. would receive a royalty varying between 2 and 4 per cent. of the price of the kg. of nitrogen, but only after production had reached at least 30 tons of fixed nitrogen per day. The concession has a duration of 15 years, and the French State acquires the right to cede it to a public company, and to the most favourable terms if the B.A.S.F. makes other and similar contracts.

Before the war the annual consumption of combined nitrogen in France amounted to 73,000 metric tons, of which 90 per cent. was in the form of sodium nitrate (45,000 tons of nitrogen) and ammonium sulphate (100,000 tons of nitrogen). The French production, however, totalled only 19,000 t. of combined nitrogen (15,000t. in the form of ammonium sulphate, 1750 t. as cyanamide and calcium nitrate, and 2250 t. as organic manure). It was therefore necessary to import 54,000 t. of combined nitrogen, mainly in the form of nitrate of soda and sulphate of ammonia, the total value of the import then being 83 million francs, or over 248 million francs at present rates. Production still remains at about 19,000 tons per annum, whereas the agricultural consumption alone has increased to roughly 110,000 tons. It is true that a clause in the Peace Treaty required Germany to furnish 30,000 tons of combined nitrogen as reparation, but the deliveries are no longer made.

Many processes are available which could be utilised to compensate for this deficiency. Amongst them may be mentioned the processes of Birkeland & Eyde, Häusser, Haber, Claude

Casale (purchased by the Cie. d'Alais et de la Camargue), the Synthetic Ammonia & Nitrates Co., Ltd., the General Chemical Co., Matignon and Fréjacques (transformation of ammonium into urea), Bücher (cyanamide), Serpek (nitride) and the cyanamide process. Discrimination between these various processes is difficult, and for this reason the French Government asked the Académie des Sciences in February, 1921, to form a commission under the presidency of M. Théophile Schloesing to examine the question and to report whether there was any process for the manufacture of synthetic ammonia and of the hydrogen required for that purpose which worked satisfactorily and produced ammonia more cheaply than the Haber process. The report was kept secret, but sufficient is known of its contents to make it possible to state that the conclusion was that the Claude and Haber processes then offered more or less equal advantages, except that the Claude process was more economic when coke-oven hydrogen was used.

The French Government then drew up the Bill, which after revision by a committee of the Chamber of Deputies gave rise to the agreement which has just been adopted, but still awaits the approval of the Senate. By this Bill the Government would be authorised to establish a company to utilise the national powder factory at Toulouse and its plant for the annual rental of 500,000 francs and a share in the profits. The company would have a capital of 50,000,000 francs divided into 500,000 shares of 100 francs each, of which 300,000 would be retained by the State, 50,000 allocated to Agricultural Associations, 20,000 to Chambers of Commerce, 30,000 to Associations of Chemical Manufacturers, 50,000 to Workers' Associations and Co-operative Societies, and 50,000 reserved for public subscription. Any shares not subscribed by these various groups or the public would be taken up by the State. The Company would be administered by a board of 20 members, including 8 nominated by the shareholders, and 14 nominated by the Government, including 3 representing Agricultural Associations, 2 specialists on nitrogen fixation, 3 representing the staff of the company, the remainder representing various public bodies and Ministries.

An annual production of 36,000 tons of fixed nitrogen would be aimed at, and the company would have the right to utilise any process for that purpose, whether of French or foreign origin. If it was found impossible to form a company, the Service des Poudres would carry out the project at Toulouse.

This agreement has naturally given rise to most lively discussion, and the supporters of the various methods of nitrogen fixation have explained the advantages of their processes in numerous lectures and publications. It still, however, remains difficult to express any opinion on the respective values of the different processes until they have been tried on a large scale over a considerable period. It should be noted that since the report of the committee was issued certain of the processes have been greatly improved and new ones have been brought out. Utilisation of the arc processes would be difficult in France, with the present conditions of water-power, because they require 60 kilowatt-hrs. per kg. of nitrogen fixed, whereas the manufacture of cyanamide requires only 17 to 18 kilowatt-hrs. At the Montereau factory the Claude process is now producing 5 tons of ammonia per day regularly and easily. This process is therefore satisfactory from the industrial point of view, and a large plant to utilise coke-oven hydrogen is already working at Béthune. The advantages of the Claude process are fairly well known, but it may be remarked that per gram of catalyst the Claude process yields 6 grams of ammonia against 0·5 produced by the Haber process. The gas has to be passed only four times over the catalyst to produce the same effect as the Haber process in 15 days. In addition, the Claude process can be utilised wherever coke-ovens are present, and the plant is very much smaller and cheaper to install. It may be observed that, according to the report by the Director of the Service des Poudres to the Finance Committee of the Chamber of Deputies, the Casale process has given extraordinary results. Improvements, however, are being made in all the processes for fixing nitrogen, and it is to be hoped that no process will be unduly favoured, so that actual commercial competition will finally decide which process or processes are to remain.

CHEMISTRY AND THE SAFETY OF THE WORKERS

Industrial Hygiene is of interest to all readers of this journal and is becoming a subject of considerable importance. Last week we gave a brief account of the admirable work of Mr. G. E. Duckering, the Director of the Government wool-disinfecting station at Liverpool, and next week we hope to publish a notice of the paper recently read by Dr. T. M. Legge before the London Section of the Society. The Home Office has during the last twenty years reduced the amount of industrial disease and deaths from it to an extent which is quite inadequately recognised, and it is to be warmly congratulated on having such men as Dr. Legge and Mr. Duckering to advise it. Among the experts their reputation is very high, and it should be equally high among all those who are interested in the application of science to the benefit of mankind.

In asking works chemists to watch for the earliest indications of danger from injurious substances, and in inviting the co-operation of the works chemist in Industrial Hygiene, Dr. Legge has performed a useful service.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

THE JOINT MEETING of the Manchester and Liverpool Sections of the Society, held in Manchester last week, was a great success. It began well at the luncheon, when nearly 70 members were present, and I thought the after-luncheon speeches served to give the right note to the day's proceedings. I was particularly interested in the few words which Sir William Kay, the Chairman of the Gas Committee of the Manchester Corporation, had to say in reply to the toast of his health. Evidently he has devoted himself whole-heartedly to the task of giving Manchester a first-rate supply of gas. The President was also in good form, and I believe his devotion to the work of the Society is a valuable stimulus not only to the officials but to the rank and file.

THE TRAM WAITING at the door of the Hotel was a powerful inducement to the speakers not to deliver long speeches, and we were away to visit the gas works very shortly after the time arranged. The works proved well worth braving the elements, which were not too kind, and everyone was enthusiastic in praise of Sir William Kay, who had arranged the visit. The next official appointment was not until 7 o'clock, and the interval was taken up by little informal gatherings, at the Textile Institute, the Engineers' Club and elsewhere, which I thought were not only very pleasant but likely to prove most stimulating to the work of the Society. Indeed, from the commencement of the day's proceedings until the last stragglers caught the last train at midnight the hospitality of the Chairman (Dr. Ardern) and the Secretary (Mr. Guy Radcliffe) of the Manchester Section never ceased. The whole of the arrangements worked most smoothly, and I hope we shall have more of these joint meetings.

DR. LEVINSTEIN'S PAPER on "The Progress of Chemical Industry in Great Britain since 1914," was listened to with the greatest attention. He spoke for an hour and a quarter in such an interesting way that the audience seemed oblivious to the flight of time. In an historical sketch of this kind some of the facts are necessarily known to those who listen, but there were various comments which the speaker made as he went along which I thought very illuminating. He contrasted the panic in the textile industry in 1914, when the supply of German dyes was cut off, with the entire absence of any such panic to-day when the French are in the Ruhr. When one thinks about it this seems one of the most striking testimonials to the progress of the British Dyestuff Industry which could be imagined. A second point was the extent to which our Foreign Office might have been handicapped in dealing with the present international situation if they had to have at the back of their minds the dependence of this country on the dyestuff factories on the Rhine. Fortunately this additional complication no longer exists.

SIR MILTON SHARP the other day gave to the shareholders of the Bradford Dyers Association one of those statesman like addresses to which we are accustomed. Incidentally, I rather fancy he supplied the key to a little problem which has troubled me for a long time. We have been told recently on quite good authority that the British makers have now brought the average price of their dyestuffs down to three times the pre-war German price. On equally good authority, Sir Milton Sharp to wit, we find that the Bradford Dyers Association basis price of 100 in 1913 was 424 in 1922. Superficially there is something wrong here, but not really, for Sir Milton also tells us that the general demand to-day is for superior qualities in dyed goods and that his firm is now using dyes of a superior quality to those in general use pre-war. Further, he tells us that his firm are using 77·66 per cent. of British made colours. So that's that!

THE BRITISH INDUSTRIES FAIR is past and over for the year. I talked with some of the exhibitors and was astonished to find them protesting vigorously at the suggestion that the Fair should not be held next year owing to the arrangements for the exhibition at Wembley. However, it has now been definitely decided that the Fair will be held in 1924. On the whole, the Fair reflected very faithfully the general upward trend of chemical trade, and the majority of the exhibitors in the Chemical Hall were quite satisfied with the business done. Right up to the close the Fair was receiving many distinguished visitors. Dr. Herbert Levinstein spent some hours in examining the exhibits, and another visitor who took considerable pains to make himself acquainted with what was being shown was the Prime Warden of the Worshipful Company of Dyers. Drawing closer together day by day, the various organisations, scientific and commercial, which are connected with Chemistry seem to be learning the lesson of co-operation. I am told that a sub-committee of the Royal Society met a committee of representatives of other learned, quasi-learned and industrial bodies only this week. If it be true this is good news.

FORTHCOMING EVENTS

Mar. 16. Society of Chemical Industry, *Liverpool Section*, Muspratt Lecture Theatre, the University, Liverpool, at 6 p.m. "Some Aspects of Fractional Distillation," by A. Brittain and C. Elliott.

NEWS FROM THE SECTIONS

OTTAWA SECTION

The function of chemistry in the service of the State is of increasing importance, especially in a young country like Canada, with her great abundance of undeveloped natural resources. The following series of papers, read before the Ottawa Section, briefly set forth the main functions of the chemist in the Departments of the Canadian Government.

Chemistry in the Department of Mines

The Department of Mines was established by the Geology and Mines Act, 1907, which divided the Geological Survey, founded in 1843, into two branches, the Geological Survey and the Mines Branch. The Geological Survey is concerned with the study of the geology and mineralogy of Canada, whereas the Mines Branch is concerned with the investigation and economic development of the mineral resources. It follows therefore that the majority of chemists will be employed by the Mines Branch, which comprises five divisions, viz.: (1) Mineral Resources; (2) Ore Dressing and Metallurgical; (3) Fuels and Fuel Testing; (4) Ceramic and Road Material; (5) Chemical. Each division has chemists on its staff.

The Mineral Resources Division collects detailed information and statistics on mineral deposits, mining operations and market conditions in Canada, and carries out investigations on various phases of the mineral industry. Examples of such work at present in progress are: (*a*) The development of chemical and metallurgical industries in Canada; (*b*) molybdenum, its occurrences, production and uses; (*c*) mineral pigments in Eastern Canada; (*d*) sodium-sulphate deposits of Saskatchewan and Alberta; (*e*) bituminous sands of Northern Alberta; etc.

The Ore Dressing and Metallurgical Division is concerned chiefly with special problems of the treatment of the Canadian ores. During 1921 tests were made on the treatment of gold ores from Manitoba, and on the concentration of low-grade copper and nickel-copper ores. Other subjects of investigation are the recovery of metals of the platinum group from placer concentrates and from certain copper-nickel ores, the use of Canadian-made flotation reagents, the production of electrolytic iron from pyrites and pyrrhotite, and the removal of impurities from coal by washing and flotation. The chemical staff of this division consists of five chemists and assistants, and their work varies from the simplest of qualitative analysis to complete quantitative mineral separations.

The Fuels and Fuel Testing Division has the largest chemical staff of any in the division, comprising a chief, four chemists and two assistants, besides the necessary laboratory help. Their work is in part analytical, such as is required in testing boilers, producer-gas plants, etc. The coals of Canada are being systematically analysed; lubricating oils and gasoline samples are examined; but much of the work is of an investigatory nature. The following problems are illustrative :—The determination of the physical constants of coals; the development of a standard method for testing oil shales; tests of processes for retorting oil shales; the carbonisation of lignite and peat.

The Ceramics and Road Materials Division has charge of the development and investigation of Canadian materials used in ceramic industries and in road-making. There is no chemist as yet on the staff of the division, and most of the chemical work required is done by the chemical division.

In the Chemical Division the staff consists of a chief, three chemists, two assistant chemists and laboratory assistants. The work carried on is very varied, many samples of rocks, minerals, alloys, waters and gases being sent in for identification or for analysis. In 1921, 754 samples were dealt with. Special investigations also receive attention. At present the peculiar properties of the colloidal clay, bentonite, are being studied. Another problem is the use of natural gas as a raw material for the production of industrial chemicals. The air-drying of peat has been under study for some years.

The Explosives Branch was established by the Explosives Act of 1914, and its functions are to regulate the manufacture, importation and use of explosives in Canada. Its duties range from the investigation of accidents due to explosives, the inspection and licensing of explosive plants, and the examination of all types of explosives.

Work done by the *Mineralogical Division of the Geological Survey* comprises the study of rocks and the chemical analysis of new minerals. The methods of analyses employed are based on those of Hillebrand, supplemented by special methods developed in the laboratory.

The attention of the staffs of these laboratories is often also given to problems of a chemical or physical nature submitted by other Government Departments.

Laboratories and equipment.—The five laboratories in which chemical work is carried out in the Department of Mines, are well equipped with the most modern types of chemical apparatus, in addition to physico-chemical apparatus, a micrographic outfit, and an X-ray apparatus. There are four branch chemical libraries apart from the main departmental library. Every facility is provided for the manufacture and repair of special and ordinary apparatus. The number of chemists employed in the Department of Mines has risen from three in 1910 to twenty in 1923, and with the increasing development of Canada's valuable mineral resources the number must rapidly grow. The salary paid is not sufficient, but it enables a man to live fairly comfortably. The work is interesting and there is every opportunity for original investigation and publication of results.

Chemistry in the Department of Customs and Excise

The chemist plays an important part in the administration and control of the tariff laws and regulations. The chemical laboratories of the Department of Customs and Excise, now two in number, were among the earliest to be established in Ottawa. At present the staff consists of six chemists and several laboratory assistants. The work required for the enforcement of the Excise regulations chiefly requires the determination of alcohols, the examination and control of denaturants and the standardisation and supervision of hydrometers. Much control work on raw sugars and molasses is carried out. Many technical matters concerning Excise regulations requiring chemical knowledge are also submitted for opinions. The work required by the Tariff regulations is exceedingly varied and requires considerable experience and encyclopædic knowledge of the composition and properties of drugs and manufactured products of all kinds, besides close acquaintance with the many Customs regulations. In November last, the two laboratories examined a total of 250 samples, which ranged from drugs and medicines to dyes, tar oils, cements, alloys, soap and washing powders, ores, fish offal and metallurgical products. Besides such analytical work the Chief Chemist is often called upon for opinions on technical matters that arise in formulating and enforcing the Customs' regulations.

Division of Chemistry, Dominion Experimental Farms

The establishment of the Division of Chemistry coincided with that of the Dominion Experimental Farm System, of which it is an integral part. Its functions and duties have been interpreted as including two main lines of work :—(1) the solution of agricultural problems requiring the aid of chemistry and (2) chemical service, *i.e.*, educational and advisory work for the man on the land. In addition the division has undertaken analytical and research work for the Department of Agriculture and other Government Departments.

The types of investigation required range from the complete chemical and physical analysis of soils, fertilisers, the investigation of nitrogen-fixation in leguminous plants, research on the effect of climate and soil on the crop, control work on sugar-beet and forage crops, feeding stuffs, and the testing of insecticides, fungicides, to work in connexion with the administration of the Meat and Canned Foods Act, and the Oleomargarine Act. The results of the work are issued from time to time in the form of bulletins, which, like the Annual Report, are of wide interest to the farming community. The division started in 1887 with one man and a small room, but to-day the staff numbers 20 and includes 15 chemists. The chemical building housing the division contains six laboratories; an extension is planned which will afford much needed room for expansion.

Laboratory for Testing Materials, Department of Public Works

This laboratory was established about 1890 for the purpose of testing all the cement used by the Department of Public Works. Later it was enlarged to include the testing of concrete aggregates and concrete mixes, and still later, tiles, bricks, reinforcing materials and limes and plasters were included in the work. During the last eight or nine years the laboratory has tested all structural and other materials purchased by the Department. The laboratory is now purely departmental, and no work is carried on for other departments or outside interests. The staff of this laboratory has increased from one, at its inception, to nine permanent employees and two temporary employees during the summer months.

Chemistry in the Department of Health Laboratories

The Canadian Government has for many years maintained a well-equipped laboratory staffed with chemists and bacteriologists who give their whole time to the detection of adulteration and the education of the public in the intelligent purchase of food and drugs. The laboratory, situated at Ottawa, was established in 1885 under the control of the Inland Revenue Department, but is now controlled by the Department of Health, and has well-equipped branches located at Halifax, Winnipeg and Vancouver. The central laboratory has normally a staff of about 10 analysts, and in each branch there is a senior analyst and one assistant. In order that the work of control may be carried out more effectively, the Dominion has been subdivided into 25 districts, in each of which there is a resident inspector, who forwards suspected samples to the nearest departmental laboratory for examination. In order that adulteration of a sample may be established, it is necessary to know the chemical characteristics of genuine commercial samples of that product and its limits of variability. For this reason, examination is constantly being carried out of large numbers of samples of known authenticity, and when sufficient data have accumulated a tentative standard is drawn up. This is submitted to interested parties as well as an advisory board of three of the leading analysts of the country. When approved, the standard is legalised, being promulgated by Order in Council.

There is hardly a Department which does not find it necessary at intervals to obtain the assistance of these laboratories in the elucidation of their chemical problems. In spite of the handicap imposed by the inadequate technical staff, during the last fiscal year over 5400 samples were examined, many requiring a number of long and difficult determinations, and 225 prosecutions were entered for violation of the Food and Drugs Act alone. In addition to the work briefly outlined above, much educative work has been carried out both by correspondence and by means of the publication of bulletins, of which 440 have been issued to date. The officials of these laboratories are always glad to furnish interested parties with the latest information regarding the composition and value of the foods and drugs on the market. Providing also that the work required does not conflict with the interests of commercial analysts they are also willing to assist manufacturers with their chemical problems.

A meeting was held in the University Club on February 7, Mr. Hambly in the chair. The chairman asked for references to current literature, and Dr. Macintyre gave a very interesting outline of the discovery of the new element hafnium by Profs. Coster and Hevesy, as announced in *Nature* and by Dr. Scott at a meeting of the London Chemical Society. He showed the association of the new element with the titanium-zirconium group, and suggested that it would be very interesting to Canadians if the black titaniferous sands of the Lower St. Lawrence, near the Moisie River, were found to contain this new element in an appreciable percentage. In announcing the subject of the evening's discussion, Mr. Hambly said that much of the recent activities in chemical research had to do directly with life problems. He mentioned the joint meeting in London, in January, of the London Section of this Society and the Biochemical Society. In referring to a review of Dr. MacCallum's book on the " Newer Knowledge of Nutrition," he said that some of the most interesting parts of the book were devoted to the thesis that various states of illness, both mental and physical, were to be attributed to faulty diet and not to disease.

Mr. G. Ennis Smith, Biochemist of the Research Laboratory, Hull, then gave an interesting talk on " Biochemistry in Relation to the Rearing and Nutrition of the Silver-black Fox". He spoke of the difficulties and problems that were harassing the fox industry and urged the necessity of careful attention to feeding, particularly during the time of breeding. The most favourable results were obtained by feeding a maintenance ration during this period. Over-feeding caused the arrest of the development of the young pups. A discussion followed in which Dr. Shutt, Mr. Hambly, Dr. Macintyre, Mr. Ellsworth and Mr. Hossack took part.

Mr. J. H. Harris, M.P. (East York), referred to his long association with the Society of Chemical Industry, and expressed his pleasure at being present at the meeting. He urged the necessity for putting before the public the results of chemical activities in a greater measure than is now done.

MONTREAL SECTION

An extra meeting was held on January 8, 1923, in order to hear a paper by Dr. Abrams, who is the professor in charge of the Structural Materials Research Laboratory, Lewis Institute, Chicago. Dr. Abrams' paper, "Scientific Methods of Making Concrete," was on a subject of such broad interest that the co-operation of the Engineering Institute of Canada resulted in an unusually large attendance.

Special stress was laid on the importance of correct proportion of water, sufficient to produce proper plasticity only yielding the best result. Unsatisfactory jobs were invariably traced to the use of too much water, added with a view to obtaining a mix which would flow very easily. Charts were used to show the increase in strength of concrete due to maturation, and this increase has been demonstrated to progress steadily for at least five years, a period during which the test samples had been kept in a moist atmosphere. It was also shown that, should maturation be arrested by cold or dryness, the process would be resumed if moist conditions were again encountered, and that the maximum strength would be eventually reached, though so far the actual period had not been determined, the tests having been conducted continuously during a period of only five years. The effects of the presence of calcium hydroxide, calcium chloride, and tannic acid were shown graphically, the weakening action caused by the last-named being very marked.

The February meeting was held at the Queen's Hotel on February 19, Mr. Frank W. Horner, Vice-Chairman, presiding. The responsible committee reported on their award of the prize of $50 for the best essay by a senior student of McGill University on his summer vacation work in applied chemistry. Mr. Monro, who was adjudged to have deserved this distinction, was congratulated, not only on the work done, but on the concise and systematic essay presented in very excellent language. In elaborating the reasons which influenced judges in making awards, Mr. Hazen laid special stress on the importance of using good English, and of presenting the facts clearly, with careful illustrations that are easily comprehended and tell their story accurately. Mr. Monro will read his paper at the April meeting.

"Chemical Patents" was the subject of the paper presented by A. E. MacRae, B.Sc., F.C.I.C., Chief Examiner at the Patent Office, Ottawa. Mr. MacRae showed that the inventing chemist was faced with two alternatives for the protection of his inventions, viz., (1) to keep his processes and methods secret, or (2) to protect them by patents. Of these, the latter was by far the more efficacious, since with modern methods secrecy was practically impossible. On the other hand, it was difficult to get patents that really protected, and even more difficult to prevent infringements of such patents. One of the difficulties experienced at the Ottawa Patent Office was the fact that the growth of industrial requirements and the general trend of inventive genius and research to meet these needs had led to similar inventions being produced simultaneously throughout the world. The result was, sometimes not only conflicting claims on the part of inventors working along the same lines independently in different places, but also that unless the man who hit on the most valuable invention did not patent it he ran the risk of losing the rewards of his research and inventive genius. Patents were indispensable, and to ensure proper utilisation, inventions must be properly protected by patents, because without such safeguards there would be little incentive for independent scientific research and invention.

Mr. Macrae proceeded to show the historical development of the law of patents, which, he said, was simply a contract between the nation and the individual. Under this contract the inventor had to disclose to the public the effect of his intellectual work. By so doing he stimulated invention, research and enterprise, while in return he was guaranteed a monopoly for a certain period (in Canada 18 years) of the benefit accruing from his inventive genius and research.

GLASGOW SECTION

Mr. W. E. Moodie presided over the meeting held at the Institute of Engineers and Shipbuilders on March 2, and Prof. J. H. Andrew, D.Sc., read a paper on "The Solid State of Matter."

Prof. Andrew showed how the metallurgist could help the engineer by studying the physical properties of alloys in relation to the physical and chemical properties of their constituent elements. It should be possible ultimately to calculate the properties of any kind of steel from its chemical composition and the conditions of its formation. New theories of the structure of matter and of the union of atoms by means of their electrons were throwing light upon the nature of the solid state, and particularly on the properties of metallic alloys used in engineering.

It was shown, for example, that the engineering industry, as regards ferrous metals, depended upon the fact that iron exists in two forms according to its temperature, and that the high-temperature form dissolves carbon whilst the low-temperature form does not. It was also pointed out that steel containing 13 per cent. of chromium was rustless because the atoms of iron within it were surrounded by atoms of inert chromium, and so protected from atmospheric oxidation. Thus emphasis was laid on the importance of the study of metallurgy on physico-chemical lines, because in that direction lay the possibility of development in the industrial application of metals.

MEETINGS OF OTHER SOCIETIES

SOCIETY OF GLASS TECHNOLOGY

Prof. W. E. S. Turner, D.Sc., presided at the meeting held in Armstrong College, Newcastle-upon-Tyne, on February 21.

The first paper was entitled "Organising for Production from Pot Furnaces," by W. W. Warren, A.M.I.C.E., A.M.I.E.E. The paper was based on experience gained at the Lemington Works, where electric-lamp bulbs were made from pot furnaces. Bulb manufacture magnified possible sources of waste—waste of time, waste of metal—and demanded a close control of both system and workmanship. Comparing actual practice at Lemington with that of 1918, when the output of hand-made bulbs was approximately the same in number and weight, only 20 pots were now in commission, as against 70 in 1918. This intensification of production had effected a great saving of coal, pots, and labour. The furnaces that had been shut down were direct coal-fired furnaces. In 1918, four men worked at a pot, where there were now six; and the time-table system of founding by night and working by day was not so perfect as it was now. Production on a satisfactory basis could never be achieved unless the furnace permitted rapid melting, perfect and elastic control of temperature, and uniform distribution of heat. Time occupied in working-out pots, cooling-off pots beyond the "plaining stage," and charging with batch and cullet, should be regarded as operations, albeit necessary, which lowered melting efficiency. For most purposes circular gas furnaces, either regenerative or recuperative, were preferable to those of rectangular shape. The semi-circular or "D" shaped furnaces developed at Lemington, although not efficient in fuel consumption, had an appreciable range of temperature control above that necessary for melting, and rose quickly when set away for the found. The heat stored in the wall representing the straight line of the "D" was considerable and made for uniform heat conditions. The maximum temperature of the furnaces when using covered pots was 1500° C., and when using open pots 1400° C. During the working period the temperature was lowered to 1100° C. inside the pot. Among the advantages of working to a time table, when founding and working during definite periods, were:—(*a*) A responsibility devolved on the producer and furnace men to have metal ready in time for their co-workers; (*b*) mixing, filling pots, and all labour subsidiary to glass-making worked smoothly in an appointed groove. The importance of checking the output of pots should be realised, and figures taken out daily to inform the management of variations in pot efficiency. Reduction of costs when idle plant was brought into commission, thereby increasing production, needed no comment; but the similar effect as the result of operating more efficient plant was striking.

In view of the practical demonstration at Lemington of the possibility of ladling either lead or lime-soda glasses from pots into a tank, and the successful operation of the Westlake bulb-blowing machine in conjunction therewith, it would appear reasonable to expect to derive the full advantages of such practice if used in producing hand-made ware. The disadvantages were those attached to shift work and to ladling glass. The tank would probably throw small stones, and blisters might be prevalent. There would be the further disadvantage common to all large units of plant when under repair, viz., temporary cessation of a large output. Further, the large unit was not so elastic in coping with a variable demand. The first step in any scheme devised for intensifying production was to enlist the co-operation of the glass-blower or the worker in glass. Propaganda and foremen's meetings maintained enthusiasm and fostered the progressive spirit. Informal talks with the men's committee rarely failed to convince that foreign competitors' methods and prices were a challenge to business sport. But if there were rewards at the end of the production programme, the men must share.

During the forenoon, a party of members visited the Glass Works at Lemington.

Two papers on "The Effect of Boric Oxide on the Melting and Working of Glass," by F. W. Hodkin, B.Sc., and Prof. W. E. S. Turner, D.Sc., and "Some Physical Properties of Boric Oxide-Containing Glasses," by Violet Dimbleby, B.Sc., S. English, M.Sc., and Prof. W. E. S. Turner, D.Sc., were presented together by Prof. Turner. Although boric oxide had been used as a constituent of glass for at least a century, it assumed much greater importance owing to the researches of German workers at Jena about forty years ago. In the last few years borosilicate glasses had been used to an increasing degree, the new British chemical glass, the American Pyrex glass for chemical ware and cooking ware, and various forms of illuminating glasses, all containing it. Experience showed that the usefulness of boric oxide was limited, and further experiments on heat-resisting glasses must lie in other directions than the employment of boric oxide.

ROYAL SOCIETY OF ARTS

A paper on "Heat Resisting Glasses" was read by Prof. W. E. S. Turner at the meeting held on February 28.

The first cause of the tendency of glass to fracture on heating is its low thermal conductivity, but this alone does not entirely account for the fracture. In practice the thermal endurance, *i.e.*, the power of a glass to withstand thermal shock, might be determined by heating it to varying temperatures and determining the comparative tendency to fracture when dropped suddenly into cold water.

So far attempts to improve the heat-resisting power of glass have been either in the direction of increasing the mechanical strength by processes of hardening or of diminishing the co-efficient of expansion. In de la Bastie's method of hardening glass, introduced about 1874, the glass was heated up to the stage of softening and then placed in a bath of hot oil made up of a mixture of oils, wax, tallow, resin, etc. Experiments were made in this country to apply the new process, but without commercial success.

Of other systems of toughening glass, probably that of Siemens is best known, the process apparently being to subject the articles to mechanical pressure inside metal or fireclay moulds. The most successful method of providing mechanical strength to resist thermal shock was that of Schott (1892), who showed that glasses of different co-efficients of expansion could be united when gathered on the blowpipe in successive layers. This method of hardening by making compound glass has been used for boiler gauge tubes.

The second method, namely, that of controlling the co-efficient of expansion, has been the basis of many successful developments in recent years. The co-efficient of expansion of glass is intimately connected with its composition, and it has been found possible to make glasses of linear thermal expansion varying between 30 to 130×10^{-7}, so that on the one hand the expansion can be made much the same as that of the more expandible metals, and at the other extreme, approaching that of fused quartz. These results can be traced back to the systematic work of Schott, who in 1892, showed that the different constituent oxides had each a definite effect on the total expansion of the glass, and later the co-efficient of expansion was shown to be additive in character and capable of calculation. This work had found immediate practical application in the manufacture of heat-resisting glasses. Thermometer glasses of low depression constant and fairly low expansion represented one type, and Jena chemical glassware constituted another. Indeed, practically all modern glasses used for chemical ware are not only resistant to corrosion, but are also in varying degrees heat-resisting. Silica and boric oxide, for instance, increase the resistance, particularly to water and acids, as well as diminish the co-efficient of expansion. Lamp chimneys and miners' lamp glasses at Jena were made from a glass constituted largely of silica, boric oxide, antimony oxide and sodium oxide. In the combustion tubing glass made by Messrs. Kavalier, the most important constituent is silica, which reaches the very high value of more than 79 per cent., and successful combustion tubing made in this country also possesses a very high silica content. Kavalier's combustion tubing contains no boric oxide, and the basic oxides (potash and lime) used as fluxes, prevent the production of a low expansion glass. Modern glasses contain boric oxide in very considerable amount. Pyrex glass contains roughly 80 per cent. of silica and 12 per cent. of boric oxide, and there is a tendency to make chemical glassware and heat-resisting ware strongly acid, since the acid oxides, silica and boric oxide, are far superior to the basic oxides in giving low expansion.

In practice the use of silica and of boric oxide beyond a certain limit is attended by certain difficulties. With silica the difficulty is merely that of obtaining a sufficiently high temperature. Recent investigations have shown that with a glass composed of silica, boric oxide and soda, the amount of the last-named being constant, the durability rises to a maximum somewhere in the neighbourhood of 11 to 12 per cent. of B_2O_3; thereafter, the durability rapidly diminishes until, when 40 or more per cent. of boric oxide is present, the glass rapidly breaks up. Boric oxide is also limited because after a certain concentration has been reached, not only does the glass become unstable, but the expansion also increases. Nevertheless, by combining these two oxides in boro-silicate glasses big advances have been made possible. All the chemical glassware made in this country has been of the boro-silicate type.

The Corning Glass Co. of America led the way in using glass for baking and cooking dishes, tea pots, etc., and this development has already assumed big proportions. In this country Messrs. Ackroyd and Best are making cooking ware, and the manufacture in Great Britain is likely to be extended. Messrs. Kavalier, in Czechoslavia is the latest firm to make heat-resisting ware for domestic purposes.

The problem is to discover refractory materials which will withstand the action of fused silica at temperatures of 1550° to 1750°. Pyrex glass is melted in tank furnaces operating at a temperature not less than 1500°, and open hearth steel furnaces are operated at considerably higher temperatures, so there will be no no great difficulty in proceeding further when suitable furnace material is available. Already preliminary attempts have been made to produce glasses by adding small amounts of titania and zirconia to silica, the objects being to increase the resistance of the fused silica to devitrification and to attack by basic materials. Experiments have been made with glasses containing a series of oxides, including titania, but information has not been forthcoming of the effect on thermal expansion. At Sheffield both zirconia and titania have been added to ordinary glasses; when several per cent. of titania is present, small crucibles of glass can be cooled down without special precautions to yield unbroken lumps. This indicates either reduced thermal expansion or increased mechanical strength; in any case an improved heat-resisting glass. Given the requisite optical properties, the addition of either zirconia or titania to optical glass might make it possible to obtain a bigger yield of glass by reducing the amount of splintering.

INSTITUTE OF BREWING

At a meeting of the London Section, held in the rooms of the Institute of Chemistry on February 12, Messrs. H. Langwell, F.C.S., and H. Lloyd Hind, B.Sc., read a paper on "Cellulose Fermentation with Special Reference to the Utilisation of Spent Hops and Brewers' Grains." Hitherto, the only method of making cellulose available for the production of alcohol has been to hydrolyse it with mineral acids, such as sulphurous or hydrochloric acid, and then to ferment with yeast the hexose so produced, but commercial success has not so far attended this procedure. The authors seek to overcome this difficulty by introducing the biological factor at an earlier stage, using for the purpose, not yeast, but a slender rod bacillus $(4\mu \times 0{\cdot}4\mu)$, capable of fermenting cellulose without preliminary treatment. The organism—which has no name and is derived from horse-manure—is a spore-forming anaerobe with an optimum working temperature of 140°—150° F. (60°—65° C.). At such a temperature the bacillus can ferment as much cellulose in four days as would require 110 days at 80° F. ; in addition, the high temperature which can be employed renders the use of pure cultures unnecessary, since automatic pasteurisation is ensured, the continued use of the process actually causing the strain to become purer and purer. Potash and phosphates should be present, and ammonium salts suffice as the source of nitrogen.

There are two defects in the useful application of the organism : (1) Its extreme susceptibility to traces of copper, even when present in amounts such as occur in spent hops which have been boiled in a copper ; and (2) the fact that it cannot attack pure cellulose in the presence of lignin, and thus cannot be used in fermenting sawdust, although sulphite pulp and all non-lignified cellulose can be readily fermented.

The products of fermentation include alcohol, acetic, lactic and carbonic acids, together with marsh gas and hydrogen, in ratios which vary under different conditions, but can be largely controlled. A ton of fermentable matter yields about 15,000 cb. ft. of gas and 120 gallons of liquid products. Most cellulosic material yields from 40 to 70 per cent. of fermentable matter.

Spent hops are a cellulose waste product of which some 12,500 tons are available annually in the British Isles. Hitherto it has been very difficult to dispose of them, many brewers being forced to pay for their removal. As manure, litter and fodder they have found a certain sale, but if they could be utilised for the production of alcohol and other substances, their value would be greatly enhanced, although the success of their conversion to alcohol depends on a low price. This involves the elimination of carriage, so that it would be necessary to erect the necessary factories at large brewing centres to work up the spent hops of the district. No definite idea of the financial possibilities of the utilisation of spent hops can be given until more exhaustive trials have been made, but the experiments so far made show that spent hops will yield about 40 gallons of a mixture of alcohol and acetic acid per ton of dry material. From the acetic acid, acetone and valuable solvents may be obtained valued at about £10. Grains which are readily fermentable generally give a higher yield, amounting to 70 gallons of solvents per ton, valued, say, at £17 10s. Valuing wet grains at 9s. per quarter, and the cost of drying at from £4 to £5 per ton, a price of about £10 per ton for dried grains is arrived at.

INSTITUTE OF CHEMISTRY

At the Annual General Meeting, held on March 1, the President (Mr. A. Chaston Chapman, F.R.S.), in presenting the Report of the Council, remarked on the progress of the organisation of the profession of chemistry under the Institute. The roll of Fellows and Associates had increased during the past year by 421, to a total of 4,062, and the register of Students by 72, to a total of 955. The Institute was taking an increasing part in the affairs of the country and was frequently appealed to by Government Departments and other authorities for advice and help. Science was coming into its own and scientific men would be given their proper status and rightful place in the affairs of the country. The Institute, in common with other societies and associations, was actively promoting a spirit of solidarity and comradeship among all concerned with chemistry, with a view to welding the profession into one coherent whole. With the advances which chemistry was making in all directions, and with the high degree of specialisation of to-day, many societies had come into existence, but the dangers of decentralisation were greatly lessened by the practice of holding joint meetings of the societies. The direct utilisation by the State of the services of the professional chemist was not only of immediate concern to chemists themselves, but also of high importance to the community at large, and in the interests of the country no less than in those of its members the Institute was bound to do all it could to ensure that the relations between the appointing authorities and those who held official chemical positions were of a satisfactory character. Unfortunately, some public bodies did not appear to be aware of the expensive nature of the chemist's training or of the difficulties and responsibilities connected with his work, and consequently the Institute sometimes found that the advertised conditions of certain public bodies were not commensurate with the importance of the services demanded. It was of public importance that men of good general education, of high professional attainments, and of high moral character should be chosen to fill these public positions. For the appointment of public analyst the remuneration offered was often entirely inadequate and, in some cases, even below that paid before the war, notwithstanding the enormously increased work and responsibility attaching to the post. A statement on the whole subject would shortly be published by the Institute jointly with the Society of Public Analysts. There was a tendency on the part of local authorities to utilise the services of unqualified or imperfectly trained persons in routine processes, a practice against which the Council had felt bound to protest vigorously on the ground that it constituted a serious danger to the community and involved waste of public money. The Institute had also been obliged to complain of the competition of State-aided institutions with private practitioners, and it was a source of gratification that the Ministry of Agriculture and Fisheries had recognised the legitimate grievance of the private practitioner and had taken steps towards limiting the work done in Agricultural Institutions receiving its grants to that required for strictly educational purposes or necessary to the advisory work of the Institutions.

The disinterested zeal of the scientific worker was something without parallel in the whole world, but it was not wise for any country to presume too much on this disinterestedness. Science was one of the greatest and freest of all givers, but it had a right to demand that it should receive that recognition and that proper position in the councils of the country to which it was entitled.

The President said that although the supply of qualified chemists exceeded, for the moment, the demand, he did not think that there was cause for serious alarm. The profession had attracted a larger number of young men during the last four years than in any previous corresponding period, but he was very optimistic in regard to its future, and it was a remarkable fact that, notwithstanding the increased output from the colleges and the intense industrial and commercial depression, the new members of the profession were being steadily absorbed. This absorption might be taken as a definite indication that chemistry was more highly valued by the manufacturer than formerly, and as evidence that the leaders of industry and commerce were turning more and more to science to assist them in the solution of their various problems.

CHEMICAL SOCIETY

The Annual Dinner will be held on March 22, in the Hotel Cecil, and it is expected that a number of foreign guests will be present. Prof. Le Chatelier, F.R.S., the Abbé Sanderen, and Prof. Urbain will represent the French Chemical Society, and MM. P. Kestner, Jean Gérard, Maurice Deschiens, and J. A. Le Bel, F.R.S., will represent the French Society of Chemical Industry. Of these, Prof. Urbain, the Abbé Sanderen, and Prof. Le Chatelier are honorary members of the Society of Chemical Industry. Tickets for the Dinner cost 12s. 6d. (not including wine), and applications should be sent as soon as possible to S. E. Carr, Esq., Chemical Society, Burlington House, Piccadilly, London.

Five papers were communicated to the meeting of the Chemical Society on March 1, Prof. H. B. Dixon presiding.

In the first paper, entitled "Co-ordination compounds and the Bohr atom," Prof. Sidgwick briefly outlined the Bohr theory, and showed its applicability to compounds, illustrating this especially by reference to double compounds of platinum, and correlating it with the work of Werner. The arrangement of electrons in groups of 4 and 6 was emphasised, and this was contrasted, whether the compounds ionised or not, with the stable configuration of the atoms of the rare gases, showing also how apparent contradictions to the laws of valency could be explained.

Mr. W. H. Gray gave a paper on silver salvarsan, dealing with the reaction between salvarsan and silver nitrate. He quoted contentions of previous workers since Erlich, on the reaction with which the evidence he adduced did not agree.

The third paper, "On the propagation of the explosive wave. Part I. Hydrogen and carbon monoxide mixtures," by H. B. Dixon and N. S. Walls, was read by Prof. Dixon, who mentioned that Prof. Bone and Prof. Wheeler were working on the problem of combustion of the same gas mixtures under different conditions. The suggestion that it would be of interest to measure the rate of the explosive wave in the case where two combustible gases were present, was made by Langmuir. Mixtures of hydrogen and carbon monoxide were therefore tested with: (1) enough oxygen to combine with both of the gases present, and (2) only sufficient oxygen to combine with one of the constituent gases. The rates of the explosive wave were shown under these conditions. The results were compared with a relay race and a three-leg race. As the firing was initiated with electrolytic gas Prof. Dixon suggested that the combination of these gases probably produced a temperature too high for the carbon monoxide to be oxidised. Prof. Bone, in the discussion, mentioned that he had carried out experiments under pressure and also at ordinary atmospheric pressure, which was attended with experimental difficulties which had been eliminated. He referred to the different results which were attained under varied conditions, and observed that the problems still to be solved in the combustion of water-gas mixtures were greater than those which had already been elucidated. Mr. Garner pointed out the bearing of the radiation hypothesis on the question, and Prof. Bone said he had taken that into consideration in his paper.

A paper on "The molecular configuration of polynucular aromatic compounds. Part II. 4 : 6 : 4 trinitrodiphenic acid and its resolution into optically-active components," by G. H. Christie and J. Kenner, was read by the former. The authors have resolved the acid.

CORRESPONDENCE

THE CALCIUM CARBIDE INQUIRY

Sir,—I am afraid that your readers must be weary of this topic, and I should have refrained from any further communication upon the matter but for your request that I should send you any comments I might think desirable upon Sir William Pope's further articles purporting to deal with this subject.

At the outset, I feel compelled to state, once again, that in this correspondence I have never discussed the question whether Calcium Carbide is a synthetic organic compound. Accordingly, I have no comment to make upon the reasons Sir William advances in his articles for the view he holds that it is such a compound. The industry he has devoted to the selection and grouping of his facts and the cogency of his reasoning in applying them in support of his view, make it all the more to be regretted that his absence from this country at the time rendered it impossible for him to give evidence in support of the application.

The origin of this correspondence was a letter Sir William wrote to the *Times* criticising, as I thought, and still think, unfairly, the conduct of the Calcium Carbide Inquiry by the learned Referee appointed as provided by the Act by the late Lord Chancellor. If I may be allowed to quote one or two passages from our respective letters to the *Times*, they will, I think, serve quite sufficiently to test, when contrasted with what Sir William has since written, whether I was justified in my intervention on behalf of one, who, by his position as Referee, was precluded from replying to Sir William's criticisms. I take, in the first instance, the mistranslation of a passage from Meyer and Jacobson's *Lehrbuch der organischen Chemie*, and my excuse for so doing is the prominence given to the matter in Sir William's letter to the *Times*. I agree that the passage was wrongly translated and I pointed out the mistake at the time, but the Referee did not accept my emendation. The dispute between Sir William and myself as to this matter appears quite clearly from the following extracts from our letters.

He wrote: "The referee, in his decision, quoted a very carefully worded definition by a German authority, but quoted it in the form of a mistranslation which entirely altered its meaning; *on this erroneous statement of fact, the referee rejected the application.* Calcium Carbide, one of the most typical synthetic organic compounds, *is declared by the referee, on a false translation of a German definition, not to be an organic chemical.*"

I wrote: "*On the evidence as a whole, and not on any isolated definition*, such as Sir William says was mistranslated, *the Referee decided the case*, holding that the applicants had not established that Calcium Carbide was a synthetic organic chemical."

From the words in these extracts which I have underlined, the issue between us is made perfectly clear. What is Sir William's position now? In the article appearing in your issue of February 9, he now says that the Referee attached "considerable weight" to this passage. Doubtless he did, as also to many other matters in the evidence, but to say that he attached considerable weight to it is very different from saying, as Sir William did originally, that the Referee decided the case on it, and seems to me to be saying what I have throughout contended was the fact.

With regard to a broader aspect of the controversy, I wrote in my letter to the *Times*:—

"I submit that, had Sir William been better informed, he would have refrained from criticising these inquiries or their results, at any rate in language which does not bear the impress of that accuracy in statement or care in consideration which in fairness to the learned Referee and those who have taken part in such inquiries, may reasonably be demanded."

He had written that these inquiries "have become ridiculous farces played to the shame of British methods of legal procedure," referring more especially, as his letter showed, to the Calcium Carbide Inquiry. He now admits that the evidence in that case justified the Referee's decision. Need anything more be said? Sir William's changed position in this respect, as also in the matter of the mistranslation, amply warrants, as I submit, the views I ventured to express upon his letter.

In his article, Sir William adopts a new attitude. His quarrel is now with the evidence which he calls, "a sketchy outline of the subject," and in another passage, "trivialities." I quote the sentence; it is a characteristic passage:—

"I am well aware that the trivialities which he" — meaning myself — "describes sententiously as 'the evidence' were received with great decorum, although they would have excited hilarity if produced before an assembly of Chemists."

The evidence—by which I mean the oral and documentary evidence—and I do not know—even to please Sir William—how to expand the expression further, was that of chemists, and was given in an assembly, the major portion of which was composed of chemists. It excited no hilarity, and I am sure it was received with due decorum. I leave it to Sir William to decide whether in allowing himself to speak so lightly of the views expressed and the reasons advanced in support of the same by his distinguished colleagues, he is treating those gentlemen with the respect due to them.

Sir William, in his last article, also discloses that he has a quarrel with the legal profession. His references thereto are, as it seems to me, coming from him, unexpectedly tolerant. They are, however, characteristically based upon misconception of the pertinent facts. He says:—

"The case is a very simple one and if my contention is correct it follows that the legal profession has failed in its duty by dealing so perfunctorily with the question submitted to it that an indefensible decision has had, perforce, to be pronounced."

Bearing in mind that Sir William had in an earlier part of the article admitted that the learned Referee was justified in his decision by the evidence upon which he pronounced it, and so had absolved the only member of the legal profession to whom any question was submitted, the meaning of the passage is obscure. If counsel engaged in the case are intended to be referred to, I naturally hesitate to say anything. I may, however, be permitted to make one or two remarks, on the assumption that such is the intention. In the first place, the word "perfunctorily" is one, the use of which in respect of an inquiry which lasted many days, may occasion surprise and some doubt as to Sir William's object in using it. I think, however, that elsewhere in his article he has made it sufficiently clear that his choice of the word was determined by his view that the evidence was not sufficiently exhaustive. If I am doing him justice in so regarding the true intent of the word in the passage I have quoted, I am utterly unable to understand wherein the legal profession, according to Sir William, failed in its duty. I suspect that when he wrote it, he was labouring under the erroneous belief that counsel have the duty not only of presenting their clients' case, but also of obtaining the evidence in support of it. He will probably recognise on reflection that in general counsel have to use the materials supplied to them, and that in such a case as the one under consideration, the scientific gentlemen, by their advice and evidence, provided the materials. As I do not believe that he doubts that every legitimate use was made of all such materials by the counsel for the respective parties to the dispute, it seems to me that the only basis for the sentence I have quoted above is Sir William's conviction, for which I have the greatest respect, that the application would have been greatly assisted by his own advice and evidence.

One further matter, and only one, I feel I must say something about. He refers to the question I put to him, whether he thought the Referee would have had the assistance he, Sir William, considered desirable, had the assessor been one of the eminent gentlemen who gave it as their opinion that Calcium Carbide was not a synthetic organic compound. I refer to this only to say that Sir William is quite wrong in thinking that in putting the question I had any idea of claiming for His Majesty's counsel or for any "practitioners of the law," the exclusive possession of the virtue of impartiality, much less of denying possession of that virtue by Sir William's colleagues. I put the question quite seriously and believing, as I still do, that the assessor contemplated by my question honestly held the view which he supported by his evidence, that Calcium Carbide was not a synthetic organic compound. When Sir William says :—"I am quite sure that such an assessor would have warned the Referee that the evidence placed before him was so fragmentary as to be fictitious, that he was being misled, and that he would do well to call for facts upon which to base a decision" he is attributing to those of his colleagues who gave it in evidence that Calcium Carbide was not a synthetic organic compound, that their evidence was the reverse of their knowledge and convictions. Again, I suggest to Sir William that his colleagues may reasonably complain that he has overstepped the limits which courtesy demands should control in such a controversy as that which has developed from our respective letters to the *Times*.

I apologise for the length of this letter and conclude by putting it on record that I do not intend or desire to make any further communication on the subject of the Calcium Carbide Inquiry, and that I leave the field to Sir William.—I am, Sir, etc.,

The Temple, London　　Arthur Colefax
February 27, 1923

THE SMOKE PROBLEM

Sir,—A few days ago the horticultural expert of the *Daily Telegraph*, calling attention to the damage done to city gardens by smoke, stated:—"The prevention of fog has so far baffled chemists, physicists and other scientific men—and even modern London County Councillors." If the chemists and other scientific men were allowed their own way a good deal could speedily be done to mitigate the smoke nuisance.

Prof. Bone, I think, has pointed out that the open, domestic fire, which is a luxury in countries with a "diviner air," is a necessity here, and whatever house-heating methods other people may adopt, the Englishman will not be robbed of his open fire. This being admitted, together with the fact that the Briton's home fires account for 75 per cent. of our smoke pall, what fuel can we offer him to mitigate the nuisance ? The answer is that smokeless semi-cokes can now be obtained at reasonable prices, which give an excellent fire in any good, modern grate. The use of such fuels is extending enormously, and it is not extravagant to believe that gradually a brighter Britain will result.

As to smoking factory chimneys, half-a-dozen smoke inspectors, with the powers of our very efficient factory inspectors, could do a great deal, and as their experience grew their advice would be welcomed by manufacturers, who would learn how to effect vast economies with little or no interference with industry.—I am, Sir, etc.,　　N. F. Graham

THE NOMENCLATURE OF COAL CONSTITUENTS

Sir,—I notice that in your editorial reference of the 23rd ultimo to Mr. A. R. Pearson's recent paper, you make certain comments upon the nomenclature of coal constituents and question the desirability of adding a new phraseology to a subject regarding which so little definite is known.

I have long been of the opinion that the present system of nomenclature is in need of reconsideration and reform. The terms *alpha*, *beta*, and *gamma*, are being used to-day in ways which confuse and obscure the whole subject, just as formerly the terms "resinic" and "cellulosic" were unscientifically applied to constituents which had not been properly characterised. The subject was referred to in the recent Fifth Report of the Fuel Economy Committee of the British Association, and, with your permission, I should like now to reproduce, without further comment, the following paragraphs from that report for the consideration of your readers :—

"It has long been recognised that bituminous coals contain three easily distinguishable components, which until recently had usually been designated (*a*) 'mother of coal' or 'mineral charcoal,' (*b*) 'dull hard coal' (German = 'Mattkohle'), and (*c*) 'bright coal' (German = 'Glanzkohle'), respectively, the last named being a structureless, lustrous substance with a conchoidal fracture. Recently Stopes (Proc. Roy. Soc., B. 90 (1919), p. 470) proposed new names for them, namely (*a*) *fusain*, (*b*) *durain*, whilst (*c*) is termed by her either *clarain* or *vitrain*, according as it does or does not contain recognisable plant tissues and structures. In putting forward these proposals Stopes recognised that none of the four said ingredients (with the possible exception of vitrain) are either homogeneous or chemical molecular units ; also that they do not even approximately represent the crystals in a petrological section of a rock. Provided that such qualifications are kept clearly in mind, and that it be realised that clarain may prove to be merely vitrain in which plant structures occur in suspension, the Committee sees no great objection to the provisional substitution of the proposed new names for the older ones, regarding the matter more as one of convenience than as involving any new principle."

"The Committee also feels that the growing practice among coal-chemists to use the terms *alpha*, *beta*, *gamma*, etc., to designate the several components obtainable from the coal substance by fractional extraction of it by means of various solvents, is one which, unless regularised in some definite way, is likely to lead to much confusion and obscurity, to the detriment of progress. It is obvious that coal may be 'fractionated' in as many different ways as there are suitable solvents and modes of applying them ; and therefore unless, as the result of some particular treatment or procedure, components of a reasonable degree of purity and well-defined properties are isolated, it is undesirable that definite names should be assigned to them, as though they were the actual chemical constituents of the coal instead of unknown mixtures of them. The Committee, therefore, would suggest that the time has come when chemists should agree in conference upon some common plan of labelling, such 'coal fractions' which, whilst recognising them to be such, shall also in some way indicate how they have been obtained.

"Supposing, for example, that a particular investigator extracts a coal with two solvents A and B, he might designate the fraction which is insoluble in both as the α AB fraction, whilst β AB might be used to denote the fraction which is soluble in A but not in B, and the γ AB that which is soluble in both A and B, assuming all solvents to be used at their respective boiling points at atmospheric pressure. Thus, a fraction termed the 'α-pyridine-chloroform' fraction would mean the residual insoluble portion of a coal after successively extracting it with pyridine and chloroform at their respective boiling points ; the 'β-pyridine-chloroform' fraction would be that portion of the pyridine extract which is insoluble in chloroform ; whilst the 'γ-pyridine-chloroform' fraction would mean the portion of the coal which is soluble in both pyridine and chloroform, and so on. In cases where the coal is extracted at some particular temperature other than the boiling point at atmospheric pressure of the solvent employed, the actual temperature employed might be designated by putting it in small type above the name of the solvent, thus '-benzene 120°' denoting that benzene had been used at 120° C."—I am, Sir, etc., William A. Bone

"BAYBERRY OIL"

Sir,—I have recently heard of an oil (I presume an essential oil) known as "Bayberry oil." Does anyone know what this is, from what it is manufactured, and from where it can be obtained ?

I am greatly interested and would much appreciate any information.—I am, Sir, etc.,

Birmingham. W. Leslie Carter

"NOTES FROM HEATHFIELD"—A QUERY

Sir,—I cannot find the poem, "The Progress of Man," referred to by the Rev. B. V. White, in any of my books, and shall be glad if you will tell me where it can be found.—I am, Sir, etc., Sales Manager

Liverpool, March 5, 1923

ADVERTISEMENTS

SIR,—As a member of the Society and one who has some knowledge of the technicalities of advertising, I was particularly interested in your observations on this subject in the current issue of the *Journal.*

Whilst there has recently been a noticeable improvement in its advertisement pages, it still, in common with most technical publications, contains an unduly large proportion of decidedly mediocre and even antiquated advertisements. Many of them remain unchanged for months, and one or two have actually remained in their present form for years! How many purchasers would a publication have if the editorial pages were similar? Yet, what are advertisements but news of advertisers' products?

The comparatively uninteresting appearance of the advertisement section is due, not to the advertising staff of the publication—who are usually only too willing to help advertisers to get the best result from the space taken—but to the apathy of the advertisers themselves. Many seem to regard the buying of space as a sort of necessary evil or as a "duty" that they owe their trades' journal.

It is almost incredible that, to-day, there should be anyone who does not realise the necessity for, and the potentiality of, advertising, and its efficacy when properly conducted.

That there are such people is only too evident, especially among advertisers in the technical press. This is all the more remarkable inasmuch as the majority of such advertisers have exceedingly well-printed and convincingly-written literature of their products. Yet they do not even make an effort to induce prospective buyers to write for that literature!

Your implication that the prospective buyers are to be found in the counting-house and the secretary's office seems hardly likely to be the case as regards the products advertised in a technical publication. Surely, such buyers are to be looked for among the technical staff and those who have the decision with regard to the spending of money—viz., the directors, managers and heads of technical departments—these are the people whom it is necessary to reach and to interest.

And there is no reason why the advertisement pages should not, in their way, be as interesting and informative as the editorial pages. They can be made so, with corresponding advantages to both the publication and the advertisers, but only when the latter awake to the fact that their advertising is part and parcel of their sales organisation—that an advertisement is twin brother to their salesman—and should be equally efficient.—I am, Sir, etc.

HARRY V. HODGSON

Balham, S.W. 12.

PERSONALIA

Prof. A. Smithells, F.R.S., has been re-appointed Pro-Vice-Chancellor of Leeds University.

The Council of the Institution of Electrical Engineers has made the second award of the Faraday Medal to the Hon. Sir Charles Algernon Parsons, K.C.B., F.R.S., honorary member of the institution.

Mr. G. W. Robinson, lecturer in Agricultural Chemistry in the University College, North Wales, Bangor, has been awarded a Travelling Research Fellowship by the Ministry of Agriculture, and will shortly proceed to the United States to study soil problems.

* * *

Prof. J. W. Caldwell, emeritus professor of chemistry in Toulane University, Louisiana, has died at the age of 80.

We regret to announce the death of the well-known metallurgist, Mr. W. M. Hutchings, at the age of 73. Mr. Hutchings was mainly associated with the lead industry, and published numerous papers on the petrology of shales, clays and slates. He was at one time a member of this Society.

NEWS AND NOTES

AUSTRALIA

Gold Output in 1922

According to a return furnished by the Under-Secretary for Mines, the production of gold in Australia during 1922 amounted to 25,222 oz. fine, valued at £107,139, compared with 51,175 oz. fine, valued at £217,370 in 1921, and the lowest recorded output since the first discovery of payable gold in Australia in 1851.—(*Bd. of Trade J., March* 1, 1923.)

NEW ZEALAND

Discovery of Glass-making Sand

The *Auckland Weekly News* announces that, during prospecting for coal at Mount Somers, Canterbury, an immense body of sand was discovered. Analysis revealed that the sand contained 99 per cent. of silica, and that it was admirably suited for glass-making.—(*Raw Materials Rev., Feb.*, 1923.)

UNITED STATES

Lead and Zinc Production

According to estimates published by the United States Geological Survey, the output of refined lead in the United States during 1922 was 531,000 tons, of which 461,000 tons was produced from home ores and 70,000 tons from imported ores. The total in 1921 was 448,589 tons. The production of zinc during 1922 was 339,000 tons (200,500 tons in 1921), of which all but 1,000 tons came from home ores.

GERMANY

The Atomic Weights of Boron and Silicon

Prof. A. Stock and E. Kuss, in the *Berichte* (1923, 314), announce that they have utilised the reaction between gaseous boron trihydride, B_2H_6, and water, which takes place according to the equation $B_2H_6+6H_2O=2H_3BO_3+6H_2$, to redetermine the atomic weight of boron. Six determinations using pure trihydride gave an average value of 10·8055, which is somewhat lower than the figures obtained by analysis of the trichloride, viz., 10·82 to 10·84. A similar determination of the atomic weight of silicon by hydrolysis of silicon tetrahydride also gave a value lower than 28·3, which is generally accepted.—(*Chem.-Z., Feb.* 17, 1923.)

The Occupied State Mines

The following details concerning the State mines of Westphalia recently occupied by the French are taken from the annual report for 1921 of the " Preussischen Bergverwaltungen."

		1921	1920
Number of workers		28,526	26,618
Output of coal	Tons	4,685,155*	4,377,389
Sales—			
Coal	,,	2,472,279	2,450,405
Coke	,,	1,499,097	1,414,237
Briquettes	,,	23.049	24,874
Ammonium sulphate	,,	18,861	18,396
Tar	,,	31,792	31,267
Benzol	,,	9,823	9,122

* About 5% of the total output of the Ruhr district.

In 1921, 3,246,997 tons of this coal and coke was consumed in Germany and 416,748 tons exported (339,050 tons to France), figures which show a decrease of 164,353 tons and an increase of 260,278 tons, respectively, compared with those for 1920.

GENERAL

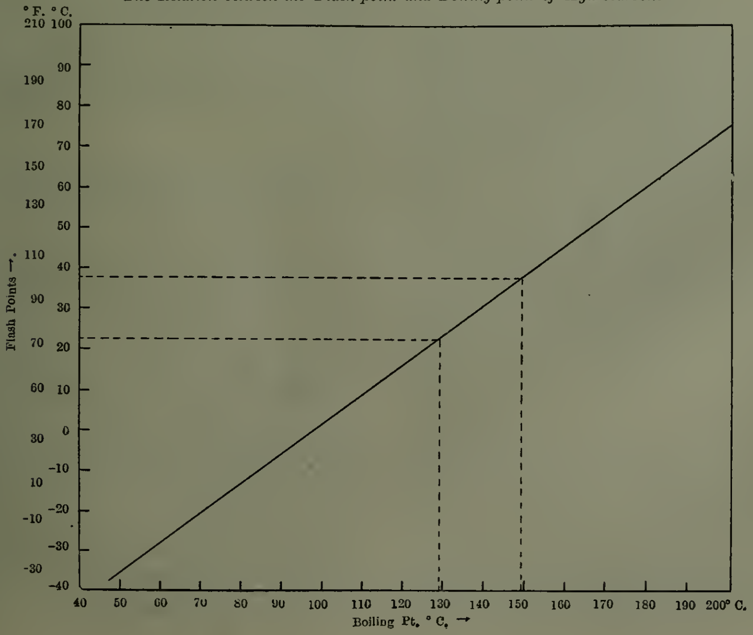
Relation between Flash-point and Boiling-point

Dr. W. R. Ormandy and Mr. E. C. Craven call our attention to an interesting relationship which has been found between the flash-point and the boiling-point of a number of inflammable liquids. The diagram printed below shows this clearly. Any point on the oblique line shows the boiling-point as the abscissa and the flash-point as the ordinate. A liquid boiling at 150° C. will have a flash-point of 100° F. or 38° C. They have verified this relationship for pentane, hexane, heptane, benzol, toluol, naphthalene, phenanthrene, amyl benzene, cyclohexanol and decahydronaphthalene. The relationship, with suitable observations, holds for mixtures of these substances. Expressed as a formula, the rule may be stated :—

$$F.P.=0{\cdot}736\ (B.P.+273)-273$$

where F.P. is the flash-point in degrees centigrade and B.P. is the boiling-point in degrees centigrade. This handy rule, if found to be reliable, should be of great value to those who·

The Relation between the Flash-point and Boiling-point of Hydrocarbons



handle large quantities of petrol and petroleum, or who have to consider the alterations in flash-point or boiling-point suggested or enforced by legislation. A somewhat similar relationship, but involving a different factor, has been found for a number of the alcohols.

Messrs. Ormandy and Craven state that this law is true for pure hydrocarbons and mixtures of pure hydrocarbons; but all commercial hydrocarbons appear to contain dissolved gases, which reduce the flash-point to varying extents.

The Polish Sugar Industry

Sugar production in Poland is making steady progress, and 88 factories are now at work. In 1922, 266,773 acres were planted with sugar-beet, the production amounting to 330,000 metric tons (compared with 155,000 t. in 1921), of which 150,000 t. are available for export.

Swedish Iron and Steel Trade in 1922

According to statistics supplied by the Swedish Consulate-General in London, imports of iron and steel into Sweden during 1922 amounted to 139,700 tons as compared with 129,500 tons in 1921, whilst exports of iron and steel amounted to 174,300 t. and 147,600 t. respectively.—(*Bd. of Trade J., Feb.* 15, 1923.)

COMPANY NEWS

COURTAULDS, LTD.

The report of the Directors of this Company states that the profit during 1922 amounted to £3,018,432, which compares with £1,684,593 in 1921 and £1,804,796 in 1920; £418,467 was brought forward, £1,000,000 was carried to reserve and £639,899 carried forward, leaving £1,800,000 available for the payment of the dividend, which has been fixed at 15 per cent., compared with 11¼ per cent. in 1921 and 23⅜ per cent. in 1920. The shares held in the Viscose Co. of America have been exchanged for shares in the American Viscose Corporation with an authorised capital of $100,000,000, of which $93,559,500 has been issued. The par value of the shares received in exchange by Courtaulds, Ltd., is $85,014,900, valued in the balance sheet at £7,804,021, thus bringing up the share capital to £12,000,000. The reserve is stated to be £3,000,000 and investments in securities, etc. amount to roughly £7,000,000.

BRADFORD DYERS' ASSOCIATION, LTD.

At the annual meeting of this Association held on February 28, Sir Milton S. Sharp, who presided, said that the textile trade had progressed markedly towards recovery in 1922. The great difficulty confronting the cotton industry was the high price of cotton, due largely to the fact that whereas in 1901-2, 71·8 per cent. of the total American cotton crop was exported, domestic consumption had increased so greatly that in 1920-1 only 41 per cent. of the crop was exported, despite the fact that the crop in that year was 40·6 per cent. greater than in 1901-2. The development of Empire cotton resources was absolutely essential and the British Cotton Growers' Association would certainly leave nothing undone to ensure this. There were, however, possibilities of substitute fibres, of which an example was the new Arghan fibre grown in the Malay States. After referring to the burden of taxation and the unemployment problem, Sir Milton Sharp discussed the Dyestuffs (Import Regulation) Act and said that the Act was passed to ensure the establishment of the dye-making industry on account of its vital importance to national safety, and he had no sympathy with the outcry for its repeal. Although he was not entirely in agreement with the way in which it had been administered, the Act was doing effectively the work for which it was designed, for whereas our consumption of British made colours averaged 22 per cent. of the total in 1910 to 1914, in 1922, 77·66 per cent. of our total consumption was British-made. The British makers were extending their ranges of the better types of colour, but could not yet equal their continental competitors in variety. The high prices of dyestuffs were causing loss of business to foreign competitors, and he agreed with the suggestion of the Colour Users' Association that the proceeds of the sale of Reparation dyestuffs should be utilised as a contribution by the Government towards establishing the dye-making industry. The dividend on the ordinary shares was fixed at 7s. per share, less income-tax, for the year ended December 31, 1922, making a total distribution of £406,943; and £467,369 was carried forward.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for March* 1)

TARIFF CUSTOMS EXCISE

Australia.—"Dumping" duties have been applied to perfumed spirits, spectacle glass and binoculars of German origin.

Colombia.—The duties of the customs tariff are increased by 10 per cent. from March 1.

France.—The export duty on raw bones has been reduced. Sugar may not be exported.

Germany (Occupied).—A statement of the position regarding customs duties and trade control is given in the current issue.

Newfoundland.—The surtax, payable on most imports, of 25 per cent. of the customs duties, has been abolished.

New Zealand.—The embargo on German goods is to be removed as from September 1.

Norway.—A temporary increase of 20 per cent. has been applied to all imports, except spirits, cork stoppers, and sugar.

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

GOVERNMENT ORDERS AND NOTICES

Safeguarding of Industries Act—Part I

The Board of Trade has received a complaint that formaldehyde has been improperly included in the lists of articles dutiable under Part I of the Act. The complaint will be submitted, in due course, to the referee, and those interested should communicate immediately with the Assistant Secretary, Board of Trade (Industries and Manufactures Department), Great George Street, S.W. 1.

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Overseas Trade Department

In reply to Mr. Moreing, Sir W. Joynson-Hicks said that the staff of the Department of Overseas Trade at home numbered 369 persons, and the staff abroad included 34 commercial diplomatic officers, 11 trade commissioners and clerical staffs of about 120. The Department was also responsible for the administration of the consular service comprising 390 salaried officers—Feb. 26.)

Exports of Morphia

Mr. Bridgeman informed Mr. Gilbert that the exports of morphia, heroin and their salts from the United Kingdom totalled 322,464 ozs. in 1920, and 77,365 ozs. in 1921. The figures for 1921, on the contrary to those for 1920, included exports by parcel post and exports in the form of preparations. Average prices during 1921 were 12s. to 14s. for morphine and 10s. to 12s. for morphine salts.—(Feb. 26.)

German Alizarin

Replying to Mr. T. Thompson, Sir W. Joynson-Hicks stated that alizarin obtained under the Reparation scheme to meet Indian requirements had been handed to the British Alizarin Co. under an arrangement made between that company and the Government of India for distribution in India. No alizarin had been requisitioned for consumption in the United Kingdom.—(Feb. 26.)

Dyestuffs Import Regulation Act

Sir W. Joynson-Hicks, answering Mr. T. Thompson, said he was aware that the referendum recently taken among colour users resulted in a majority in favour of the repeal of the Act. He had no information of the firms to which the questions were sent or how the list was compiled, but only about 50 per cent. of the questions were returned. He did not propose to take any action.—(Feb. 26.)

Trade Marks Branch, Patent Office

Viscount Wolmer informed Mr. Hannan that the Treasury had approved a scheme for reorganising the Trade Marks branch of the Patent Office which would greatly reduce the present arrears of work.—(Feb. 26.)

Patent Fuel Industry

In a written reply to Mr. M. Jones, Lieut.-Col. Lane-Fox stated that he was aware of the plight of the patent-fuel industry in South Wales on account of the high price of pitch, the vital binding ingredient in the manufacture of patent fuel from small coal, but he believed that it was incorrect to attribute the high price of pitch wholly, or even mainly, to the use of tar and pitch for road-making. The representations recently made by the patent-fuel manufacturers to the Ministry of Transport were being considered.—(Feb. 26.)

Aluminium Hollow-ware

Answering Mr. Bonwick, Sir P. Lloyd-Greame said that the imports of aluminium hollow-ware during the quarter ended December 31, 1922, totalled 288 tons, valued at £43,318, compared with 294 tons, valued at £43,550, in the corresponding period of 1921.

Mr. Baldwin, replying to Mr. Bonwick, said that the duty collected under Part II of the Safeguarding of Industries Act on aluminium hollow-ware up to February 23 was £9690.—(Feb. 27.)

German Reparation Dyes

Sir P. Lloyd-Greame, answering Mr. Hope Simpson, stated that no Reparation dyestuffs other than indigo were being sold to any firms for re-sale in this country apart from the general scheme of distribution conducted by the British Dyestuffs Corporation. The supply of German indigotin was requisitioned from Germany under an arrangement between the chief consumers in this country and the British Dyestuffs Corporation, the only British manufacturers of that product. The quantities received were sold to the Corporation at the prices credited to Germany *plus* cost of importation. Under the arrangement the Corporation was delivering against all home orders for synthetic indigo two-thirds British make and one-third German make at an equalised price.—(Feb. 27.)

Sugar-Beet Cultivation

Sir R. Sanders, replying to Mr. Clarry, said that it had been the policy of successive Governments to encourage sugar-beet cultivation in this country, as was shown by the investment of public funds in Home-grown Sugar, Ltd., and by the remission of the Excise Duty on home-grown sugar.—(Feb. 27.)

Insulin Treatment of Diabetes

In reply to Dr. Chapple, Viscount Wolmer said that insulin could not be made available until a supply of known efficiency, potency and safety was attained on a manufacturing scale. Considerable progress had been made by the Medical Research Council in this direction and the successful manufacture in the near future appeared assured. No special Grant-in-Aid would accelerate production at this stage.—(Feb. 28.)

Sugar Duties

Answering Com. Bellairs, Mr. Baldwin said that since the sugar duty was reimposed in 1901, it had been reduced once only, viz., from 4s. 2d. to 1s. 10d. per cwt. in 1908, when the retail price fell by ½d. per lb. The preferential reduction in 1919 of one-sixth of the duty in respect of Empire sugar and the abolition in 1922 of the duty on home-grown sugar were not accompanied by any reduction in retail prices.—(Mar. 1.)

REVIEWS

ORGANIC SYNTHESES. *By* JAMES B. CONANT. *Vol. II. Pp. vii*+100. *New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.*, 1922. *Price* 7*s.* 6*d.*

The appearance of the second volume of this series, which aims at providing absolutely reliable methods for the preparation of organic research materials, will be welcomed by all interested in this branch of chemistry. In the present pamphlet, the methods of preparation of twenty-five compounds, in quantities up to 1 kg., are fully, but concisely described, and as with each the precaution of independent checking in separate laboratories has again been adopted, the repetition of the experiments by other workers is reasonably assured. As before, the compounds are arbitrarily chosen, but a certain number, such as benzyl cyanide, ethyl phenylacetate, phenylacetic acid, etc., group themselves together. Such important materials as ethyl oxalate, hydrazine sulphate, phenylhydrazine, *p*-dimethylaminobenzaldehyde and phthalimide, are also included. In many cases minor but valuable alterations in the previously recorded methods have been effected. As an example of this, the preparation of *p*-nitrobenzoic acid from *p*-nitrotoluene may be quoted, the reaction period having been cut down from about forty hours to one hour.

These volumes cannot fail to be of value to all organic chemists, employed either in academic work or in industry. Moreover, many of the preparations are highly suitable as exercises for students and, in this respect, the notes appended to each should prove extremely useful, exemplifying as they do the great care which must be taken if successful results are to be obtained in practical work of this type. The book is excellently printed and remarkably free from typographical errors. I. M. HEILBRON

A TEXT-BOOK OF INORGANIC CHEMISTRY. Vol. IX. Part 1.—COBALT, NICKEL AND THE ELEMENTS OF THE PLATINUM GROUP. *By* Dr. J. NEWTON FRIEND, Ph.D. *Second edition, revised. Pp. xxv*+367. *London: Charles Griffin and Co.*, 1922. *Price* 18*s. net.*

This volume, the fifth so far published of the series of ten which will constitute the complete Text-book of Inorganic Chemistry, edited by Dr. J. N. Friend, is now in its second edition. A review welcoming the appearance of the volume, and stating that it formed a valuable addition to the existing literature on the subject, has already appeared in these columns (this J., August 5, 1920, 282 R). Most of the printers' errors and inaccuracies that were then noted have apparently been corrected, and a new and important feature is the addition of short but valuable footnotes on the estimation of the platinum metals. In addition one of the tables has been revised. It would be an advantage if some indication of the contents could be provided on the cover.

Organic Chemistry or Chemistry of the Carbon Compounds. *By* Victor von Richter. *Edited by* Prof. R. Anschütz *and* Dr. H. Meerwein. *Translated from the eleventh German edition by* E. E. Fournier d'Albe, D.Sc. *Volume III. Heterocyclic Compounds. Pp. xviii* + 326. *London: Kegan Paul, Trench, Trubner & Co., Ltd.*, 1923. *Price* 25*s*.

It is a sad reflection, but nevertheless a true one, that Richter's Chemie der Kohlenstoffverbindungen is almost indispensable to all whose interest in organic chemistry extends beyond the acquirement of a B.Sc. degree. The appearance of Vol. III, which completes the English translation of the eleventh German edition, published in 1912, will therefore be welcomed by many chemists whose chief regret will be that they have had to wait so long for a book of such importance. The publication of this translation in three volumes, whereas the original appeared in two only, has not been necessitated by additions or alterations: "to meet the urgent demand at the hands of the British and American publics, the second volume was issued in England and in the United States as soon as it could be got out." As each of the three volumes contains its own index, this division is of little importance; in one way it is an advantage, in another, a disadvantage.

The table of contents of Vol. III is more detailed and more clearly set out than that in the original and the whole book is well printed, leaded type being used for the names of the compounds which are described. These are the heterocyclic compounds, classed primarily according to the number of atoms in the closed chain, and secondarily, according to the number of atoms, other than those of carbon, of which the closed chain is composed. It may be imagined, therefore, that parts of the book, such as those dealing with the *azoles* and the *azines* would not be chosen for holiday reading, and even the more interesting sections on pyridine and quinoline derivatives and on the alkaloids can hardly be spoken of as attractive literature. This is not a note of disparagement; as a work of reference, almost in fact a dictionary, its main aim is to give as completely and concisely as possible a summary of the literature of the heterocyclic compounds, and this aim has certainly been accomplished—excluding the publications of the last twelve years. The translator, naturally perhaps, has adopted the same system of numbering the atoms of the heterocyclic rings as that used in the original and which in some cases is different from that employed by the Chemical Society; it is a pity that such unnecessary confusion should exist, as the task of connecting names with formulæ is sufficiently troublesome even on an agreed system.

F. Stanley Kipping

REPORT

Report on the Commercial Situation in Siam, at the Close of the Third Quarter, 1922. *By* T. H. Lyle, *H.M. Consul-General, Bangkok. Department of Overseas Trade. Pp.* 44. *H.M. Stationery Office*, 1923. *Price* 1*s*. 6*d*.

The present Report refers chiefly to the port of Bangkok, through which over 80 per cent. of the foreign trade of Siam passes, and is based upon official statistics for the Siamese official year, 2464 (April 1, 1921–March 31, 1922). It is interesting to note that there are no standard weights and measures in Siam. The customary unit of weight is the tical (=15 grammes), and the unit of currency the silver tical (=2s. 1½d. approx.).

Total imports and exports for the year were valued at £13,958,518 and £17,170,776, respectively. This favourable trade balance is attributable mainly to the sale of a large rice crop at favourable rates and does not indicate the existence of flourishing trade conditions in the country. It is anticipated that sugar will continue to diminish in prominence as an item of Siamese export. Imports from the United Kingdom for the years 1920–1921 and 1921–1922, respectively, were valued at £4,744,623 and £2,480,154, imports from all British Dominions amounting to £9,743,303 in the latter year. It is important to note that the figures do not take account of the considerable volume of United Kingdom goods comprised in imports from Singapore. The competition of countries having low rates of exchange is amongst a number of factors which indicate that the British manufacturer must reduce prices if his pre-eminent position in the market is to be maintained.

The total values of various imports from all sources for the year 1921–1922 were as follows, the share of the United Kingdom being given in parentheses (av. val. of £1=9·58 ticals):—Iron and steel manufactures, £881,556 (£342,711); sugar and molasses, £516,136; kerosene, benzene and liquid fuel, £489,127; beer, wine and spirits, £219,701 (£44,977); oils, other than mineral oils, £162,498; coal and coke, £67,122 (£13,925); metals, £61,040; rubber manufactures, £49,486; dyestuffs, £33,584. Imports of manufactures of iron and steel from the United Kingdom consisted of railroad material, galvanised sheets, bars and sections, and tinplate. Germany is gradually acquiring the trade in wire and wire nails to the exclusion of Belgium, principally owing to lower prices. In enamelled goods, Japan continues to hold first place. Coal from the United Kingdom again appears amongst the imports, largely owing to cheaper rates of freight. It appears that the Siamese Government is still continuing its investigations for petroleum at Muang Fang and other places in North Siam, but no results have yet been made public.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

There has been little or no change in the volume of business passing in the chemical market but a strong undercurrent of opinion that a much brighter tone will shortly be seen. Whether this is the outcome of developments in Germany and the probable stoppage of shipment therefrom in certain articles, or whether it is partly caused by anticipated general improvement in trade, is hard to judge, but probably a combination of both is the true reason. The outstanding feature has undoubtedly been an enormous rise in the price of Carbolic Acid, which in a very short period has doubled, and even at to-day's figure shows signs of further increases.

Acid Acetic, 40% tech.	£22 10s. per ton. Firm tone still maintained. Advance expected.
Acid Hydrochloric	4s.-5s. carboy d/d.
Acid Nitric, 80° Tw.	£25 per ton. Not in much demand on the open market.
Acid Sulphuric	Average national price for Crude Tower Acid 140° Tw. is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton. Fair request for home consumers, with a firmer tone for export.
Arsenic (White)	£70 per ton. Prices nominal and very few parcels available.
Bisulphite of Lime	£7 per ton, packages extra and returnable.
Bleaching Powder	£10 10s.-£11 10s. per ton. No change in position.
Calcium Chloride	£6 per ton. No change.
Copper Sulphate	£26 10s. per ton f.o.b.
Potash Caustic, 88/90%	£29-£30 per ton. No change.
Potass. Bichromate	6¼d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton. Price unaltered and manufacturers are offering more freely than of late, but business has not reached very large dimensions.
Soda Caustic, 76%	£20-£21 per ton. Not in very brisk demand at present.
Soda Crystals	£5 5s. carr. paid. Manufacturers have reduced their prices 5s. ton.
Sod. Acetate	£24 10s. per ton. In better demand with very small quantities available.
Sod. Bicarbonate	£10 10s. per ton.
Sod. Bisulphite Powder, 60/62%	£19-£20 10s. per ton f.o.b. or f.o.r. London.
Sod. Chlorate	Market dull with spot parcels offering at 2⅞d. per lb.
Sod. Nitrite, 100% basis	£30 per ton d/d.
Sod. Sulphide, solid 60/62	£15 per ton. No change.
Sod. Sulphite, Pea Cryst.	£17-£17 10s., 1-cwt. wooden kegs included.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£9 per ton d/d.
Grey, 80% basis	£18 10s.-£20 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£9 10s.-£10 per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 6d. ,, ,, Unrefined. Somewhat lower prices, however, are reported in some quarters.
Wood Naphtha—	
Miscible	6s. 6d. per gall. 60% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£5 per ton d/d.
Brown Sugar of Lead	£38 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 6d. per lb. Market very strong and higher prices are expected.
Crude 60's	3s. 9d.-4s. per gall. Demand still strong.
Acid Cresylic—	
97/99	2s.-2s. 2½d. per gall.
Pale 95%	1s. 11d. per gall.
Dark	1s. 9d.-2s. per gall. Fair inquiry.
Anthracene Paste, 40%	4d. per unit per cwt. Price nominal. No business.
Anthracene Oil—	
Strained	9d.-11d. per gall. Fair inquiry.
Unstrained	8¼d. per gall.
Benzole—	
Crude 65's	1s. 1d.-1s. 1½d. per gall.
Standard Motor	1s. 6d.-1s. 8d. per gall.
Pure	2s.-2s. 6d. per gall. Demand poor.
Toluole—90%	1s. 9d. to 1s. 11d. per gall. Little inquiry.
Pure	2s.-2s. 3d. per gall. Poor demand.
Xylol	2s. 9d.-3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	10½d.-1s. 1d. per gall. Fair demand.
Middle Oil	8¼d.-10d. gall.
Heavy	8¼d.-10d. ,,
Standard Specification	8¼d.-10d. ,,
	According to district. Market strong.
	Good inquiry forward.
Naphtha—	
Crude	9d.-9¼d. per gall.
Solvent 60/160	1s. 6d.-1s. 9d. per gall. Not much business.
Solvent 90/190	1s. 6d.-1s. 7d. per gall. Fair demand.
Naphthalene Crude—	
Whizzed or hot pressed	£9 10s.-£12 10s. per ton.
Drained Creosote Salts	£5-£9 per ton. Supply still short.
Naphthalene Crystals	£17 per ton.
Naphthalene Flaked	£15 per ton.

Pitch, Medium Soft	160s.-172s. 6d. per ton. Market strong. Good inquiry both prompt and forward.
Pyridine—90/140	10s. 6d.-12s. 6d. per gall. Little demand.
Heavy	8s.-9s. per gall. Price still nominal.

INTERMEDIATES AND DYES

Acetic Anhydride	1s. 5d. 100% basis.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 7½d. lb. 100% basis d/d.
Acid Neville & Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb. 100% basis d/d.
Aluminium Chloride—Anhydrous	1s. per lb. d/d.
Aniline Oil and Salts	10d. per lb. naked at works.
Antimony Pentachloride	1s. 1d. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
Dinitrobenzene	11d.-1s. per lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrophenol	£140 per ton.
Dinitrotoluene—48/50	8d.-9d. naked at works.
66/68	1s. 2d.-1s. 3d. naked at works
Diphenylamine	3s. 3d. per lb. d/d.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Metanitraniline	5s. 6d. per lb. d/d.
Meta Phenylene Diamine	5s. 6d. per lb. d/d.
Meta Toluylene Diamine	5s. per lb. d/d.
Monochlorbenzol	£70 per ton.
α-Naphthol	2s. 9d. per lb.
β-Naphthol	1s. 1d. per lb. d/d.
α-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	7d.-9d. per lb., drums extra.
Nitronaphthalene	1s. per lb. d/d.
Naphthionate Soda	2s. 8½d. lb. 100% basis d/d.
Orthonitrochlorbenzol	2s. per lb. 100% basis d/d.
p-Chlorphenol	4s. 6d. per lb.
Paradichlorbenzol	£55 per ton.
Paranitrophenol	1s. 9d. per lb. 100% basis.
Parachloraniline	3s. per lb. 100% basis.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
Para Phenylene Diamine	12s. per lb. 100% basis d/d.
Para Toluidine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid Acetic, 80% B.P.	£46 10s. to £47. Market very firm.
Acid Acetyl Salicylic	3s.-3s. 2d. per lb. Price steadily advancing on the Continent. Raw material also advancing in price.
Acid Benzoic	2s. 3d. per lb. No change. Supplies restricted.
Acid Boric, B.P.	£61 per ton Crystals, £65 per ton Powder, packages in 2-cwt. bags.
Acid Citric	1s. 8d. per lb. Market steady with upward tendency.
Acid Gallic	3s. per lb.
Acid Pyrogallic, cryst.	5s. 6d. per lb.
Acid Salicylic	1s. 9d.-2s. lb. Firm and likely to go higher. Extraordinary variations in prices are recorded, sometimes as high as 3s. per lb.
Acid Tannic	3s. 3d. per lb. Little demand.
Acid Tartaric	1s. 2¾d. per lb., less 5%. Raw material still very firm. Price tendency upward. Demand expected to improve.
Amidol	9s. per lb.
Amidopyrin	12s. 6d.-13s. per lb. Now quoted.
Ammon. Benzoate	3s. per lb. for good makes.
Ammon. Sulphocyanide	2s. 6d. per lb.
Barbitone	14s. per lb. Higher.
Benzonaphthol	5s. per lb. Not much demand.
Bismuth Salts	Price per lb. for cwt. lots are as follows: — Carbonate 13s., Citrate 11s. 7d., Nitrate Cryst. 6s. 11d., Oxide 14s. 5d., Salicylate 10s. 5d., Subchlor 12s. 8d., Subgallate 9s. 6d., Subnitrate 11s.
Bromides	Market unsettled. Tendency to higher prices owing to possible difficulties in obtaining Continental supplies.
Calcium Lactate	2s. per lb. Firm and steady.
Chloral Hydrate	3s. 9d.-4s. per lb., according to quantity and holder.
Ethers (Methylated)	Makers have announced an all round reduction of 1d. per lb. in consequence of the lower price in force for industrial methylated spirit.
Formaldehyde, 40%	£90-£92 10s. per ton.
Guaiacol Carbonate	8s. per lb.
Hexamine	4s. per lb. Continental prices still rising.
Homatropine Hydrobromide	30s. per oz.
Iron Ammon. Citrate	B.P. 2s. 5d. lb. Green 3s. 1d. lb. } Market quiet.
Magnesium Carbonate—Light Commercial	£37 per ton.
Magnesium Oxide—Light Commercial	£85 per ton.
Heavy Commercial	£28 per ton.
Menthol	37s. per lb., less 2½% for original cases. Small quantities 37s. 6d. nett.
Methyl Salicylate	2s. 3d. per lb. Steady demand. Price firm.
Methyl Sulphonal	13s. per lb.
Mercurials	English makers have reduced prices 2d. per lb. for all salts.
Paraformaldehyde	3s. 6d. per lb. present value.
Paraldehyde	1s. 6d. per lb. Unchanged.
Phenacetin	5s. 3d. per lb. Slightly higher and distinctly firmer.
Phenazone	7s. per lb. Price fully maintained.
Phenolphthalein	4s. 9d. Easier.
Potass. Bitartrate—99/100% (Cream of Tartar)	98s.-100s. per cwt. less 2½% for ton lots. Same tendency as with Acid Tartaric.

Potass. Iodide	15s. 8d. per lb. for cwt. lots. Cases free. Good market.
Potass. Permanganate ..	9d. per lb. Spot holders are unwilling to sell below.
Quinine Sulphate ..	2s. 3d.-2s. 4d. oz. Steady market.
Salol	2s. 4d. per lb. Demand limited, value steady.
Sod. Benzoate	2s. 3d. per lb. still quoted.
Sod. Citrate—P.B.C. ..	2s. per lb.
U.S.P. ..	2s. 3d. per lb.
Sod. Hyposulphite—Photographic	£15-£17 per ton, according to quantity.
Sod. Potass. Tartrate (Rochelle Salt) ..	82s. 6d.-85s. Fairly good demand.
Sod. Salicylate	2s. 1d.-2s. 3d. per lb. A further advance in price is probable.
Sod. Sulphite, Anhydrous	£27 10s.-£28 10s., according to quantity; f.o.r. London, drums included.
Tartar Emetic ..	1s. 4d.-1s. 6d. per lb.
Thymol	19s. per lb. for first quality product.

PERFUMERY CHEMICALS

Amyl Acetate	2s. 3d. per lb.
Amyl Butyrate	8s. ,,
Amyl Salicylate ..	3s. 3d. ,,
Anethol (Melting point 21°/22° C.)	4s. 6d. ,,
Benzyl Acetate (from chlorine-free Benzyl Alcohol)	3s. ,,
Benzyl Alcohol free from chlorine	3s. ,,
Benzaldehyde, free from chlorine	3s. ,,
Benzyl Benzoate. 19·5° C.	3s. ,,
Cinnamic Aldehyde, 98/100%, Natural ..	14s. 9d. ,,
Coumarine	12s. 6d. ,,
Citronellol	22s. 6d. ,,
Citral, 100%	9s. 6d. ,,
Ethyl Phthalate ..	4s. 3d. ,,
Eugenol, 100%	11s. ,,
Geraniol (from Palmarosa)	30s. ,,
Geraniol	5s. 6d.-12s. 6d. per lb.
Heliotropine	5s. 9d. per lb.
Iso Eugenol	18s. 6d. ,,
Linalol ex Bois de Rose ..	21s. ,,
Linalyl Acetate	22s. 6d. ,,
Methyl Benzoate ..	8s. 6d. ,,
Musk Xylol	8s. 9d. ,,
Phenyl Ethyl Acetate ..	10s. ,,
Phenyl Ethyl Alcohol ..	17s. 6d. ,,
Rhodinol	45s. ,,

ESSENTIAL OILS

Anise Oil, Red Ship Brand	2s. 1d. per lb.
Bourbon Geranium Oil ..	26s. 6d. for shipment.
Cananga Oil, Java ..	9s. Firm.
Cinnamon Oil Leaf ..	4d. per oz.
Cassia Oil, 80/85% ..	8s. 3d.
Citronella Oil—	
Java, 85/90% ..	3s. 9d.
Ceylon	3s. 6d.
Clove Oil	8s. 3d.
Eucalyptus Oil, 70/75%	1s. 8d.
Lavender Oil, Mont Blanc 38/40%	12s. 6d.
Lemon Oil, spot ..	3s. New crop for shipment 2s. 11d.
Orange Oil, sweet, spot	10s. New crop for shipment 10s. 6d.
Otto of Rose Oil—	
Anatolian	24s.
Bulgarian	26s.
Palma Rosa Oil ..	17s. 6d.
Peppermint Oil—	
English, Mitcham ..	80s.
Wayne County ..	13s.
Japanese	6s. 9d.

TRADE NOTES

Chemical Trade in British Malaya

The following statistics show the trade in chemicals, drugs and dyes of Malaya during 1921 and 1922: —

	Imports		Exports	
	1921	1922	1921	1922
	£	£	£	£

The exports go mainly to Siam, Borneo, French Indo-China and the Dutch Islands in the Archipelago. Imports of acetic acid used for coagulating latex amounted to 48,660 gallons in 1921 and 387,594 galls. in 1922.—(*Bd. of Trade J., Mar.* 1, 1923.)

International Gas Exhibition in Holland

The municipal authorities of Amsterdam are organising an International Gas Exhibition to demonstrate the use of gas for industrial purposes in metal and chemical works, food preserving factories, central heating systems, etc., and for household and scientific use. British firms may inspect the rules of the Exhibition at the Department of Overseas Trade, and a few copies are available for loan to firms unable to inspect the rules in London. (Ref. 7808/F.B./G.P.)

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, MARCH 16, 1923 No. 11

EDITORIAL

INTEREST in the new element, or elements, continues unabated and investigation of the results announced is proceeding actively in several laboratories. Through the kind offices of Professor Biilmann, vice-president of the International Union for Pure and Applied Chemistry, we are able to print, in this issue, a most interesting paper by Professors Coster and Hevesy, whom we invited some little time ago to send us a communication on their discovery of hafnium. An interesting sidelight on the discovery is provided by the note (on page 276), very kindly supplied by Dr. E. B. R. Prideaux, on "New Zealand Ironsand," the source, it will be remembered, from which Dr. Scott obtained the oxide of his new element. The work now being done at Copenhagen is no longer confined to the X-ray analysis of minerals containing the new element, and in last week's *Nature* there is a letter describing the lines which appear in the ordinary optical spectrum of hafnium. Messrs. H. M. Hansen and S. Werner, who make the communication to *Nature*, state that none of these lines correspond with those ascribed by Urbain to the spectrum of celtium and point out that some of the most prominent hafnium lines have been present as weak lines in zirconium spectra measured by earlier investigators, particularly Bachem in 1910. It is of interest to note that a full account of the hafnium spectrum, with measurements of the wave-lengths of the characteristic lines, will be issued shortly.

* * *

The therm, after undergoing what was claimed to be universal condemnation, has now been rehabilitated. The Committee appointed by the Board of Trade to report on the method of charging for gas on the thermal basis has recommended that the system should be continued, but adds that the public should be provided with indications to show the relation of the old system of charging by volume, to the new one of charging by calorific value. To the unprejudiced observer, the fact that there has been a public inquiry into the application of such an admittedly logical system of charging for gas—gas, be it noted, that is of no value nowadays for direct lighting purposes—is almost ludicrous. We are glad to note that at least one large daily paper predicted that the therm would be "acquitted with a caution." The confusion in the public mind has been undoubtedly due to the introduction of the new system without adequate explanation, at a time when the cost of producing gas was actually higher. An interesting point in the report is the conclusion that the control over the calorific value of the gas supplied is adequate in London, but the committee is not satisfied that tests are sufficiently frequent in other areas, and therefore recommends that maintenance of the standard calorific value should be ensured by the use of continuously recording calorimeters. With regard to the question of carbon monoxide in coal gas, the committee states that this is outside the terms of reference, but recommends that, as gas is now in many cases supplied under an increased pressure, precautions should be taken to see that the fittings are properly adjusted.

Owing to the prominence with which the gas industry has been brought before the public of late, some interest has been taken in the origin of the word "gas." We understood that the word was invented by the Dutch chemist, J. B. Van Helmont, somewhere in the 17th century, and that he derived it either from the Greek word "chaos," or from the Dutch word "geest," spirit, but this has been doubted. We should be glad if our readers would enlighten us on this point.

* * *

We commented recently on Professor Lowry's article on the Uniqueness of Hydrogen, and are not surprised that this and a subsequent one on a Method of Representing Co-ordination have received a good deal of attention. Two or three years ago Langmuir showed many diagrams of possible constitutions of chemical compounds based on the octet theory, and other workers have contributed to this study; but we do not call to mind any chemist who has applied the relation of the positive electricity on the nucleus to the negative electricity on the outer sphere of the atom with such care and boldness as Professor Lowry. We shall publish shortly some further contributions from him and it seems quite likely that the field of investigation he now enters, is a considerable tract of territory which will keep him and his associates busy for a long period. All chemical combination seems to be due to the mutual attraction between the positive nucleus of one atom and an electron which belongs wholly or partly to another atom. If we understand Professor Lowry's views aright he draws a sharp line of distinction between (*a*) the case of a nucleus, with, say, 7 units of positive electricity surrounded by 8 electrons and its attraction for a nucleus with 9 units of positive electricity surrounded by 8 electrons, and (*b*) the case of two nuclei with 4 and 6 units of positive electricity respectively, and partially surrounded by 2 electrons each, but held together by their common attraction for 6 electrons lying between them and cementing them together. The one is comparable to the companionship of husband and wife, the other to the companionship of the two wives of a Turk or a Mormon. If the wife is considered as a lost rib the analogy is more exact, but the comparison must not be applied too closely; Lowry rather ignores the importance of the Turk as an element in the family; in the case of units of electricity, at any rate, attractiveness is not a function of mass.

It is not clear that anyone before Lowry has paid attention to the units of positive electricity as factors explaining the binding together of various organic compounds, and we feel sure that our readers will derive considerable satisfaction from the articles which are shortly to appear.

THE PRODUCTION OF LEAD IN BRITAIN

By PROF. H. LOUIS, M.A., D.Sc.

Lead ores occur abundantly, and are widely distributed throughout the greater part of Great Britain—more so, indeed, than any other mineral of similar economic importance. Taking the line of Secondary rocks which crosses England diagonally from about Whitby to about Lyme Regis as the dividing line between the geologically more recent and more ancient areas, between the flatter and the more mountainous portions, there is hardly a county within the latter area in which lead ores have not been met with. Lead ores in this country are essentially characteristic of the Palæozoic rocks, as may be seen from the following table of the distribution of the more important deposits:—

Metamorphic.—Greater part of Scotland.
Cambrian.—Merionethshire and other portions of North Wales.
Cambrian-Ordovician.—Anglesey, West Carnarvonshire and some other portions of North Wales; Lake District.
Ordovician.—Scotland (Leadhills and Wanlockhead district); Central Wales; Shropshire (Minsterley and Shelve district).
Silurian.—Scotland (Lanarkshire and Kirkcudbrightshire); Central Wales; Denbighshire and Flintshire; Anglesey.
Old Red Sandstone.—Caithness; Orkney.
Lower Devonian.—Cornwall (New Quay district).
Middle Devonian.—Devonshire (Combe Martin); Cornwall (Liskeard, etc.).
Upper Devonian.—Cornwall (Liskeard, etc., Tavistock district).
Carboniferous Limestone.—Cornwall (Tavistock), Devonshire (Teign Valley), Somersetshire (Mendips), North Wales (Denbighshire), Pennine Chain (Northumberland, Durham, Yorkshire, Derbyshire), Northumberland.

This list shows clearly the wide distribution of lead ores through all portions of the Island in which Palæozoic rocks occur. No one knows with any definiteness either the primary source of these lead ores or the reason why they are always found in the older rocks, but the fact is very obvious.

In all these places lead ores are found in fissure veins frequently accompanied by a small amount of faulting, the veins being vertical or steeply inclined, so that well-marked outcrops are the rule. In some of the limestone districts the ore also occurs in flats and pipes occupying joints in the limestone, but in every case closely connected with fissure veins.

There is only one primary ore of lead—namely, galena. Sometimes this ore holds up comparatively unchanged or covered only with a thin crust of sulphate up to the grass roots, and in many places masses of detached ore or shoad-stones, as the miner calls them, of galena similarly encrusted are found in the overlying alluvial, ranging in size from fragments the size of a pea up to boulders weighing several hundredweights. In other cases the galena has undergone oxidation, which may extend for some distance down the vein, producing a series of oxidised lead ores, the more important of which are the sulphate, carbonate, phosphate and arsenate, the characteristic yellow and green shades of the latter having given rise to the Derbyshire miners' name of " linnets " for such ores. The reasons why these chemical changes have occurred in some veins and not in others is somewhat obscure, but the chemistry of the changes is obvious enough, and it may be noted that these oxidised ores are more plentiful in limestone than in slate country. All lead ores carry silver, the amount of which is very variable. Thus, in the Weardale and Alston districts the ore runs about 6 oz. of silver to the ton ; in Yorkshire and Derbyshire, 1 oz. to 2 oz. ; in Shropshire, 2 to 3 oz. ; in Cardiganshire and Montgomeryshire, 3 to 4 oz. ; Flintshire, 5 to 6 oz. ; Denbighshire, 3 to 4 oz. ; Somersetshire, about 2 oz. ; in Wanlockhead and Leadhills, 3 to 5 oz. ; the blue-stone of Anglesey carries from 5 to 15 oz. ; the lead ores of the Isle of Man, 30 to 40 oz. ; of Cornwall and Devon, 40 oz. ; whilst some mines like Beer Alston are said to have carried up to 45 oz. ; in the Lake District lead veins low in barytes carry 6 to 8 oz. ; those rich in barytes, 25 oz. or more per ton of ore. The average for the whole of Great Britain may be taken as between 4 and 5 oz.

All lead ores have this characteristic in common—that they are easily reduced, simply sprinkling any of them upon an ordinary fire being sufficient to cause reduction of a large portion of the lead. The galena is reduced by being partially oxidised, the oxide or sulphate so formed interacting with some of the unoxidised galena. Oxidised ores appear to be mostly reduced by simple contact with the glowing carbon, especially in the presence of a base such as would be furnished by wood ashes. The elementary metallurgy of lead is therefore exceedingly simple, and the reactions above indicated all take place at quite low temperatures.

Lead in Ancient Times

Under such conditions it is inconceivable that lead should not have been one of the earliest metals to be discovered by the primitive races of mankind, but its use to primitive man was no doubt limited. He would be interested merely in such metals or alloys as were capable of taking a cutting edge and would have no use for a soft material like lead. The cave man, or even his immediate successor, would have as little use for sheet lead for roofs as for lead pipes for water, and apparently it was only at a relatively late stage that the use of leaden missiles, such as sling stones, appears to have occurred to him. Even in the centre of our ancient civilisation the use of lead is relatively recent. Leaden objects have been found at Nineveh and were used by the Assyrians about 900 B.C. ; Schliemann found leaden objects at Mycenae and Tiryns, and the Greeks are known to have used lead freely.[1]

In Britain very few examples of the use of lead in prehistoric times have been met with. Lead has been quite often found as an ingredient in bronze, in some cases up to about 10 per cent., but whether this admixture was accidental or should be looked upon as a deliberately added adulterant is doubtful. Sir John Evans[2] mentions that two swords found near Tosson, in the parish of Rothbury, had pommels of lead ; he also points out[3] that a bronze celt mould has been found with a little lead adhering to it, and that " several socketed celts made of lead have from time to time been found." He suggests that these may have been used as patterns for casting from, in the same way that white metal patterns are used in the foundry to-day.

In the times immediately preceding Cæsar's invasion of Britain there is no evidence of the production of any lead in this country. Some of the writers of this period mention Britain as a producer of silver, and it is difficult to see how this could have been obtained save from argentiferous lead ores (except, perhaps, from certain of the Cornish and Devonshire mines), though it is of course possible that the silver may have been extracted without recovering the lead associated with it, in the metallic state. Strabo,[4] writing about the time of Cæsar, says that Britain produces gold, silver and iron. We learn from him that, according to Posidonius, the Cassiterides produced tin, and that from the Britannic Islands this metal is carried to Marseilles.[5] His own statement is that the Cassiterides are ten in number ; of the metals they have lead and tin.[6] Cæsar[7] himself, after his second invasion, mentions the production in Britain of tin and iron, but makes no reference to lead. It is not until a century later that the classical writers speak of the production of lead in this country. Tacitus, 97 A.D., is somewhat vague, saying only that Britain produces gold and silver and other metals,[8] but Pliny the elder, in his History written twenty years before the latter date, makes a very definite statement in the oft-quoted passage,[9] in which he says that in Britain lead occurs in the upper crust of the earth, and so plentifully that a law had been passed restricting its production. There seems little doubt that by this time Britain was not only an important producer of lead but also exported this metal on a considerable scale. It is most probable that there was no true mining for lead before this time ; all the lead smelted in pre-Roman times and in the earlier periods of the Roman occupation will have been smelted from float ore, either picked up on the surface or obtained by washing the surface soil in the lead mining districts, where the mineral occurred in large quantities. That the Romans lost no time in turning this mineral wealth to account is evident from the fact that in the Mendip Hills a pig of lead has been found bearing the name of the Emperor Claudius, date A.D. 49, and thus only six years after their occupation of Britain. Fifteen years later they were smelting lead in Flintshire. In succeeding centuries they must have exhausted a large portion of the float ores and commenced true underground mining in various places. In the mines of the Mendip Hills Roman lamps made of lead have been found, and there is ample evidence of actual mining by the Romans. Leaden objects of Roman age have been found in comparative abundance ; pigs of Roman lead have been found in various parts of the country, not only in the mining districts but also along the great trade routes in such counties as Norfolk and Sussex, a fact which indicates clearly that this lead was intended for export. Dr. Percy points out that some of these pigs are marked "*Ex Arg.*" or desilverised. It is, of course, well established that the Romans were familiar with the process of extracting silver from lead by cupellation long before their arrival in Britain, and it is highly probable that they worked the lead ores not only for the sake of the lead but also for the sake of the silver which they contained ; and there is no doubt but that they knew how to recover both of these metals. As has been shown, all British lead ores are comparatively poor in silver, but it is well known that when an argentiferous lead ore weathers a great deal of lead may be dissolved away from it, probably as a chloride or as an organic compound, while the silver is not thus affected, so that the ore is naturally enriched by the process of weathering. Thus a boulder of float ore picked up in Weardale yielded some 120 oz. of silver to the ton, whereas the ordinary ore, as mined in depth, only contains 3 oz.

[8] Agricola, Cap. XII.

Among the leaden articles belonging to this period are hammered plates, pipes, coffins, cists, and other vessels. At Corstopitum a hoard of Roman gold coins was found enclosed in a leaden receptacle. A lead tablet with an inscription was found amongst the Roman remains at Lydney.[10] The Romans also used articles made of pewter, an alloy of lead and tin, though this did probably not come into use until a relatively late period. Thus, at Minton, Roman pewter has been found associated with coins dating from 360 to 410 A.D.[11] In all probability this pewter was produced by deliberate mixing of the two metals, the Romans being well acquainted with the use of such an alloy for soldering purposes. It is, however, just possible that it may have been produced in the first instance from a natural mixture of the two ores found together in alluvials in Devon or Cornwall. The author has recorded such an occurrence in the Far East, where he found the Chinese smelting a natural mixture of lead and tin ores obtained by washing certain alluvials in the State of Patani in the northern part of the Malay Peninsula.[12] Before the Romans retired from Britain lead mining and smelting must have been a firmly established industry, and there is no reason to doubt that it continued to exist even through the troublous times that followed their departure. Lethaby is of the opinion that "There is just enough evidence to show that the use of leaden coffins was continued by the English after they had superseded the Romans."[13]

The Venerable Bede, in his History of the Church of the English People, says that Britain is rich in veins of the metals copper, iron, lead and silver :[14] "*Venis metallorum, aeris, ferri et plumbi et argenti fecunda.*" It is interesting to note that in Alfred's translation of this passage, circa 900 A.D., we find the first use in English of the word "leade" (lead), which is apparently derived from the Frisian. Further on Bede states that Eadberct, Bishop of Lindisfarne, took the old thatch off the church at that place, which had originally been built by Finan, and covered the roof and sides with sheets of lead. The date of this must have been about 680 A.D. Wilfrid in the same way covered the decayed roof of the church of York with pure lead and glazed the windows.[15] In neither case does the description read as though the use of lead for that purpose were anything of a novelty.

Lethaby mentions a leaden book cover of Saxon work with an inscription of Aelfric's Homilies. Lead mines were evidently in operation at the time of the Norman invasion, for the "Domesday Book" records the existence of lead mines "*plumbaria*" in Derbyshire. From the earliest times of the Norman Conquest onwards lead was in ordinary use for coffins ; numerous leaden fonts and leaden church ornaments are known through many centuries, so that lead production in Britain must have been active and continuous. To quote Lethaby[16] again :—" In Saxon England lead was a staple commodity for export and used in great quantities at home. . . . During the Middle Ages it was largely applied to many purposes. . . . England was still the best esteemed source of supply."

Lead Smelting

Seeing that underground mining was introduced by the Romans, they must have been quite familiar with crude methods of breaking up and washing the ore. Possibly at first they confined their underground operations to following up ribs of solid galena, but they no doubt soon mined ore which required some form of dressing, and we know that they were familiar with a certain number of primitive methods of attaining this object; so that it may be assumed without much hesitation that they prepared fairly clean ore for smelting purposes. As to the methods employed up to the late Middle Ages for smelting lead ores, we have no definite knowledge; but, as has already been pointed out, this is one of the easiest of all smelting operations and was certainly well within the capability of the early British metallurgists, who were evidently highly skilled workers in bronze long before the advent of the Romans. How simple the operation of lead smelting may be made can be gathered from the following extract from *The Useful Metals and their Alloys*, by Robert Oxland and other writers (1861) :[17] " If a western backwoodsman wants shot or bullets, he will kindle a fire in a hollow tree or an old stump of a tree, place some galena on the charred wood and melt it down. After cooling, he finds the metal at the bottom of the hollow. Formerly lead was smelted in log-furnaces, in Missouri . . . a rude kind of square furnace, constructed of logs or stones. The front wall of such a furnace is about eight feet wide and seven feet high. The hearth in the bottom of the interior is about two feet wide, eight feet long, and ten or twelve inches high, forming ledges or boshes with the side-walls one foot in width. The arch in front, which admits air into the furnace, is about two feet high and wide, and is temporarily shut by stones, clay or brick. A basin in front of the furnace receives the fused metal, from which it is ladled into the pig-moulds. The operation in this furnace was simple. A layer of heavy logs was placed horizontally in the bottom; then billets of split wood were set upright, and these covered with galena; the top of the ore was covered by small wood. A fire kindled in the front arch will char the lower parts of the wood first, and by the time the heat is conveyed to the ore sufficient for melting, the hot charcoal below will expel sulphur and precipitate the metal, which flows out as it is formed. One heat requires twenty-four hours, after which the furnace is cooled and the ashes removed; then it is charged anew. About 50 per cent. of metal is thus obtained from the ore. The ashes which remain contain much metal, and are subjected to a second smelting in the ash-furnace."

" Bolehills "

It is obvious that such crude metallurgical appliances are well within the capacity of a primitive race, and it is equally evident that few traces of their existence are likely to have survived. The most evident indication we have of ancient smelting methods is in the discovery of the so-called balehills or bolehills in certain of the lead-mining districts. There is some doubt as to the origin of the word, but it is now generally referred to the old English " bole," meaning a blazing pile. Sir John Pettus, in his *Fodinae Regales*, says, " Boles or Bolestids are places where in ancient times (before smelting mills were invented) the miners did fine their lead." These bolehills have been referred to by various writers. Thus, Bishop Watson, in his *Chemical Essays*, writes :—" There are several places in Derbyshire called Boles by the inhabitants, where lead has been anciently smelted, before the invention of moving bellows by water. These places are discovered by the slags of lead, which are found near them; there is no certain tradition concerning the manner in which the ore was smelted at these boles; it was, probably, as simple as that of the Peruvians, for in Derbyshire, as well as in Peru, they seem chiefly to have relied upon the strength of the wind for the success of the operation, the boles being always situated upon high grounds, and mostly upon that side of a hill which faces the west. This situation was not fixed upon without design, since the wind blows in England, in the course of a year, near twice as many days from that quarter as from any other." And Dr. Joshua Childrey, in his *Britannica Baconica*, describes them as follows :—" The lead-stones in the Peak lye but just within the ground next to the upper crust of the earth. They melt the lead upon the top of the hills that lye open to the west; making their fires to melt it as soon as the west wind begins to blow; which wind by long experience they find holds longest of all others. But for what reason I know not, since I should think lead the easiest of all metals to melt, they make their fires extraordinary great." These bolehills are by no means confined to Derbyshire, but are known also in other lead-smelting districts, as, for instance, at Wolsingham and Stanhope, in Weardale.

THE GROWTH OF PLANTS

By PROF. E. E. C. BALY, C.B.E., M.Sc., F.R.S.
The University, Liverpool

Dear Sir,—I am more than pleased to accept your invitation to reply to Mr. White, and to offer him a helping hand in the difficulties in which he finds himself. Those difficulties are, perhaps, shared by others whose enthusiasm for plants, with their infinite variety of form and colour, is somewhat chilled by the formal and austere atmosphere associated with a scientific communication in the journal of a learned society. The charm of Mr. White's letter has appealed to me, and I may confess at once to a very keen appreciation of the honour that has come to me in that the work has been deemed worthy of record in latin hexameters. Such honour comes to few men, and fewer still perhaps appreciate it at its full value. The years I spent at Aldenham under John Kennedy, one of the finest and most inspiring of headmasters, taught me to be one of those few.

I will endeavour to explain what Professor Heilbron and I believe to be the process which takes place in the living plant. In the first place there is the well-known process whereby formaldehyde is burnt with oxygen to give carbon dioxide and water, with the evolution of a large amount of energy, the equation being $CH_2O+O_2=CO_2+H_2O+130{,}000$ calories.

The reverse process, namely, the production of formaldehyde and oxygen from carbon dioxide and water, is bound to take place provided that sufficient energy is available, the reaction being highly endothermic. It is impossible to realise the process by the ordinary methods of heating, etc., owing to the very large amount of energy necessary. It is, however, possible by the use of light energy to bring the reaction about, since carbonic acid has the power of absorbing ultra-violet light of very short wave-length, and without discussing in detail the energy quantum theory it is established by this theory that the energy thus absorbed is just the right amount to stimulate the reaction. We have proved this fact by a variety of methods and have demonstrated in several ways that formaldehyde is produced from carbonic acid by the action of ultra-violet light.

We have also proved in more than one way that if the carbonic acid is in combination with a visibly coloured basic substance the formaldehyde is produced when the compound is exposed to visible light. The importance of this lies in the fact that it explains the function of the chlorophyll in the leaves of the plant, since chlorophyll forms a compound with carbonic acid and this compound gives formaldehyde on exposure to sunlight. The energy relations of this process are more complex since there are present four pigments, chlorophyll A, chlorophyll B, carotin, and xanthophyll, and all these have their own *rôle* in the four component equilibrium which is both chemical and photochemical. This complexity, however, does not alter the fact that the chlorophyll combines with the carbonic acid, and on exposure to sunlight gives formaldehyde.

The second point is one of considerable interest, for the formaldehyde molecule when first formed by this photochemical method is not in the same condition as the ordinary formaldehyde molecule and contains far more than the normal amount of energy. This highly reactive formaldehyde does not, as is usually the case, lose its excess of energy and change into the ordinary form, but instantaneously undergoes chemical reaction. If no substance is present to combine with this active formaldehyde, it polymerises at once into sugars which are hexoses and have the general formula $C_6H_{12}O_6$. These sugars are perfectly definite entities for we have succeeded in preparing their pentamethyl derivatives. Mr. White says we have made a syrup which may be a sugar but in saying this he understates what we have done. Our syrup certainly contains sugars which have been definitely established to be hexoses, and therefore we know far more about it than is suggested by the words "formose whose composition is unknown." We have even more information than this for we have found some evidence that the synthesis goes beyond the simple sugar stage and that more complex bodies are formed of the nature of polysaccharides. Since this is actually the case in the living leaf it is by no means extraordinary that we should find the same process in our experiments.

Mr. White seems also to be unaware of what we have done on the nitrogen side of the problem. It is known that plants absorb nitrates from the soil, and that as a result nitrates or nitrites are present in the leaf. It has further been found that when the leaves are kept in the dark the nitrates or nitrites are equally distributed throughout the leaf, but that these salts disappear if the leaves are exposed to light when chlorophyll is present. In an etiolated leaf where chlorophyll is absent these salts are unaffected by light. We have found that, whereas freshly synthesised formaldehyde in the absence of salts polymerises to give sugars, if a nitrate or nitrite is present the formaldehyde preferentially combines with it to give formhydroxamic acid, and that this acid then combines with more of the active formaldehyde to give more complex compounds which I will deal with later. Further, when the formaldehyde is produced at a greater rate than can be utilised by the nitrate or nitrite and the first synthetic product, formhydroxamic acid, the excess polymerises to form sugars.

These observations seem to be of some importance for three reasons. In the first place, they explain the disappearance of the nitrate or nitrite from chlorophyll-bearing leaves in sunlight. In the second place, they prove that many of the nitrogen compounds present in plants can be directly synthesised from carbon dioxide, water, and a nitrate or nitrite, since we ourselves have made many of these compounds in this way. In the third place they explain the simultaneous formation of sugars and nitrogen compounds in the living plant, for it is known that there is never present sufficient nitrite to react with all the active formaldehyde which is being produced by the aid of the chlorophyll.

To turn to the nitrogenous products themselves we have found that when freshly synthesised formaldehyde acts on a nitrite two classes of compounds are formed, namely, amino acids and nitrogen bases of the type of piperidine, pyridine, pyrrole, glyoxaline, etc. Many of these bases react with the amino acids to give the so-called substituted amino acids and in our experiments we have found evidence of as many as eight of these complex compounds, although we have not, as yet, been able to identify them. The condensation of the substituted amino acids to give a protein is but one stage further, and here again we have some evidence that bodies of greater complexity than the substituted amino acids can be synthesised in the laboratory by the action of light, starting from carbon dioxide, water, and a nitrite or nitrate.

Those nitrogen bases which do not condense with the amino acids combine with more formaldehyde to form complex bodies of alkaloidal nature, and I am inclined to believe that the alkaloids are produced from those bases which have not the power of condensing with the amino acids. They form the final end products of the bases which are rejected in the direct protein synthesis.

The question may well be asked as to how we can explain the great variety of alkaloids found in the vegetable kingdom and the constancy in quantity and nature of the alkaloids in a given plant. We have found that the course of the photosynthesis of nitrogen compounds is dependent to a remarkable degree on the conditions. The amino acid synthesis is apparently not altered but the nature of the bases and the alkaloids produced seems to vary very decidedly with the alkalinity of the solution, and thus it may be suggested that each type of alkaloid-bearing plant has a constant alkalinity of its own in its chloroplasts or photosynthetic cells.

Mr. White appears to find an element of insecurity in our experiments on the action of active formaldehyde on ammonia, in view of Stas' observation that it is very difficult to free ammonia from complex organic bases. I hasten to bring comfort to him in his anxiety, for we were fully aware of this well-known fact, and I give him my assurance that the most rigid tests failed to indicate the presence of any such base in the ammonia we used. After the ammonia had been saturated with carbon dioxide in the dark, again no trace of any complex base was found, but after this solution had been exposed to ultra-violet light the presence of complex bases was readily detected.

There are several other points of great interest in Mr. White's letter, and to one of his questions I hesitate very much to reply, namely, whether the chemicals make the plant or the plant makes the chemicals. One's views on this seem to me, after some discussion with my friends, to depend on how one was brought up. A morphological botanist inclines to the latter view, but I wonder whether he is right. Photosynthesis seems to be common to very many of the lowest forms of life and radiant energy must be accepted as the oldest fact of this world of ours. For my own part, rightly or wrongly, I hold the view that photosynthesis is the real driving force behind all life and that the plant is the living mechanism developed from photosynthetic beginnings. In short, I venture to believe that the chemicals make the plant. It is perfectly true that each plant has certain inherited characteristics, by which the production of certain groups of compounds is determined. I have already written of the profound influence that a variation in alkalinity has on the course of the photosynthesis. Might not a similar simple cause influence the other processes of the plant to which so much of what Mr. White writes is due? Speaking as a very humble philosopher I do not think that these differences between different plants need influence our views on the main question.

Now, Sir, this is a very long letter, but I have been led into it by Mr. White's desire for information. I have done my best to be as lucid as the subject allows me, and I trust, too, with all my heart that I am as modest as Dr. Benjamin Franklin could have wished when I say that we claim to have achieved little beyond a simplification. The production of active formaldehyde, sugars, starches, celluloses, amino acids, proteins, and alkaloids is merely a question of energy. When the right amount of energy is given to carbonic acid it is converted into active formaldehyde and oxygen, the latter being transpired into the air again. The former, in the presence of small quantities of a nitrite, reacts to give all the above compounds, every stage of the synthesis being accompanied by a loss of energy. Each separate series of reactions is one of most attractive simplicity, there being no need for the use of the condensing agents which are the tools of the organic chemist when he is synthesising his more complex compounds. The function of these tools is to supply the energy necessary to activate his reactant molecules, and since the whole of the energy in the case of the plant is gained from sunlight in the very first step, namely, the formation of the active formaldehyde from the carbonic acid by the agency of the chlorophyll, the need of agents to supply energy at any later stage vanishes. Although these results in themselves may mark an advance it is the simplicity of the whole that seems to be so important, for it leads one to believe that the vital processes of the higher animals are equally simple and so, perhaps, it may be that the chemistry of their derangement or disease is simple, too.

ON THE NEW ELEMENT HAFNIUM

BY DR. D. COSTER AND DR. G. HEVESY

While the great majority of the elements exhibit conspicuous differences in their chemical behaviour we find as we proceed from hydrogen to uranium, that we suddenly meet a group of chemically closely related elements, the so-called rare earth group, the members of which exhibit so close a resemblance in their chemical properties that their separation encounters great difficulties.

Why does the normal sequence of the elements in the natural system get interrupted through the sudden appearance of the rare earth group? This question could be first answered by the quantum theory of the atomic structure proposed by Bohr. Starting from Rutherford's nucleus atom and the so-called quantum theory of radiation, he has shown that what we call the atom's chemical properties are determined by the number and the arrangement of the electrons of the atom and chiefly by the number and arrangement in the outermost group of electrons. When proceeding from hydrogen to uranium in general we meet appreciable differences in the outermost group of electrons of two neighbour elements, hence the marked difference in the chemical behaviour of these elements. It has been shown, furthermore, by Bohr that we have to encounter at a certain place in the periodic table a group of elements, the members of which only show differences in the constitution of the deeper lying electron groups of their atoms. To such differences in the inner groups correspond only small differences in the chemical behaviour, hence the great similarity in chemical behaviour of the elements within the group of the rare earth elements.

According to Bohr's theory this successive change in the inner groups of electrons happens in the interval between lanthanum (57) and lutetium (71). The element of atomic number 72 however, should, according to the theory, already show in the constitution of the outermost electron group of its atoms differences from the foregoing one—*i.e.*, the element 72 should exhibit properties entirely different from those of the rare earth elements and be a proper analogue of zirconium.

In 1911 Urbain detected the presence of several unknown spectral lines in a preparation of rare earth elements, and, based on this evidence, and on certain measurements of the magnetic properties of his preparation, he announced the discovery of a new rare earth element, celtium. About half a year ago, by investigating Urbain's preparation, using Moseley's method of X-ray spectroscopy, Dauvillier found two exceedingly faint lines in the region where the characteristic X-ray lines of the element 72 should be expected, and announced on the basis of this measurement that celtium is identical with the missing element of the ordinal number 72. This announcement could not be reconciled with Bohr's theory. To settle this point of utmost interest for the theory we tried to find an element which is a proper analogue of zirconium and has the number 72. By investigating zirconium minerals with the aid of Moseley's method we ascertained the presence of a new element in appreciable amount, ranging from 2 to 20 per cent. in all minerals investigated, including specimens from Norway, Greenland, Italy, France, Russia, Ceylon, Brazil and North Carolina. Also in all commercial "pure" zirconium preparations the presence of at least 1 per cent. of the new element could be revealed. The determination of the exact wave length of eight characteristic X-ray lines gave the conclusive evidence that the new element has the atomic number 72. By using suitable methods to separate zirconium from thorium and titanium we succeeding in isolating the new element called hafnium (Hafnia=Copenhagen) from zirconium. Hafnium could easily be separated from the rare earth elements, and apart from this the determination of the optical spectrum of hafnium, which has been found entirely different from the optical spectrum found by Urbain for celtium, this affords conclusive evidence that hafnium is entirely different from celtium.

The chemical properties of hafnium lie closer to zirconium than to their other neighbour in the fourth vertical column of the periodic table, thorium. The high melting point, high power of light emission of the oxide, and the electron emission of the heated metal, exhibited by zirconium, are also shown by hafnium and the corresponding hafnium compounds. How far the latter have properties which, from the industrial point of view, are more advantageous than those of the corresponding zirconium compounds further investigations will reveal. Hafnium is abundant enough to be used for industrial purposes; it is found fairly concentrated in common zirconia and other zirconium minerals. For comparison the abundance of the elements of the silicon-thorium group in the earth's crust as estimated by Clark and Joly are given in the following table:—

Silicon	27·7	per cent. of the earth's crust
Titanium	0·46	,, ,, ,, ,, ,, ,,
Zirconium	0·017	,, ,, ,, ,, ,, ,,
Hafnium	>0·002	,, ,, ,, ,, ,, ,,
Thorium	0·002	,, ,, ,, ,, ,, ,,

THE PROGRESS OF THE BRITISH CHEMICAL INDUSTRY SINCE 1914

By H. LEVINSTEIN, M.Sc., Ph.D.

On July 17, 1919, I addressed a Conference on Dyestuffs, Synthetic Drugs and associated products at the Annual General Meeting of the Society of Chemical Industry.

On that occasion I stated the reasons which rendered the dyestuffs industry vital to the nation in peace as in war. None of the arguments used has been refuted since, but on the contrary they have been confirmed by subsequent events, for in 1921 the Dyestuffs (Import Regulation) Act was passed.

Similar considerations apply to the fine chemical industry, and this has been recognised by the passing into law of the Safeguarding of Industries Act. At the last General Election an attack on this Act was made by many who disliked it, only because they considered it to be the thin end of the wedge of Protection, and it is clear that at the present session it is again to be made an object of Parliamentary attack. Recently a referendum taken by the Manchester Chamber of Commerce showed a considerable body of opinion favourable to a repeal of these measures. It was shown, however, that few people question the necessity of maintaining the Dyestuffs Industry. The country in general holds the objects desired as essential to security.

During the last week or so two important statements have been issued by the Association of British Chemical Manufacturers—" The British Dyestuffs Industry " and " The Safeguarding of Industries Act and the Fine Chemical Industry." These publications give particulars of the growth of the industries. They deal very clearly and concisely with part of the ground which I am asked to cover. The pamphlets issued render my task easier and I am not going to give you a complete review of what has been done.

Heavy Chemicals

In the heavy chemical industry by far the most important development is the building of a synthetic-ammonia plant at Billingham by Messrs. Brunner, Mond & Co., Ltd. In the course of the war the Badische Co. built a very large Bosch-Haber plant at Merseburg, which is situated in the Stassfurt area. Salt, ammonia, carbon dioxide and lime are the important raw materials required for the ammonia-soda process. Ammonia is the most important of these. Carbon dioxide comes second. As carbon dioxide is a by-product obtained in the Haber ammonia synthesis you can see that a Haber ammonia plant erected on a brine field offers a great advantage in the manufacture of ammonia soda. The erection of a synthetic-nitrogen plant at Merseburg was therefore a threatening gesture to the British alkali industry. It is fortunate that Messrs. Brunner, Mond and Co., the most powerful British chemical company, have themselves undertaken to counter it.

The Billingham factory is to have a plant for the manufacture of 100 tons of 100 per cent. ammonia per day with provision for a rapid extension to 300 tons per day equal to 150,000 tons, rising to 450,000 tons of sulphate per annum. These figures compare with 250,000 tons of 100 per cent. ammonia, the annual production of Oppau. Merseburg has, I believe, double the production of Oppau.

The Billingham factory is well on the way to completion and the process is expected to be in full commercial operation during the current year. In conjunction with a contact nitric-acid plant the factory goes far to diminish our dependence on Chile saltpetre.

The importance of this in war time is clear. Germany must have collapsed after the Marne but for Oppau. We could not have carried on if the German blockade had cut off our Chile saltpetre. At Billingham is being created a new industry employing a large number of men to manufacture an indispensable product used in large quantities hitherto imported. It is the best kind of new industry. It enables us to become exporter of a bulk product of which we were formerly importers. We have 50 million people to feed and supply with raw materials. New industries which enable us to export additional quantities are essential.

The real significance of this development lies deeper. The country is impoverished by war. How can you seek more wisely to regain your lost wealth than by seeking to increase the fertility of our soil? What shorter road to wealth can chemists show than the way to compel the air and the earth to greater service in food production? In this sense the Haber process is one of the greatest achievements of practical science. Hitherto the winds directed the nitrogen uncontrolled over our surface. We wanted it, but knew no practical way to use it. Cyanamide and the Birkeland-Eyde process were impracticable for us. We had to use the nitrogen stored up Heaven knows how many years before in our coal or in saltpetre.

I look forward to what appears the natural corollary to this invention. Just as Chile nitrate beds or the guano deposits of the South Seas produce nitrogen fixed ages ago, so our coal fields and petroleum deposits give us cellulose degraded before our civilisation began.

Why should we wait for nature to carry out a change so clearly within the range of modern chemistry? The industries over whose development we are struggling all use coal tar as their raw material. What a way to make benzene from cellulose! It appears to me not inconceivable that we are on the verge of discovering a method of obtaining liquid fuels directly from cellulose. Sir John Russell has told us that by a simple fermentation 6–7 cubic feet of methane and hydrogen can be obtained from a ton of straw. I hope some day that we shall be able to make our liquid fuels by methods which will find employment for our synthetic industries and eliminate the lag of countless ages. There is at least to-day a glimpse of such a possibility.

Just as the Badische Anilin und Soda Fabrik impinged by its Merseburg factory on the alkali territory, so did an alkali firm, the Greisheim Elektron Co., the pioneers of electrolytic alkali and bleach, many years ago first impinge upon the dyestuffs industry to find an outlet for its liquid chlorine. The United Alkali Co. has followed a similar course and has developed an organic manufacturing branch which can feed the dyestuff and allied trades. Some twenty years ago this firm, already making benzol, commenced the manufacture of monochloro- and dinitrochlorobenzols.

During the war their dinitrophenol production was increased to 100 tons weekly. Pure ortho- and paranitrochlorobenzols were added and from the latter paranitrophenol was made. Benzyl chloride and benzoic acid have been made by the United Alkali Co. for three or four years, also acetic anhydride.

Other useful chemicals for colour makers, for instance, antimony pentachloride, anhydrous aluminium chloride, sulphuryl and thionyl chloride are also made.

The more recent additions to this company's range of intermediates include phosgene (carbonyl chloride) ortho- and parchloroaniline, dichloroaniline and its sulphonic acid, parachlorophenol and paranitro-orthoamidophenol. Many of these chemicals had to be made by my firm during the war and very troublesome some of them were.

When the manufacture of sulphur black commenced I think all the dyestuff makers obtained their dinitrochlorobenzene from Greisheim. Dinitrophenol itself was very quickly abandoned on account of its toxic character. Some of the larger German firms having chlorine plants subsequently made their own, but until the United Alkali Co. commenced the manufacture British industry at least continued to draw its supplies from Greisheim. Subsequently, Castner-Kellners made monochlorobenzene and this plant, too, was greatly developed during the war and proved of signal value to the dyestuffs industry.

One of the great advantages of the dyestuffs industry is that it acts as an outlet for chlorine and we may reasonably expect it will afford a still further outlet for the excellent chlorine products now made by Castner Kellner and the United Alkali Co. Phosgene was a particularly important substance during the war; it is now particularly important for the dyestuffs industry where the consumption is of course only a fraction of war-time requirements.

Apart from the above it appears to me that the most important developments in the heavy chemical industry have been the great increase in the manufacture of oleum and of liquid chlorine and the recent introduction of the elegant synthetical process for the production of hydrochloric acid.

Organic Chemicals

Acetyl cellulose.—With great deference to the Official Referee I propose to call this substance an organic chemical and not a heavy chemical.

The large works at Spondon manufacturing this substance are important and interesting for several reasons. In the first place they have a large carbide and synthetic acetic acid plant, now, unfortunately, not in operation. This new industry has attained large proportions in Canada. Clearly the manufacture of substances such as acetone, acetic acid and acetaldehyde from coal and lime marks a great technical advance important particularly to those countries where wood is scarce. It appears to me that the manufacture of carbide, acetylene and its derivatives are just the industries which we wanted, and which Providence intended us to have, when it permitted our forefathers to destroy our forests.

The synthetic manufacture of acetic acid has affected the price of methyl alcohol. A synthetic process for the manufacture of methyl alcohol would be invaluable to this country.

Secondly, acetyl cellulose is one of the war industries which appear likely to be important in peace. It links up the chemical industry with the cotton trade and should provide us in the future with a valuable industry.

Everybody knows the great increase that has taken place in viscose production necessitating considerable quantities of carbon bisulphide and caustic soda. The manufacture of viscose is a world industry and it is a British industry discovered, worked out and developed technically and commercially by British brains and British capital.

Photographic Chemicals

This industry prior to the war was in the hands of Germany, whose products had attained a great hold in all countries. During the war several firms took part in supplying the deficiency, especially Johnson & Sons and Claus and Co.

Four of the most important developers used in photography are :—

Metol (monomethylparamidophenol sulphate).
Amidol (diamidophenolhydrochloride).
Hydroquinone.
Paramidophenol hydrochloride.

Before the war none of these developers was manufactured in this country; the business was almost entirely in the hands of German agents, who were selling these developers under their German names.

In 1915 there was an urgent demand for metol from the War Office for the hospitals, because it gave the best results in X-ray work.

The manufacture of metol was not easy and it was some time before metol was produced in this country, and for a time what stocks there were had to be most carefully conserved for the use of the Government Departments.

In 1916 photographic aerial observation was realised to be of very great military importance and consequently there was an urgent need for metol and amidol for the development of the thousands of photographs which were taken by the airmen observers.

Fortunately by the time this aerial photographic observation had reached large proportions, metol was being made in this country, and though the Government demands were ever increasing, the British production was successfully increased to meet it.

British-made metol, amidol and other developers were supplied, not only to the War Office and other Government Departments, but to the Belgian Army, Italian Army, and when America came into the war large supplies were available for the American Air Force.

A good day's work for a photographic aerial observer produced 5000 negatives, from which 150,000 photographic prints would be made within 24 hours. On occasions photographs of positions 5 miles behind the enemy lines were taken by British airmen and finished photographs sent to Headquarters within half-an-hour.

The position at the present time is that British manufacturers are in a position to supply enough metol, amidol, paramidophenol, etc., to meet all the home requirements and to have a large surplus production for Colonial and export markets. The prices at which amidol and metol are now being sold in England are equal or below those at which the same developers were sold in the English market by the Germans before the war.

As a matter of fact, the German agents are doing their utmost to close down English production of these developers by selling them at prices which in some instances are 40 per cent. to 50 per cent. lower than their own pre-war prices. This they are able to do on account of the exchange and because the 33⅓ per cent. import duty is quite insufficient to adjust the German price.

The quality of the English developers has been pronounced on all sides by photographic users and by chemical analyses to be equal, if not superior, to the German productions.

Finer Chemicals for Research, Essences, Perfumery, Medicine and Industry

We have in this country many old-established firms who possessed international reputations before the war for some of their products—drugs, essences, perfumes, research and some industrial finer chemicals. To take but one instance, Howards were famous for quinine preparations before any one of us here was born. But the German firms controlled the markets and fixed the prices. No English firm made a range of research chemicals like Kahlbaum; bacteriological stains were Grubler's undisputed territory; photographic chemicals, like fur dyes, were the specialty of A.G.F.A. Synthetic perfumes were almost entirely foreign; there was no English Merck, no de Haen, no Schuchardt. Why not? Because in most cases the turnover of the English firms did not permit much research. The war created a demand. War restrictions made it difficult or impossible to meet the demands for products not directly required for war purposes. After the war, owing to prohibition, followed by the S.O.I. Act, many old-established firms enlarged their laboratories and with great boldness and skill put on the market a large range of these finer chemicals of unimpeachable quality.

In the statement on the fine chemical industry issued by the A.B.C.M. we are told that 2½ tons of this type of substance is now made for every ton made in 1913, and that double the number of hands are employed in their manufacture.

Mr. Carr tells me that the British Drug Houses alone have a list of over 3000 research chemicals.

A notable example of the effect of the S.O.I. Act is afforded by Messrs. Albright & Wilson. This firm has been a famous manufacturer of phosphorus and phosphorus derivatives certainly for longer than I can remember. The beautiful range of products manufactured by them and recently exhibited is a delight to any industrial chemist.

Their ammonium persulphate is far purer than the Continental product. The crystals are of 99·5 per cent. to 99·9 per cent. purity. They are stable in air and can even be packed in ordinary paper bags without losing strength. As everybody who has handled this product knows this was not so before the war as regards the German product. Surely this is important. Once specialists in phosphorus and its derivatives, they have been induced by the S.O.I. Act to take up the manufacture of other chemicals formerly only made abroad. Without this Act they would not have enlarged their research department, which has produced such admirable results and added to the prestige of British chemical industry.

Thorium Nitrate

The manufacture of thorium nitrate in this country, bringing along with it as a by-product mesothorium, is of importance because formerly monazite sand was controlled by Germany, and consequently the manufacture of thorium nitrate and of gas mantles became German territory. It is therefore important that Messrs. Hopkin & Williams possess a factory at Travancore where monazite sand is concentrated and that thorium nitrate is now a British product. These facts have become so well known owing to the recent litigation that I will not dwell upon them. It is well to bear in mind that titanium and zircon oxides can also be obtained from monazite sand and should if they have not already done so find application in the arts.

We had some contact quite early in the war with Messrs. W. J. Bush & Co., who now make so complete a range of products for perfumery, essences, drugs and other chemicals. I think they were the first makers of salicylic acid in this country; certainly it was possible to obtain salicylic acid, aceto-acetic-ester and other very useful products comparatively early in the war from this firm, all of which were of service to the dyestuffs industry.

Messrs. Burroughs Wellcome, whose pre-war research work stood out as a solitary but brilliant beacon on the coast, took over the salvarsan plant from Ellesmere Port when we acquired the indigo factory, and they quickly produced their now well-known kharsivan and neokharsivan of a purity not less than that of the Germans. These products are "difficile" to make and very toxic if impure. Their quick production was a fine and valuable work.

Messrs. Boots' work on saccharin was notable and to us particularly interesting, for the by-product paratoluol sulpho-chloride was of great use to us.

Chloramine T is another Boots' product which proved a notable success.

Aspirin was quickly made. The dyestuffs industry took some part in this and the quick improvisation of anæsthetics, novocaine and acriflavine, followed by proflavine and now euflavine.

Kerfoots also manufactured novocaine quite early in the war, the chief difficulty being the manufacture of ethylenechlorhydrin so largely used by the Badische both for the manufacture of indigo and mustard gas and not previously made here.

These early fruits just have their interest because they were so soon produced to meet urgent war necessities.

Of new industries which have arisen not covered in the above headings one should mention the manufacture of erinoid, a casein preparation, and the working of the German patents for the manufacture of synthetic tannins and for electro-osmosis. In the main, in my opinion, the chief developments of tanning by synthetic products remain to come; electro-osmosis has not fulfilled, as far as I can judge, the sanguine hopes that German literature might have encouraged. The separation of china clay into its finest particles by this method is not without importance, while the recent use of this fine china clay as a specific against cholera and dysentery is interesting.

Research Chemicals and Price

Twelve months ago a comparison with Kahlbaum's price list showed that on the average British products were only 29 per cent. dearer than the German pre-war prices for research chemicals, and we know that since that date British prices have been reduced. I have compared the prices of quite a number of research chemicals taken haphazardly from the British Drug Houses list and Kahlbaum's pre-war list, and on the whole Kahlbaum's seems to be dearer. Of course, to-day the Germans could use the exchange to undercut any British manufacturer for any chemical product, but that is hardly a circumstance that the Universities should trouble over. If they can get an assured supply of English chemicals of equal purity from British sources at Kahlbaum's pre-war price or thereabouts, they are in fact getting far better value than Kahlbaum ever gave them before the war, or would give to-day if the home supplies failed.

General Conclusions

You will observe that the developments in the fine chemical industry have mainly been carried out by old established firms who had world reputations prior to the war for some of their products. No real progress has been made by new comers without knowledge or experience. These old-established fine chemical firms had nucleus staffs and accumulated knowledge from which alone the developments could spring.

I should be very glad if those who are responsible for the formation of public opinion in connexion with the Acts we have already discussed would bear this in mind. You cannot create this kind of industry unless you have core, and this takes years to build; that we have always had. But the conditions were unfavourable as regards finance. Their turnover was restricted and the amounts that could be spent on research were consequently limited and the developments proportionately slow. Once the inhibiting factors were removed developments were extremely rapid, but in each case the firms had long experience. They had shown themselves capable of existence under trying conditions. These firms have increased their facilities for research, and within the next few years, with reasonable security, they should make important contributions to the nation's wealth.

The fact that we had these old and well-known firms placed us in a good jumping-off position. Now we have larger firms with more research laboratories, where new inventions may spring so that we may not always have to follow, but sometimes lead the world in the creation, abroad and at home, of demands for fresh products discovered by British chemists, made in British factories and marketed by British salesmen.

(*To be continued*)

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

Quite a Lot

of interest seems to be taken in the scientific exhibit in the Chemical Section at the Empire Exhibition next year. Although, especially in organic chemistry, the total output of research has been greater in Germany than in this country, if we consider the discoveries of really first-rate importance, this country has turned out at least its fair share. And now even in organic chemistry the amount of high-class research here is very gratifying. If the scientific exhibit is intended—as I believe it is—to show that British chemistry of the scientific variety is good enough for all the demands of the industry, then there is a very interesting story to tell. In particular in the modern work on radio-active bodies, the structure of the atom and similar subjects we make an uncommonly good showing, and Aston, the Braggs, Rutherford, Soddy and Thomson, to mention only six pioneers, make a team which is unique. I have put their names in alphabetical order to avoid displaying my ignorance of the relative degrees of their importance, besides which, when you have both a father and son to consider, the thing gets a little delicate.

Poetical Quotations

seem to appear in our *Journal* in all kinds of places, and I was calling the attention of an Oxford friend to these the other day and found some of them came from the works of our Poet Laureate, Dr. Bridges, who is himself—or at any rate once was—a chemist, and learned his chemistry from Odling and Matthieson. By the way, the death of Matthieson was not correctly given by Sir William Tilden in his pleasant recollections of his early youth. Matthieson died in 1870. I wish some of our senior chemical folk would give us some more recollections. A chatty account of Sir Charles Tennant, Dr. Mond, and other founders of the industry would be of interest to quite a number of us. What a change there is if we compare the chemical industry of to-day with what it was fifty years ago!

Advertisements

have always interested me, and I read them, or look at them, in several journals. I see there is to be a Professor of Chemical Engineering at University College, and wonder that more prominence is not given to such an announcement. I could furnish a number of instances which seem to show that our advertisers do not yet realise the varied interests of our many readers, who now include a goodly number of the pure and academic professors. Our readers not only read chemistry but all kinds of other books, some of the frivolous ones read novels, and even poetry. Professor Baly confesses to a love for Latin hexameters. If I were an editor I should organise a prize competition for the article which gave the best indication of the kinds of advertisements which will add most to the usefulness and interest of the *Journal*. I am not at all sure our advertisers have read our recent numbers with this aspect in their minds. If the firms who advertise in our *Journal* do not also read it, they not only fail to keep abreast of modern progress, but they miss the ingenious comments which I submit each week. They say that he who runs may read, but I often have to do my writing in this way. I wish someone would tell me what persulphate of ammonia is used for; I suppose I ought to know. I give my lawn a dressing of sulphate of ammonia every summer, but have not experimented with the *per* variety. At any rate, at Manchester the other week, Dr. Levinstein told us that we now make ammonium persulphate so much better than the Germans that it can be packed in paper bags. What the advantage of this is I don't quite know, but there it is.

The Editor Complains

that important communications reach him on Wednesdays just too late for insertion in that week's issue. I am an older hand at journalism than he is, and have got used to that sort of trouble. After all, a few days doesn't matter very much, and I have reached a period of life when I can view other people's troubles with considerable equanimity. All the same, it may be worth while to remind our readers that our *Journal* appears in two forms, and the printing of these cannot be done simultaneously, and the greater the number of *Journals* printed, the longer it takes to print and to dry and to bind and to post them. So if any writer is anxious to have his announcement appear at an early date, let him send it in at an early date. The day that any journal goes to press is a busy day for the editor, and he is generally in a bad temper. I do not know whether this is true of *Chemistry and Industry's* editor, for I always keep clear of him on Wednesdays. It is the only principle I rigidly adhere to. This is the busiest time of the year for a scientific journal; our own sections and those of other Societies are all hard at it and this is a sort of harvest time, which will be followed in the summer by a slackness due to holidays. Our editorial staff can then look forward to a time when the members cease from troubling, and the sections are at rest.

FORTHCOMING EVENTS

Mar. 17. Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 3 p.m. "Atomic Projectiles," by Sir E. Rutherford.

Mar. 19. The Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W. 1, at 7 p.m. "The Walschaert Locomotive Valve-Gear," by R. C. Bond.

Mar. 19. Institution of Rubber Industry, the Midland Hotel, Manchester. "Economic Side of the Industry from the Standpoint of the United States," by E. S. Babcox.

Mar. 19. The Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C. 2, at 7 p.m. Discussion on "The Need for Co-operation between Electrical Manufacturers and Contractors" (opened by H. T. Young and a Manufacturer).

Mar. 19. Royal Society of Arts, John Street, Adelphi, W.C. 2, at 8 p.m. (Cantor Lecture) "Accurate Length Measurement," by J. E. Sears, Junr. (Lecture 3).

Mar. 20. Royal Photographic Society of Great Britain, 35, Russell Square, W.C. 1, at 7 p.m. "The Preparation of Metol and its Homologues," by W. F. A. Ermen, M.A.

Mar. 21. Royal Society of Arts, at 8 p.m. "Some Curious Phenomena of Vision and their Practical Importance," by F. W. Edridge-Green, M.D.

Mar. 21. Society of Glass Technologists. Meeting in Birmingham.

Mar. 22. The Society of Dyers and Colourists, *Manchester Section*, 36, George Street, Manchester, at 7 p.m. "The Regularity of Yarns," by Dr. A. E. Oxley, M.A.

Mar. 23. Society of Chemical Industry, *Glasgow Section*, the N.B. Station Hotel, Glasgow, at 7.30 p.m. Annual Business Meeting.

Mar. 23. Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 9 p.m. "Life History of an Alpha Particle from Radium," by Sir E. Rutherford.

Mar. 24. Royal Institution of Great Britain, at 3 p.m. "Atomic Projectiles," by Sir E. Rutherford.

Apr. 4. Society of Public Analysts, Chemical Society's Rooms, Burlington House, W. 1, at 8 p.m. (1) "Physiological Standardisation," by Dr. Stanley White. (2) "An Investigation into the Chemistry of the Reinsch Test for Arsenic and Antimony, and its Extension to Bismuth," by B. S. Evans, B.Sc. (3) "The Estimation of Boric Acid in 'Liquid Eggs' and other Foodstuffs," by G. W. Monier-Williams, Ph.D.

Apr. 6. Society of Chemical Industry, *Manchester Section*, the Textile Institute, 16, St. Mary's Parsonage, Manchester, at 7 p.m. Annual General Meeting. "Activated-Sludge Process of Sewage Purification—Nitrogen Recovery," by Messrs. E. Ardern, P. Gaunt, and C. Jepson.

SOCIETY OF CHEMICAL INDUSTRY

ANNUAL GENERAL MEETING, 1923

The Annual General Meeting will be held on Thursday, June 21, at 11 a.m., and will be preceded by a meeting of the Council at 10 a.m. At the former, members will be welcomed to Cambridge by the Vice-Chancellor of the University, and the President of the Society, Dr. E. F. Armstrong, F.R.S., will deliver his address. In the evening there will be a reception and dance, also a lecture on Cambridge and its Colleges by Dr. Cranage.

On the Monday, Tuesday and Wednesday of the same week, the International Union of Pure and Applied Chemistry meets in Cambridge and the President of the Union extends a welcome to members of the Society to attend any of the public meetings of that body.

On Friday, June 22, the Society's Medal (1923) will be presented to Dr. C. C. Carpenter, who will then give an address. On the afternoon of the same day there will be an address by Dr. F. W. Aston, F.R.S., on "Isotopes," and in the evening the Annual Dinner of the Society, which ladies may attend, will be held. It is hoped that a large number of Cambridge guests will be present.

On Saturday there will be a visit to Ely.

At this Annual Meeting there will be no official Luncheon, but members and ladies may lunch in various College Halls. Arrangements will be made for parties to visit the various Colleges and Laboratories and a *rendez-vous* will be arranged, probably in one of the College gardens, where members may meet each other and where tea will be served in the afternoons. It is thought better to allow members to make up parties and plan their own excursions rather than that a pre-arranged programme should be provided for them. Information regarding hotels, etc., will be supplied later.

All communications should be addressed to the General Secretary at the offices of the Society in London until further notice.

NEWS FROM THE SECTIONS

BRISTOL SECTION

The annual meeting was held on March 1, Mr. M. W. Jones presiding, and Dr. H. Rixon read a paper on "Research."

The history of science reveals the fact that, unless research be undertaken with pure motives, it never attains a high level; work undertaken with a view to material advantage of any description is liable to stultify itself and represents, in the final balance, a very considerable energy loss. The investigator must be an altruist and he must publish his work, but publication should not be confused with advertisement. A much wider scope for publication is desirable. The censoring of publications, due in a measure to limited space, is not always an advantage, and a journal for the publication of negative experimental work would possibly save an enormous amount of time and be very valuable.

Research must be considered from the points of view of (*a*) the worker and his effect on research, and (*b*) research in its effect on the worker.

The second point is an educational question, as many students are unfitted to undertake research, and will never add anything new to the total of knowledge; but though they may contribute nothing to research, research may contribute very largely to their training in a manner that no other type of work can. The man who is to make any adequate addition to knowledge must possess insatiable curiosity, persistent energy, willingness to undertake and carry out the most arduous, dangerous, laborious or tedious work, and whilst capable of abstract and logical thought he must also be capable of imaginative flights. Physically he should be "tough," he should have no anxieties arising from income or domestic problems, and not too large a salary, but this should not depend upon the amount of work he turns out. Such a man will ultimately, in the course of his work, have to decide whether he prefers to work alone or with collaborators. The former method—typically English—results in small bulk of work with high quality; the latter—typically German—in greater quantity with a lower general quality. Different problems call for different methods, so that no comparison of the two methods is needed. Research must not be undertaken for gain, as a life devoted to the discovery of truth results in a certain limited fame and a modest competence; but the chief satisfaction should be in knowing that work has been well and truly done and the sum total of human knowledge increased.

SOUTH WALES SECTION

The first Annual Meeting of this Section was held in Cardiff on March 2, Prof. C. M. Thompson being in the chair. After the usual formal business the following officers for 1923-24 were elected:—Chairman, Capt. Hugh Vivian; Vice-Chairman, W. R. Bird; Hon. Treasurer, H. W. Webb, M.Sc., F.I.C.; Hon. Secretary, H. E. Cox, M.Sc., Ph.D., F.I.C.; Hon. Assistant Secretary, J. R. Green, M.C., B.Sc. Committee: H. J. Bailey, O.B.E., F.I.C., F. J. Bloomer, F.I.C., J. E. Coates, O.B.E., D.Sc., W. J. Cooper, F.I.C., G. W. Clegg, J. H. Duncan, W. J. Jones, D.Sc., F.I.C., Geo. Madel, C. A. Seyler, B.Sc., F.I.C., C. M. Thompson, D.Sc., M.A., E. A. Tyler, M.A., F.I.C., and J. H. Wells.

On the motion of Mr. A. Grounds it was decided to levy the sum of 5s. from all members of the Section (not associates) to form a Special Purposes Fund to be used for hospitality and sundry private expenses. The Chairman then presented the Hon. Secretary (Dr. H. E. Cox) with a clock with the best wishes of the members of the Section on the occasion of his recent marriage to mark their appreciation of the work he had done in connexion with the formation of the Section. He then reviewed the work and progress of the Section during the session; papers have been read at eight meetings, five in Cardiff and three in Swansea, and two visits have been paid to works. The membership now stands at 95 plus 9 associates.

Prof. Thompson then gave an address on "The Rare Earths in Relation to Incandescent Lighting." The subject dates from Berzelius, who, in studying the rare earths, noticed that thoria and zirconia gave out a bright light when heated; other landmarks in the history of the subject were the introduction of limelight in 1826 by Drummond and the illumination of parts of the city of Paris in 1876 by cones of zirconia and magnesia. The earliest forms of mantles were introduced about the year 1880, and consisted of platinum cones impregnated with rare oxides. Then began the classic researches of Auer von Welsbach, which led to the development in 1883-1891 of the familiar incandescent gas-mantles.

The lecturer outlined the chemical discoveries and researches of Welsbach, dwelling at some length upon the curious fact that a concentration of 1 per cent. ceria in 99 per cent. thoria exhibits a maximum luminosity. The belated success of the mantle industry led to the further investigation of monazite, the principal source of the rare earths, and to the development of magnetic methods for its separation from worthless sands. The peculiar solubility relations of the sulphates and phosphates of these elements were explained and illustrated by experiments. In conclusion, reference was made to the unsolved problem of why these compounds, when heated, emit such a good light; the speaker thought it probably due to the abnormal distribution of energy in their spectra, a greater amount appearing as light than as heat.

Mr. W. R. Bird then proposed a vote of thanks to Prof. Thompson for his interesting discourse and for his services in the chair during the session.

EDINBURGH AND EAST OF SCOTLAND SECTION

The Annual Meeting was held in the Hall of the Pharmaceutical Society, Edinburgh, on March 6, Dr. H. E. Watt in the Chair.

The following officers were appointed for the year 1923-24:—Chairman, Dr. Alexander Lauder; Vice-Chairman, Dr. H. E. Watt; Hon. Sec. and Treasurer, Mr. W. T. H. Williamson, B.Sc. The four vacancies on the Committee were filled by the election of the following members:—Messrs. W. A. Williams, G. F. Merson, D. S. Dawson, and J. G. Annan. Dr. T. Rettie was re-appointed Auditor. The Secretary's report on the work of the session showed that the membership stood at 149 in addition to 14 Associates.

The Annual Meeting was followed by an ordinary meeting, Dr. H. E. Watt presiding, and Mr. J. Rutherford Hill, Ph.C., read a paper on "Some Interesting and Historical Museum Specimens."

Specimens shown included several alkaloids isolated by historic chemical workers in Edinburgh, and a monkey-skin container filled with aloes brought from the Island of Socotra by Prof. Sir Isaac Bayley Balfour on his famous expedition in 1876. The aloes yielded only about 5 per cent. of crystalline aloin although therapeutically quite active. Some of the original crystalline aloin was exhibited that was made by T. and H. Smith, by whom it was discovered in 1850. Follicles and seeds were shown of *Strophanthus hispidus* sent by Buchanan from the Nyassa Lake district of Central Africa in 1883, to Prof. T. R. Fraser, and with which the latter made his classical researches on the pharmacology of strophanthus and the active glucoside strophanthin. A ball of Indian opium of date 1835 was shown, which was identical with the opium of which 1,000,000 balls were run into the harbour at Canton by the Chinese commandant, thus leading to the Chinese Opium War of 1840, in which the British and French compelled the opening of Chinese ports to British and French commerce. A sample of absorbent cotton was exhibited that was made in Edinburgh in 1879 by boiling in a 6 per cent. solution of potassium hydroxide, washing, placing in a bath of dilute hydrochloric acid, again washing and drying. This sample was made two years previous to the publication of the practically identical process of Slocum in 1881, which was usually regarded as the first known process. An original specimen was shown of the Ordeal Bean or Chopping Nut of Old Calabar (*Physostigma venenosum*), given by Rev. H. M. Waddell, first Scottish Missionary at Old Calabar, in 1846, to Dr. John Brown, author of "Rab and His Friends," and brother of Prof. A. Crum Brown. Sir Robert Christison narrowly escaped death by swallowing 12 grains of the bean; on becoming sick he swallowed his warm, soapy shaving water which acted as a prompt emetic. The seeds were successfully germinated in the garden of the famous surgeon, Dr. Syme, and also by Prof. J. Hutton Balfour in the Royal Botanic Garden. By the latter the plant was first described and named *Physostigma venenosum.* Specimens were shown of the original amorphous alkaloid, physostigmine or eserine prepared by Hesse and the crystallised alkaloid and its sulphate and hydrobromide recently prepared by T. and H. Smith. Prof. Sir T. R. Fraser was Christison's assistant and selected the Calabar bean as the subject of a pharmacological research for his M.D. thesis for which he was awarded the gold medal. He was Professor of Materia Medica while Crum Brown was Professor of Chemistry in the University. Crum Brown was a friend of Waddell and interested in the Calabar bean. In this way the chemist and the pharmacologist came to work together in a joint investigation of the relationship between chemical constitution and physiological action. Thus originated an epoch-making report on several aklaloids by Fraser and Crum Brown to the Royal Society of Edinburgh in 1863. This marked the pioneer work on a line of investigation which largely explains the wide modern developments in the production of synthetic drugs. Specimens were also shown of cinchonidine sulphate, quinidine, and an unnamed cinchona alkaloid presented in 1856 to Sir Robert Christison by John Elliot Howard, the great pioneer in production of cinchona alkaloids. The specimens are labelled in the handwriting of Howard, and it is stated that they were prepared by the "new and improved process" of Pasteur published in 1853. There was shown an interesting specimen of large prismatic double-refracting crystals of sodium salicylate containing six molecules of water. These had separated from an aqueous solution containing one ounce in three fluid ounces which was normally quite stable, but probably owing to exposure to a low temperature had crystallised. The crystals rapidly effloresced when exposed to the air. Remarkably large tubular crystals of salicin were exhibited, some as large as 25 × 8 × 2 mm., accidentally obtained by spontaneous evaporation in a basin that had been overlooked in the factory of T. and H. Smith. Samples were exhibited of oil of wintergreen (*Gaultheria procumbens*) and natural salicylic acid and sodium salicylate made therefrom, also of oil of sweet birch (*Betula lenta*). Both oils are nearly pure methyl esters of salicyclic acids, and attention was drawn to the fact that the glucoside in the leaf of wintergreen and the glucoside in the bark of sweet birch in contact with the enzyme in each in presence of water produced methyl salicylate at ordinary atmosphere temperature and pressure, whereas synthetic methyl salicylate was only obtainable in the laboratory by drastic treatment: in making sodium salicylate from sodium phenate and carbon dioxide by Kolbe's process, a heat gradually rising from 100° C. to 200° C. and continued for six or eight hours was required. It was the problem of bio-chemistry to discover the methods by which vegetable organisms accomplish these syntheses.

An interesting discussion followed the reading of the papers.

The Nichols Medal of the American Chemical Society has been awarded to Mr. Thomas Midgley, junr., of the General Motors Corporation, for his work on "anti-knock" compounds for internal-combustion engines.

MANCHESTER SECTION

The meeting of the Section, held on March 2, was preceded by a joint luncheon of the Manchester and Liverpool Sections, which has already been described by "Eye-Witness" and by a visit to the Manchester Corporation Gas Works in Bradford Road, which was visited by a large number of members.

This Gas Works is one of four stations under the control of the Manchester Gas Committee. The plant consists essentially of two retort houses of horizontal retorts and two new houses of vertical retorts—one, the Glover-West system, by the West Gas Improvement Co., Ltd., of Manchester; the other, the Woodall-Duckham plant, built by the Woodall-Duckham Co. Steaming is practised, and the yield of liquor is approximately 30 gallons of 10 oz. liquor per ton of coal charged. The coal is broken to about 1–1½ in. cubes, before being passed to the storage hoppers by bucket conveyors. The storage bunkers for coal will hold about three months' supply.

The Station makes its own electricity during the day by dynamos driven by steam from a series of Stirling water-tube boilers, fitted with chain-grate automatic underfed stokers and firing coke breeze. The three systems mentioned above are working under identical conditions from the point of view of coal supply, coke handling and treatment of the by-products and coal gas. A comparison of the results obtained from each plant will, therefore, be possible, and will yield most valuable information as to the relative efficiencies of the separate systems. This information will be available to the Gas Committee when they commence the construction of a new "super" gas works at Partington.

In the evening Dr. Levinstein, the new Chairman of the Manchester Section, read a paper which will appear nearly in full in this issue and the next. Before the paper was read Mr. Guy Radcliffe gave an interesting retrospect of the activities of the Section during the last forty years. The First General Meeting of the Society was held in London on June 28th and 29th, 1881, Prof. H. E. Roscoe being the President. Papers were read by Messrs. E. K. Muspratt, C. Graham, J. Mactear, Siemens, and Ludwig Mond. The London Section and the Liverpool Section both came into existence in 1881. The First Annual Meeting of the Society was held in Manchester on the 5th, 6th and 7th July, 1882, and the Manchester Section was formed in January, 1883. The Newcastle Chemical Society became a Section in the early part of 1883. Mr. Radcliffe gave some useful particulars of the early officers of the Society, and some of the early papers read, and we wish that the space available enabled us to print his retrospect at length.

The earliest history of the formation of the Society has often been a subject of controversy and is full of interest to the members.

CHEMICAL ENGINEERING GROUP

A meeting was held on March 12, in the Smoking Room of the Chemical Industry Club, with Mr. J. A. Reavell in the chair, and Mr. B. Heastie, M.I.C.E., read a paper on "Heat Transmission in Coolers, Heaters and Condensers."

The object of the paper is, briefly, to review our present very incomplete knowledge of the laws governing heat transmission. Heat may flow in three ways; by conduction, convection and radiation. In tubular heaters and coolers in common use, heat flows mainly by conduction and convection. The law governing the flow of heat by conduction and convection may be compared with Ohm's law for the flow of electricity: the potential difference causing the current to flow against the resistances in an electric circuit may be likened to the differences of temperature in a heat circuit. Three resistances will be met in transferring heat from saturated steam to a liquid through a metal plate, viz., (1) the film of condensed steam on the face of the plate, (2) the metal plate, and (3) a stationary film of water on the face of the plate in contact with the water. The total temperature drop is due chiefly to the resistance of the two films, the drop across the metal plate often being negligible in practice. Heat can be transmitted through the relatively stationary film of liquid adhering to the plate (or other solid) by conduction only. Since most gases and liquids are very poor conductors of heat there is usually a very great resistance to heat-flow in the boundary surface of a liquid or gas and a solid, accompanied by a large drop in temperature at that point. Incrustations or deposits from the liquid or gas also increase the resistance to heat flow. The lecturer then went on to discuss formulæ for calculating the coefficient of heat transfer from vapour to a metal wall. It was stated that the calculation of wall resistance was usually neglected in practice unless the film resistances were very small, as in high-velocity heaters. Further formulæ for deducing the liquor-film coefficient were discussed, and in connexion with the flow of gases through tubes, illustrations were adduced to show the fallacy of using superheated steam for heating or evaporation. Discussing heat transfer between liquids, it was shown that the transmission coefficient is higher when working at a higher range of temperature, but with the same temperature difference, probably owing to the lower viscosity and higher conductivity with increase of temperature. With gases, however, the viscosity increases with increasing temperatures. After discussing the transfer of heat between air and metal, a subject on which few data are available, viscous and turbulent flow was considered, and it was indicated that the production of turbulent flow in economisers and other water heaters was advisable to reduce corrosion. In conclusion, various methods of heating were considered.

THE UNIVERSITY OF LIVERPOOL

NEW CHEMICAL LABORATORIES

On Saturday, March 3, the new Chemical Laboratories of the University of Liverpool were formally opened by Viscount Haldane of Cloan. The speeches at this function were delivered in St. George's Hall, before a large audience. Vice-Chancellor Adami presided, and on the platform were Lord Haldane, the Lord Mayor of Liverpool, the Bishop of Liverpool, the Mayors of Birkenhead and Bootle, Pro-Chancellor Rathbone, Sir Max Muspratt, and a good many of the University professors and members of the Council. Viscount Haldane, in declaring the new buildings open, delivered a really eloquent address.

He contrasted the older Universities, which were secluded in situation and in other respects from the great manufacturing centres, with the modern Universities, which originated as colleges in great industrial cities. He traced the history of the movement which led to the dissociation of the Victoria University and the creation of the University of Liverpool, followed very shortly by the creation of the Northern Universities, and explained how essential it was that these new Universities should continue in close co-operation with the municipal and industrial activities of our modern centres of population. In Liverpool, which adjoins a great area of chemical manufacture, it was inevitable that chemistry should be a prominent subject, and it was proper and fortunate that the chemical manufacturers had done so much to support an institution the discoveries of which were essential to their progress and prosperity. It seemed to him that out of the misfortunes of the war had come a new profusion of ideas, a new prescience of spiritual activity. This was in accordance with the conclusions of Renan, who pointed out in "L'Avenir de la Science" that the greatest advances in science and poetry, in art and spiritual development, came not when nations were prosperous, but when they were under great misfortunes.

Lord Haldane alluded to the evidence that mass and energy were but different forms of the same identity, and said we were face to face with a state of things in which chemical knowledge was going to be, as far as could be foreseen, the very foundation of industry. Great advances had been made in physics, chemistry and mathematics, and the principles of these would be applied to industry with tremendous and revolutionary results. In this development the new Universities had an important part to play. Liverpool had done much and was now doing more, and he was sure that the scope of its activities had not yet reached its limits.

On the conclusion of the address Mr. Thornely, of the firm of Messrs. Briggs and Thornely, the architects of the new buildings, presented to Lord Haldane a ceremonial key and the laboratories were visited by both hosts and guests. The buildings are light and airy, spacious and well supplied with the apparatus, power and devices which are necessary for modern analysis and research. Naturally they are as up-to-date as possible and include the most modern forms of equipment. Several of the speakers alluded to the important work that has already been carried out in the chemical department of Liverpool, and the new buildings will give Professors Baly and Heilbron and their colleagues those greater facilities for research of which they have been in need. The position of students who have no immediate certainty of posts in academic or industrial positions has not been forgotten, and Sir Max Muspratt announced that, in addition to the other gifts made by him and his firm, the United Alkali Company had offered to post-graduate students two scholarships for research work. It is to be hoped that other firms will follow this excellent example. Some help of this sort is particularly valuable at Liverpool, because its reputation has already attracted a considerable influx of students to the chemical department.

In the evening the University Association entertained a large gathering to dinner at the Midland Adelphi Hotel. Vice-Chancellor Adami took the chair, and in proposing the health of Viscount Haldane, mentioned the great services he had rendered to the University during the struggle to obtain the status of a University and to the nation in many other capacities. In his reply Lord Haldane gave a very pleasant set of recollections of his activities in the law, in politics, at the War Office and in the work of education, and explained the necessity which compelled him in these different spheres to limit his work to very few problems. At the War Office he concentrated on the organisation of the Expeditionary Force; in education he had only time for one problem—the future of our Universities and in particular the newer Universities, now in number and importance nearly adequate to the needs of the country. He called attention to the fact that the fees paid by the students did not nearly cover the cost of their education, and that about two-thirds of this was provided by taxes, rates and endowments. It was important that the Universities should realise that the Labour Party would urge that educational advantages so largely maintained by the State should be available for all classes of the community. The Universities should set up in industrial areas minor University centres, where that thorough teaching which was their tradition could be made accessible to all those who were capable of profiting by it. Prof. Baly, responding to the toast of the "New Chemical Laboratories," said it was vital to the prosperity and security of the Empire that we should progress in science and claimed, what is probably now universally admitted, that there were as good chemists in England as in any other country.

MEETINGS OF OTHER SOCIETIES

INSTITUTE OF CHEMISTRY

A meeting of the Bristol and S.W. Counties Section was held on February 16, Mr. E. Russell, B.Sc., presiding. Dr. David Hooper, late quinine expert to the Madras Government, gave an interesting lecture on "Cinchona and Quinine in India," or the "Romance of Peruvian Bark," illustrated by the history of the introduction of cinchona and the manufacture of quinine in British India. The characteristics of the red bark, crown bark, and hedgers yellow bark were enumerated, and the features given of the districts in the Nilgiri Hills and Sikkim where they are grown. Praise was bestowed on the pioneers who overcame the difficulties of cultivation and manufacture and brought the alkaloid quinine within the reach of the people of India. Reference was made to the methods of harvesting the bark and the numerous experiments made in manuring the trees in order to increase the amount of alkaloid in the bark. The process was described of manufacturing "febrifuge," a mixture of alkaloids, and also that of the manufacture of sulphate of quinine by the oil process, the product being just as good as that turned out by the British and Continental factories. Quinine was still acknowledged to be the most effective remedy for malarial fever, one of the greatest scourges of the East. The vital need of possessing within the Empire our own cinchona plantations was strikingly brought home to us during the war.

The Chairman opened a discussion on the paper, in which Messrs. Storey, Littler, Andrews, Wintle, Barke and Wallace took part.

At the meeting of the Leeds Area Section on March 7, Capt. J. A. Foster read a paper on "Chemical Jurisprudence," in which he observed that chemical jurisprudence or forensic chemistry signifies the application of chemistry and chemical knowledge to the elucidation of questions in a Court of Justice. Forensic chemistry therefore includes all those branches of chemistry which help to solve questions arising during judicial proceedings. The branches of legal procedure in which a knowledge of chemistry is required are many. These branches may be divided into: (I) The Police Court: (*a*) Criminal; (*b*) Food and Drugs Acts, 1875, 1912; (*c*) Fertilisers and Feeding Stuffs Acts, 1906; (*d*) Rag Flock Acts, 1911; (*e*) Rivers Pollution, and Actions under Fisheries Board (Sea and Rivers); (*f*) Building Regulations. (II) County Court Proceedings, where claims for damages of and under 100*l*. are brought. These cases may arise from different sources, amongst which may be mentioned claims for selling goods not up to guarantee such as foods, fertilisers, feeding stuffs, oils, oilcakes, and deaths of livestock from causes on which the analyst has to give his opinion. (III) High Court cases.

Thus, the administration of the Foods and Drugs Acts depends wholly or almost entirely on the results of analyses. The same remark applies with almost equal force to many criminal actions. In many civil cases chemistry plays an important part and in some of these cases the chemistry of manufacturing processes is examined exhaustively.

Nature of Evidence.—In all legal proceedings the first essential is that the facts shall be brought before the Court in the most authentic form possible. This is done by giving evidence in the proper way—*i.e.*, facts are proved by either actual eye-witness or personal knowledge, and not by hearsay. It is specially enacted by the Food and Drugs Acts, and the Fertilisers and Feeding Stuffs Act that a certificate of analysis given by "a Public Analyst" or "An Official Agricultural Analyst" may be produced in Court and used as evidence without the appearance of the person who signed it.

Burden of Proof.—It is the duty of prosecutor or plaintiff to prove his case. Thus, if food or drugs are adulterated the prosecutor must prove adulteration. At times the burden of proof shifts from one party to the other. It may be taken as a rule that the evidence must be complete and conclusive. A very general defence is that the evidence is incomplete and inconclusive.

Chemical Evidence.—Chemical evidence deals with chemical facts and deductions. Such evidence is usually governed by the same rules as apply to other evidence, but there is one important exception. The ordinary witness as to fact is not allowed to give his opinion. The expert witness, a class which includes the chemist, is permitted a somewhat wider latitude. The chemist may, therefore, state not merely his facts, but also the deductions he has drawn from them, and the opinions he has formed thereon.

Functions of Chemist and Lawyer.—Although chemist and lawyer are both concerned in the preparation and formulation of chemical evidence, they are not necessarily familiar with each other's methods and requirements. Therefore, the chemist should know sufficient of the rules of evidence to make his analyses or experiments as useful as possible to the lawyer. Chemico-legal knowledge does not consist only in the acquisition of facts, but in the power of arranging them and in applying the conclusions to which they lead to the purposes of the law. A man may be a most skilful analyst or a most experienced chemist: his mind may be well stored with professional information; yet if he is unable by the use of simple language to make his information known to others, his knowledge will be of no avail. The first duty, therefore, of a chemical expert is to cultivate a faculty of minute observation combined with a general knowledge of what the law requires as evidence. In preparing evidence all the facts known to the expert should be clearly set down. An expert should remember that copies of his report and depositions, either before a Magistrate or Coroner, are usually placed in the hands of Counsel as well as of the Judge, and that his evidence, as given at the trial, is compared word for word with that which has already been recorded. Any serious deviations from what is on record will, of course, tell unfavourably against the witness, supply materials for a severe cross-examination and form an excellent ground of defence for the opposing side.

SOCIETY OF PUBLIC ANALYSTS

Three papers were read at the meeting held in Burlington House on March 7, Mr. P. A. Ellis Richards in the chair, members of the Medical Legal Society being present by special invitation to hear a paper on "The Examination of Firearms and Projectiles," by Mr. A. Lucas, O.B.E., Director of the Egyptian Government Laboratory, Cairo. This paper, which was read by Mr. C. Ainsworth Mitchell, discussed the scientific methods used for the identification of firearms and projectiles in cases of wounds or deaths from shooting. A particular weapon may sometimes be recognised by the rifling marks imprinted on a bullet, and the nature of the fouling left in the barrel after the weapon has been fired may also afford valuable information, both as to the nature of the original powder and also, in some cases, the period that has elapsed since the last discharge. The composition, dimensions and markings on bullets, slugs, etc., were described, and directions were given for the reproduction of rifling marks on bullets, and for the chemical analysis of projectiles of all kinds.

"The Interpretation of the Results Obtained in the Analysis of Potable Waters" was the title of a paper presented by Mr. R. C. Frederick, who gave an account of an extended investigation into the chemical changes which occur in samples of water polluted with excreta. The findings were considered in conjunction with the results obtained by the author in analysing a very large number of samples from every kind of supply throughout the British Isles. The orthodox ideas in regard to the interpretation of the analytical results of such examinations were criticised and the author's own views detailed.

Mr. S. B. Phillips read a paper on "The Determination of the Purity of Vanillin." After reviewing the various methods proposed from time to time, the author described (1) a volumetric method, and (2) a gravimetric method for estimating vanillin :—(1) One g. of vanillin is dissolved in 20 c.c. of neutral alcohol and acid impurities are neutralised ; 1·2 g. of *p*-toluidine is added and 20 c.c. of semi-normal sodium-hydroxide solution measured in, followed by 100 c.c. of cold water. The solution at 15° C. is titrated with semi-normal sulphuric acid until the permanent precipitate of the condensation product of vanillin and *p*-toluidine is formed. The difference between the volumes of alkali and acid represents the volume of alkali required to combine with the vanillin. (2) One g. of vanillin is dissolved in 13·6 c.c. of semi-normal sodium hydroxide, and a solution added of 2·4 g. semicarbazide hydrochloride plus 3 g. anhydrous sodium acetate (or 5 grams of the crystalline salt) in 30 c.c. of water. The mixture is heated on a boiling water bath for ten minutes, allowed to stand in the cold for four hours ; the semicarbazone is filtered off, washed, dried and weighed, treated with ammonium-hydroxide solution, and the insoluble portion filtered off, washed, dried and weighed. This weight is deducted from the original weight of semicarbazone and the remainder calculated to vanillin.

OPTICAL SOCIETY

At the Annual General Meeting held at the Imperial College on February 8, Emeritus Prof. A. Barr, D.Sc., was elected President, Major E. O. Henrici was elected Hon. Treasurer, and Prof. A. Pollard and F. F. S. Bryson, M.B.E., M.A., were elected Hon. Secretaries for 1923-24.

After the Annual Meeting Sir Frank Dyson delivered his Presidential Address on "Large Telescopes," in which he detailed the contribution made by them towards the progressive advance of astronomy. By means of the large reflectors of Lord Rosse and Lassell the heat from the moon was measured and new satellites of Uranus and Neptune were discovered. In 1868 a refractor of 26 inches aperture was made by Cooke for H. S. Newall, of Newcastle. This was soon followed by large telescopes in America by Alvan Clark, by Grubb in England, and the brothers Henry in France. In 1892, a 36-inch refractor was made for the Lick Observatory by Alvan Clark and a 40-inch one for the Yerkes Observatory in 1897. These large telescopes led to the discovery of new satellites and double stars, and to a very satisfactory knowledge of the masses of stars as well as of their velocities.

Mr. F. W. Preston, B.Sc., read a paper on "The Properties of Pitch Used in Working Optical Glass." Pitch as a material for mounting lenses for polishing possesses many remarkable advantages. Its colour is valuable ; the dull black surface in contact with the lens prevents reflection of light at the second face of the glass, and nothing better could be devised for the purpose of examining figure in a block. More than most similar materials in the "solid" state its co-efficient of expansion approximates to that of glass, it melts at a relatively low temperature, and remains plastic through a considerable range. A material with a definite melting point would be much more difficult to handle, and in the solid phase would need a co-efficient of expansion almost identical with that of the glass to be worked, or figure would always be bad. Even if this condition were satisfied, the material would be at a disadvantage as compared with pitch, since identity of expansion would preclude the use of refrigeration for parting. Pitch, being an undercooled liquid, may be made sufficiently solid to resist deformation by external pressures during the polishing operation, and yet left sufficiently plastic to yield to internal stresses, so as to be self-annealing at ordinary temperatures. The alteration of properties on prolonged heating is its most serious disadvantage, but methods of conservation and testing are available which obviate this, so that its unique properties can be utilised advantageously.

Instructor Commander T. Y. Baker showed a prismatic astrolabe designed and made at the Admiralty Research Laboratory, Teddington.

PHYSICAL SOCIETY

At the meeting held on March 9, Sir William Bragg read a paper on "The Crystalline Structure of Anthracene." X-ray measurements have now been made on crystals of anthracene more perfect in shape than those employed in previous work on this subject (*cf.* J., 1921, 429 R). The results obtained indicate that the lengths of the axes of the crystal unit of anthracene are $a=8{\cdot}58$ Å.U., $b=6{\cdot}02$ Å.U., and $c=11{\cdot}18$ Å.U. The data previously available gave $c=11{\cdot}6$ Å.U. The corresponding data for naphthalene are $a=8{\cdot}34$ Å.U., $b=5{\cdot}98$ Å.U. and $c=8{\cdot}68$ Å.U. The difference of length of the c axes of anthracene and naphthalene is therefore 2·50 Å.U., corresponding exactly with the width of the benzene ring as determined from the crystal structure of the diamond. The crystal molecule of anthracene possesses a centre of symmetry, and the molecular structure is such that if one set of identical molecules be placed at the corners of the unit cell, the centres of the other molecules lie at the centres of the *ab* faces. The specific gravity of a perfect crystal of anthracene, deduced from X-ray data, is 1·255, a value differing considerably from the commonly accepted value of 1·15.

In a paper on "A Radio-Acoustic Method of Locating Positions at Sea," Dr. A. B. Wood and Capt. H. E. Browne showed how the position of a ship at sea could be determined from the difference of the times taken by a radio-signal and an explosive wave produced by detonating a 9-oz. charge of guncotton under water to reach two or more stations of known position, equipped with radio-signal receivers and hydrophones of the microphone type.

A paper was submitted by Mr. J. H. Powell and Dr. J. H. T. Roberts on "The Frequency of Vibration of Circular Diaphragms."

INSTITUTION OF RUBBER INDUSTRY

A paper entitled "A Review of Solvent Recovery Processes" was read by Mr. T. W. Wild at the meeting of the Manchester Section on February 19.

As most of the solvents used in manufacturing processes are comparatively expensive, the prevention of waste is an insistent problem, particularly in the rubber industry, in which many thousands of gallons of solvents are lost annually. After describing the experiments which led to the use of cresol as an absorbent for ether and alcohol employed in manufacturing cordite, the lecturer outlined various processes used to recover solvents in the rubber industry.

All previous methods for the recovery of solvents used in rubber manufacture have relied upon the direct condensation of the vapours, but a large firm is utilising the absorption and redistillation system for recovering solvent naphtha. In a recent American process flue gas flows in contact with the fabric, and takes up the vaporised solvent, the resultant mixture of the flue gas and solvent vapour being separated. This method has been chiefly applied to the preparation of material for tyre manufacture. The flue gas, generated by burning any suitable fuel in special burners to remove the free oxygen from the air, is first scrubbed, then sprayed with water to remove dirt and soot, and dried. The flue gas then enters the drying chamber, which is a large compartment in the top and bottom of which there is a series of rollers. The cloth, first dried by passing it over hot cylinders, is passed into the chamber through a very narrow opening. Just inside the chamber are two dip tanks containing rubber solution. The cloth travels in a zig-zag path from top to bottom of the chamber between heating pipes or coils to evaporate the solvent. The flue gas enters the chamber where the fabric leaves it, and therefore flows in a direction opposite to the moving fabric. The solvent-laden flue gas then passes through a series of separators, condensers and compressors whereby the solvent is separated from the flue gas and conveyed by a common main to a receiving tank. The flue gas may be used again in the chamber. A register is attached to the apparatus to record the percentage of oxygen mixed with the flue gas, as it is vitally necessary to keep the proportion within safe limits from the danger of fire and explosion; 10 or 12 per cent. of oxygen in the flue gas is not objectionable, but usually the content is much lower. Flue gas coming directly from the fire for the drying of solvents cannot be used, as it is too hot (over 1000° F.), and contains moisture and sulphur dioxide that would damage the fabric. The waste of heat involved in cooling and purifying these gases is justified because of the protection it affords against fire and explosion. It is claimed that this apparatus will recover all but a very small percentage of the solvent used in treating the fabric.

This fascinating problem of solvent recovery has challenged man's ingenuity for many years; at least, this was true as regards the recovery of solvent from over-spreading machines until quite recently. The fundamental requirements of an ideal apparatus are as follows:—(1) Sufficient solvent must be recovered to show a substantial and constant profit after all expenses against the apparatus have been deducted; (2) the output of the spreading machine must not be reduced; (3) the possibility of fire must be no greater than on an uncovered machine and there should be no danger of an explosion; (4) the quality of the manufactures must be maintained. These essential features of a reliable apparatus were used as standards of efficiency in designing the "Voliq" apparatus, manufactured by the Solvents Recovery Co., Ltd. In this apparatus the drying chests of the spreading machine are covered with a close-fitting hood, made accessible at any part by hinged doors. About the centre of this hood is an exhaust box containing a fire screen which can be easily withdrawn for cleaning. The exhaust box is connected by means of a pipe to an air circulator mounted on a condenser, the base of which is connected to a re-heater placed under the spreading machine. At the other end of the re-heater a connecting duct is provided to convey the recirculated air to each end of the hood. The recovered solvent is separated from the air and deposited in the base of the condenser, from whence it is removed through a pipe to a storage tank and is ready for use again. The apparatus has been tested under ordinary working conditions during four years and it was found that 6 to 12 gallons of naphtha were recovered per day by each apparatus when fully employed during a working week of 48 hours. The quantity of solvent recovered varies, of course, with the class of work passing over the spreading machine. Taking an average recovery of 9 gallons per day, the yield per year of 273 working days would be 2457 gallons of coal-tar naphtha, which at to-day's price equals £215, whereas charges, including costs of maintenance and running, condenser water, power, oil, and an allowance of 15 per cent. for depreciation, etc., amount to about £80.

The output and quality of the product was the same as that obtained from an uncovered spreading machine and the danger of fire is no greater, the material damage done to the fabric being spread being less, because any fire is immediately choked underneath the hood by the products of combustion formed and by an insufficiency of oxygen. As there are so many loose, light doors and openings at the ends, etc., there is no likelihood of an explosion. Other advantages are that the drying of the fabric is improved, the hood protects the piece from falling dust, etc.—an important advantage when white or delicate shades are being spread—and the atmospheric conditions in the workroom are better.

SOCIETY OF DYERS AND COLOURISTS

A paper on "The Valuation of Dyestuffs by Titration Methods" was read by Reginald B. Brown and H. Jordan, at the meeting of the London Section held in the Dyers' Hall on March 8.

The rapid valuation of a number of commercial dyestuffs is carried out by the authors by titration methods based on the mutual precipitation of acid and basic colouring matters. They review the methods based on this principle which have already been proposed, commencing with Rawson's paper (1888) on the estimation of Naphthol Yellow by means of Night Blue, and including the systematic examination by Baenziger and Vlies in 1899 and Seyewetz in 1901 of a series of precipitates produced by the interaction of acid and basic dyestuffs.

Owing to the extraordinary conditions of the dyestuff industry in the years 1915-17, when it was frequently necessary to come to a decision regarding the purchase of a parcel of colour within an hour or so, the authors attempted to devise a method which could be carried out more rapidly than the usual dyeing tests and would yet afford a sufficiently exact indication of the colour value. For several of the more widely used dyestuffs, which are offered in many brands of varying strength, they have worked out titration methods allowing of an estimation of differences of 2 to 2·5 per cent., a nearer valuation than is possible by any dyeing or staining test.

The following principles are laid down:—(1) The dyestuff to be estimated and the volumetric reagent selected must be of quite different colour in solution, *e.g.*, blue with red, green or blue with yellow. (2) The acid colour should be run into the solution of the basic dyestuff; the reverse method is seldom useful. (3) In determining the end point a quick judgment must be formed. The strength of the dyestuff solutions employed is 1 g. in 500 cc., and the end point is recognised by the appearance in a spot made on filter paper of a ring of the colour of the precipitant solution.

Useful methods of valuation have been established for Auramine, by direct titration with Indigo Carmine, Methyl Violet with Naphthol Yellow S; and Victoria Blue B with Tartrazine. With most other basic dyestuffs, titration with an acid colour alone does not give a definite end point. In several cases a useful modification consists in titration with a solution containing tannic acid and sodium acetate in addition to the acid colour. Brilliant Green and Malachite Green are titrated with a solution containing 1 g. Orange II, 2 g. tannic. acid, and 2·5 g. sodium acetate per litre. Magenta and Saffranine are estimated by a similar method with Indigo Carmine in place of Orange II, and Rhodamine with Metanil

Yellow and the tannin addition. For Methylene Blue, Tartrazine or Crystal Scarlet, in either case with Tannin, may be employed.

For acid colours the process is the same, the volume of solution of acid dyestuff required to precipitate a given weight of basic colour being an index of the colour strength. Up to the present, trustworthy valuations are only possible of Orange I, Orange II, Tartrazine, and Naphthol Yellow S, and for all these dyestuffs the re-acting basic colour is Victoria Blue or Night Blue. Eosine can be estimated by running a solution of the dyestuff into a Malachite Green solution.

With direct cotton colours much less progress has been made. The method suggested by Baenziger and Vlies for the estimation of Benzopurpurine 4 B with Methylene Blue does not give a satisfactory end point whichever dyestuff is employed as precipitant. A better result is obtained by adding to the Benzopurpurine solution an excess of Victoria Blue B and titrating back with Orange II. An alternative is to add excess of Auramine and titrate back with Indigo Carmine, a method which serves also for the valuation of Chrysophonine.

It is found that concordant results are only obtained by working within certain limits of concentration ; if it is desired to value products which are very much stronger or weaker than the standard taken for comparison it is well to prepare a solution approximating to the usual colour strength. Another question which naturally arises is the effect of slight differences in the shade and therefore in the constitution of the products tested on the results of titration; such effect will depend on the molecular weights of the colouring matters and can only be investigated with precision with purified dyestuffs. The authors' personal experience has proved the method to be of considerable value ; several of the methods described have been in regular use in their laboratory for four or five years and have never yet led them astray. They hope to undertake later on a more scientific investigation of the laws governing the facts observed.

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The monthly meeting of the Council was held on March 5, Sir Max Muspratt, Bart., presiding. Dr. Clayton, M.P., received a hearty welcome on taking his seat for the first time as a member of the Council. The United Indigo and Chemical Co., Ltd., and the United Water Softeners, Ltd., were elected as members of the Association.

In connexion with the chemical regulations under the Factory and Workshop Acts, it was reported that manufacturers of bleaching powder were not opposed to the form of register suggested by the Chief Inspector of Factories, and that the Home Office had been advised accordingly.

As the result of negotiations the promoters of the Oakham Gas and Electricity Bill had agreed at the request of the Association to abandon Sub-Clause (3) of Clause 13 and to modify Clause 6, which enabled the undertaking to have unrestricted powers in chemical manufacture.

A conference has been held with the Medical Research Council with the view to closer co-operation between the medical profession and the chemical manufacturers, and further conferences with this object in view are likely to be held.

The British Industries Fair was more successful than ever last year, but in view of the British Empire Exhibition it was decided that the Association would not organise a Chemical Section of the Fair next year. A report from the general manager showed that great progress is being made on both the commercial and scientific sides of the British Empire Exhibition, 1924.

Certain points arising out of the administration of the Dyestuffs Act were considered.

It was agreed to give a donation of £250 towards the Chemical Society's Library.

A report from the transport manager stated that concessions had been obtained from the original proposals of the railway companies regarding the forms of schedule to be used in compiling the new standard rates.

PERSONALIA

The Meldola Medal of the Institute of Chemistry has been awarded for the second time to Dr. C. K. Ingold.

Mr. A. C. Nelson has succeeded Mr. H. Rook as chief chemist to the Clifton Coke Ovens, Cumberland.

Mr. T. J. Keenan, who has long been associated with the Technical Association of the Pulp and Paper Industry, has resigned the editorship of *Paper.*

Prof. F. Zambonini has been appointed professor of chemistry in the University of Naples, and Prof. E. Mameli has been nominated to a similar chair in the University of Perugia.

* * *

From Italy the deaths are announced of Dr. A. Castoldi, a well-known toxicologist and editor of the *Bolletino Chimico Farmaceutico,* and of Dr. Luigi Marino, lecturer in Applied Chemistry in the Engineering School, Pisa.

The death is announced of Dr. E. A. Merck, at the age of sixty-eight. Dr. Merck was the oldest member of the family which owns the well-known chemical works of E. Merck, and owned the Angel Pharmacy, founded in 1868, in the laboratory of which the production for the first time of alkaloids on a large scale, undertaken a century ago, marked the beginnings of the present factory.

CORRESPONDENCE

THE TITLE "CHEMIST"

Sir,—The Annual Meeting of the Institute of Chemistry affords the younger chemists an opportunity of expressing opinions at a public meeting, but the time available does not always permit their indiscretions to be commented on or corrected. At the recent meeting the younger members were supported in their aspersions of the pharmacist as a "chemist," and perhaps a few words of comment may correct their attitude, which seems to amount to jealousy.

The Authorities of the Pharmaceutical Society and the Institute of Chemistry both appreciate their rights in the matter, and the younger members of the latter body ought to be prepared to wait for the changes which time alone will effect without calling into question the rights conferred on pharmacists at a time when they were the only competent trained exponents of the chemical arts.

At the time the Pharmaceutical Society opened its laboratories in Bloomsbury Square, about the middle of last century, I believe the revered Fellow of the Institute of Chemistry, Dr. Tilden, was one of the students there, and it needs but little searching through the lists of Fellows of the Institute to find that some of the most prominent ones were trained as pharmacists.

The names Attfield, Redwood, Dunstan, Wynne and Collie are some of those who were for years Professors of Chemistry at the Pharmaceutical Society's School of Chemistry, and the men they trained had no option regarding their legal cognomen, "Chemist and Druggist" or "Pharmaceutical Chemist."

Yet we have this ever recurring quibble about the word or title "Chemist." The pharmacist is as proud of that title as a D.Sc. is of his degree, but the "law of the land" gave the pharmacist his right to the name "chemist" before B.Sc. degrees were granted all over the country and before even the modern chemical laboratory came into existence.

Who bothers about the title Apothecary now? Who ever sends for a Barber Surgeon or calls in the Leech? And as these titles have gradually lapsed, so the title "Chemist" will find the position it deserves, and be attached to the right man at the right time. Meanwhile, the newer members of the Institute of Chemistry would be wise to remember the debt they owe to the Pharmaceutical Society as one of the institutions which fostered and helped the Institute of Chemistry in its early days, when the science of chemistry was a novelty in this country.—I am, Sir, etc.,

C. Edward Sage

London

COLLOID CHEMISTRY

Sir,—With the assistance of prominent specialists the world over, I am preparing a comprehensive book on Colloid Chemistry, Theoretical and Applied. The extensive and international character of the book is evidenced by the subjoined list of some of those who have already promised contributions:—

U.S.A.:—E. G. Acheson, W. D. Bancroft, Carl Barus, M. H. Fischer, W. D. Harkins, H. N. Holmes, G. A. Hulett, D. D. Jackson, F. G. Kunz, R. S. Lillie, D. T. MacDougal, S. E. Sheppard, A. Silverman, E. B. Spear, E. W. Washburn, A. W. Thomas, H. A. Gardner. *England*:—E. F. Armstrong, Henry Bassett, W. M. Bayliss, E. F. Burton, W. B. Hardy, F. G. Donnan, F. E. Lloyd, A. E. Dunstan. *Austria*:—C. Doelter, W. Pauli. *Yugoslavia*:—M. Samec. *Sweden*:—Sven Oden. *Holland*:—H. R. Kruyt. *Mexico*:—A. L. Herrera. *Germany*:—H. Bechhold, G. Bredig, A. Fodor, H. Handovsky, A. Lottermoser, Lüppo-Cramer, R. Höber, W. Ostwald, H. Plauson, E. Stiasny, G. Tammann, H. Schade.

Many unusual experimental facts and practical applications of colloid chemical principles are unpublished, and the object of this letter is to ask anyone in any field of science or experience, who may have information of interest to send me a brief statement for inclusion in the book.

Contributions may consist of a paragraph, a page, or several pages, and will (unless contrary request is made) be duly acknowledged. If possible they should be submitted in English and duplicate copies will be appreciated. Authors should state their full names and titles.

The editors of scientific, technical, and cultural publications in all countries are asked to disseminate this appeal.—I am, Sir, etc.,

Jerome Alexander

50, East 41st Street,
New York City.
February 10, 1923.

MARKET PRICES

Sir,—In your recent issue dated March 2, 1923, your publication of a letter from Mr. P. E. Aldred expressing his inability to obtain the quoted market price for Wood Creosote suggests another aspect of the matter.

From a buyer's point of view the position appears to be different as will be apparent from the appended figures:—

		Magnesium turnings for Grignard's Reagent per lb.	Nickel pellets per lb.	Aluminium Sheet (1/16") per lb.
Manufacturer		5/3	1/6	1/6 (7–14 lb. lots)
Retailer	A	12/–	4/6	3/– (1 mm. thick)
	B	15/–	—	5/–
	C	16/–	5/–	7/6

These figures speak for themselves; no printable comment would be adequate.—I am Sir, etc.,

R. C. Gale

Woolwich
March 2, 1923

INDUSTRIAL HYGIENE AND THE LONDON SECTION

Sir,—As an example of unconscious inconsistency, I think that the meeting of the London Section of the Society of Chemical Industry on March 5 would be hard to beat. A hot crowded room, no apparent means of ventilation and nearly everyone present engaged in adding to the atmosphere the combustion products of vegetable matter—tobacco. I may say that I was not the only one obliged to make an early departure in search of a cleaner and more oxygenated atmosphere. And yet that meeting was solemnly discussing carbon monoxide poisoning, poisoning due to defective ventilation, the ignorance and apathy of workmen, and so on. "O wad some power the giftie gie us . . . ." —I am, Sir, etc.,

"Gassed."

St. Margarets-on-Thames
March 7, 1923

BAYBERRY OIL

Sir,—Your correspondent who inquires for this oil would have received a more satisfactory reply if he had explained the purpose for which the oil was required. There are two essential oils which own the name "Bayberry":—

1. The first is obtained from the leaves of the North American bayberry shrub, *Myrica cerifera*, and, relatively, is of very little importance.

2. The second is the essential oil obtained from bay berries, the fruits of *Pimenta acris* (Wight). This is the tree whose leaves yield us the well-known bay oil for making bay rum. The oil is similar in character to ordinary bay oil, but is richer in eugenol than, and consequently different in flavour from, the commercial oils.

I have not seen any of the berry oil in this country, but in New York I have heard of oil which was supposed to have been distilled from the berries. Either the old-established essential oil distillers in New York or their London agents would be able to supply or procure the oil from the bay berries.—I am, Sir, etc.,

C. Edward Sage

London
March 10, 1923

Sir,—Referring to your correspondent's inquiry on p. 241 of your current issue, the *essential* oil of bay berries is not an article of commerce. The bayberry oil of commerce, which is sold by wholesale druggists under the name "Oleum Bacc. Lauri," is the oil expressed from the ripe fruits of the bay laurel, *Laurus nobilis*, a small evergreen tree extensively cultivated in Europe. The oil is produced chiefly in Northern Italy by pressing the fruits after steaming or boiling with water. The berries yield about 30 per cent. of fatty oil, which is semi-solid in consistence, somewhat granular in appearance and greenish in colour. It consists mainly of glyceryl laurate, and has a pleasant aromatic odour. It is used as an outward application for rheumatism.

The essential oil of *Laurus nobilis* is obtained from the leaves and contains cineol. It is seldom used in this country. This must be distinguished from the essential oil of West Indian bay leaves. obtained from the leaves of *Pimenta acris* (*Myrcia acris*), which is the "oil of bay" of commerce. This contains eugenol and is the oil employed for making "bay rum."

Another tree known as "bayberry" is the Wax Myrtle (*Myrica cerifera*), the leaves of which also yield an essential oil of no commercial importance. Bayberry bark, obtained from a species of *Myrica*, is employed in pharmacy.

Trusting this information will be of service.
—I am, Sir, etc.,
C. T. Bennett
(Lecturer on Essential Oils at the Borough Polytechnic Institute)

London, S.E. 1
March 9, 1923

[We have also received a letter from Mr. Donald McDonald, stating that the bay berry is a N. American shrub known botanically as *Myrica cerifera* and referring to Sauer's "Odographia," Vol. 2, for further details.—Editor.]

NEWS AND NOTES

FRANCE

The National Fuel Problem

The problem of developing a national fuel, especially one based on home-made alcohol, is much to the fore in France. Recently, Monsieur Pineau, director of the Petroleum Section of the Ministry of Commerce, published a report setting forth the arguments in favour of the "national fuel" consisting of a mixture of alcohol and petrol. According to this report, the French State has stocks of alcohol exceeding one million hectolitres, and alcohol is produced in France, whereas all the petrol has to be imported; if beet cultivation were developed with a view to producing fuel alcohol, agriculture generally would benefit. The subject is arousing great interest and criticisms have been published of the national formula prescribing the addition of 40 to 50 per cent. of alcohol to petrol. Some consider that as alcohol costs more than petrol and has a lower calorific value, three litres of alcohol will be consumed where two of petrol would suffice. This is true, but the stocks of alcohol held by the State are sold at a price below that of petrol, and it is admitted that the price of petrol is too high. It is also suggested that certain by-products of coal should be added to petrol, and investigations on these lines are being carried out. In fact the recent discovery that it is possible catalytically to hydrogenate coal and its distillation products to produce liquid compounds related to petroleum suggests that a solution of the question lies in this direction. The utilisation of ethyl alcohol produced from cellulose is proposed by those who consider that an increased cultivation of sugar-beet would harm agriculture and reduce the area available for wheat. A difficulty is the production of stable mixtures of alcohol and petrol, for even traces of water render the mixture unstable. This question has been resolved by the industrial manufacture of practically absolute alcohol (99·70) by the process of Loriette. A further solution would be to add a third compound which would act as a " binder " between alcohol and petrol, but practical difficulties prevent this from being done. In 1922, 141,000 hectolitres of alcohol containing 50 per cent. of benzol were used by the Parisien motor-buses and many public carriers have also used this " National Fuel."

SOUTH AFRICA

Developments in the Coal Industry

A correspondent writing in *The Times* states that a London syndicate has secured options over areas of coal-bearing land in the Carolina district of the Transvaal. The syndicate, it is stated, proposes to develop coalmines on a large scale, and to build an electric railway to Kosi Bay or another Zululand port, which it would also develop. The estimated cost of the scheme is £25,000,000, but the actual capital mentioned is £50,000,000, and the Government is to be asked to guarantee £10,000,000. The coal is said to be of the highest quality and a scheme has been formulated to deliver it at the coast for 4s. 2d. per ton ; it is intended to grind the coal finely and transport it in steel pipes with water. The district in question has long been known as a promising mineral area, containing both gold and coal, but hitherto has not been exploited.

UNITED STATES

The Arsenic Industry

A Report issued by the United States Geological Survey states that the use of arsenic in weed-killing compounds has greatly increased during the past year, especially as calcium arsenate required in controlling the cotton-boll weevil, 8000 tons being used for this purpose in 1922. In addition arsenic is used in controlling mosquitos in the malarial regions in the south. The general shortage of arsenic resulted partly through the large increase in demand but also owing to the reduced supplies obtainable from copper and lead works and from abroad. At present the consumption of arsenic amounts to 12,000 short tons per annum, whereas in 1921 the supply from both domestic production and imports totalled only 6455 tons. Arsenic plants in the United States have an annual capacity of 18,300 tons of white arsenic, but their output depends largely upon the plants of two companies that intend to reduce ores directly for their content of arsenic.

GENERAL

Notes on New Zealand Ironsand

The isolation of a new element from Dominion sources is a matter of great interest to chemists of the British Empire. Large supplies should be obtainable on account of the abundance of the material and its freedom from zirconium.

Ironsands in New Zealand chiefly occur along the west coasts of both islands, where denudation and wave action are greatest. The deposits in the South Island, where the west coast is closely approached by the Southern Alps or their continuations, have yielded, and still yield, payable quantities of gold by skilful concentration. Most of the sands, however, are not auriferous, but consist essentially of titaniferous iron oxide associated with varying amounts of ferro-magnesian minerals. The sands are disposed in thick lenticular beds on the beaches and often extend inland for a mile or more. Enormous amounts are present, as these beaches often run for many miles. Near Patea, in the North Island, for example, there are over 5,000,000 tons. The pure sand is perfectly black, and to walk over it barefoot after it has been exposed to the hot summer sun of those latitudes is almost as good a test of innocence (or natural-leather soles) as the red-hot ploughshares of the Middle Ages.

The sand has been formed largely by the disintegration of andesitic and basaltic rocks which form a large part of the country behind the coast. It is an intimate mixture of magnetite, with varying proportions of hæmatite, and ilmenite, but some samples contain none of the last-named constituent. Usually between 60 and 70 per cent. of iron is present. The recent analyses quoted show that titania is often lower than in the sample analysed by Dr. Scott :—

	From Patea	From New Plymouth beach
Ferrous oxide	27·60	40·68
Ferric oxide	51·32	36·05
Manganous oxide	0·48	0·35
Titanium dioxide	9·60	9·20
Alumina	1·04	4·00
Lime	1·25	1·80
Magnesia	2·60	2·77
Silica	5·30	3·90
Phosphoric anhydride	0·25	0·09
Sulphuric anhydride	0·04	0·01
Vanadium pentoxide	0·32	n.d.
Water lost at 100° C.	0·20	0·25
	100·00	99·10

Numerous experiments have been carried out in order to determine the best conditions under which this sand may be smelted for iron. It has been found that the titanium content is not greatly altered either by mechanical or by magnetic separation. The sand when made into briquettes with a local clay has been successfully smelted with the production of a grey pig iron containing in one instance 0·245 per cent. of titanium.

Safety in Mines Research Board

The Explosives in Mines Research Committee (*cf. Chem. & Ind.*, p. 182) has prepared a memorandum outlining the history of the introduction and development of the special class of explosives known as "Permitted Explosives," used in coalmines in this and other countries, and the methods adopted for examining and testing them for this purpose. An indication is also given of the programme of research which the Committee proposes to undertake. Copies of the memorandum may be obtained, price 3d., from H.M. Stationery Office.

Sugar Beet Crop in Czechoslovakia

The 1922-23 crop of sugar beets in Czechoslovakia is estimated by the Central Association of Czechoslovak Sugar Manufacturers at 4,200,341 metric tons, and the yield of raw sugar at 717,240 m. t. These figures represent increases over the crop of 1921-22 of 23·65 per cent. for beets and 42·4 per cent. for sugar. Exports during the last four seasons have been roughly as follows (in metric tons):—1918–19, 160,604; 1910-20, 340,516; 1920-21, 414,376; 1921-22, 376,328. Almost one-half of the export was directed to Austria and France. During the season 1921-22 Czechoslovakia exported approximately 38,000 tons of sugar less than during the preceding year because it produced less. The big decrease in sugar exported to France was due chiefly to the reconstruction by that country of its sugar factories in the devastated areas.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for March* 8)

TARIFF CUSTOMS EXCISE

Australia.—The "dumping" duty on Portland cement of United Kingdom origin has been removed.

British India.—It is proposed to reduce the export duty on hides and skins by 5 per cent., and to increase the duty on salt from Rs. 1¼ to Rs. 2½ per maund.

Germany.—The export of pitch, tar and tar oils is prohibited.

Irish Free State.—Regulations have been issued controlling trade with the Irish Free State.

Italy.—By recent modifications in the customs tariff, mineral-oil distillation residues not for use as fuel, concentrated ammoniacal liquor, superphosphates, and sodium nitrate are admitted free of duty.

Mauritius.—Increased customs duties are leviable on kinematograph films, glassware (not sheet glass or laboratory appliances), perfumery, fireworks, and indigo.

Mexico.—Modified import duties have been applied to starch, rubber tyres and inner tubes, sheet zinc, and paper.

Poland.—An export tax, amounting to 50 per cent. of the profit derived from the export, is payable on sugar.

Russia.—The issue of March 8 contains a list of articles the import of which is prohibited. Many chemicals, minerals and metallurgical products are affected.

South Africa.—A "dumping" duty equal to the difference between the home and export prices but not exceeding 15 per cent. *ad valorem* has been applied to imports of Portland cement.

Switzerland.—General licences have been granted for the import of paper-making materials, and certain iron products.

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia ..	Hardware, hollow-ware, galvanised sheets, tinned and lead-coated sheets, metal tubes, carbon steel ..	*
British India	Cresol, quinine hydrochloride	†
Canada ..	Steel strip and wire ..	10691/E.D./ E.C.2.
Egypt ..	Palm-oil soap (tender for)	**
France ..	Oilseeds, fibre	322
Italy ..	Lighting glassware, aluminium and tin ware	323
Netherlands	Pharmaceutical chemicals	325
New Zealand	Celluloid goods, paper, thermometers ..	314
,, ,,	Glassware, crockery, rubber goods ..	315, 316
,, ,,	Chemicals, soap, aniline dyes, sulphur, caustic soda, alkalis, tin foil, edible oils	317
South Africa	Pharmaceutical preparations	318
,, ,,	Creosote (tender for) ..	10710/E.D./ C.C.2
United States	Iron and steel	18677/F.W./ E.C./A.2
,, ,,	Calcium arsenate, white arsenic	5411/A./ T.C./C.C.2
Yugoslavia	Tinplate	335

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Metallurgical Coke

Viscount Wolmer informed Mr. C. Lloyd that in 1922 the estimated production of metallurgical coke was 9,400,000 tons from 10,500 ovens, and the consumption in blast furnaces was between 5,750,000 and 6,000,000 t., compared with a production of 12,798,996 t. from 21,006 ovens, and a consumption of 11,760,000 t. in 1913.—(March 5.)

New Bills Introduced

On March 5, Mr. Lunn presented a Bill to nationalise the mines and minerals of Great Britain, and to provide for the national winning, distribution, and sale of coal and other minerals.

A Bill to amend the Safeguarding of Industries Act, 1921, in respect of agricultural produce was introduced by Capt. W. Benn on March 5.

The Pharmacy Bill, to regularise the position of all persons trading as chemists, druggists or pharmacists or proprietors in the sale of drugs, the transcribing of doctors' prescriptions and sale of patent medicines, was presented by Capt. O'Grady on March 8.

Sugar Duty

Capt. King, replying to Mr. A. V. Alexander, said that the revenue collected in the United Kingdom from the duty on sugar, molasses, glucose and saccharin during the current financial year up to the end of January last, amounted to £35,600,000.—(March 5.)

The Dyeing Industry

Answering Lieut.-Col. Hilder, Sir P. Lloyd-Greame said that he had no power to supervise the regulations of the associations of dyers in this country, even though they enforce regulations imposing a handicap on textile manufacturers.—(March 6.)

Excise Duty on Alcohol

In a written answer to Major Waring, Mr. Baldwin stated that relief from taxation was granted to manufacturers in respect of the bulk of commercial alcohol used by them for other than purely medicinal purposes. The amount of relief and consequent loss of revenue for the year ended March 21, 1922, was estimated at £24,000,000.—(March 6.)

Unemployment of China-clay Workers and Tin Miners

Replying to various questions, Sir M. Barlow said that the numbers of china-clay workers and tin miners registered as unemployed in February were 140 and 1834, respectively.—(March 7.)

Shortage of Coke and Pig Iron

Answering Mr. Jowett, Sir W. Joynson-Hicks, said he was aware that the demand for metallurgical coke for export had increased, and that there was a shortage of pig iron in some districts. The home output of both coke and pig iron was, however, being increased and there were indications that the demand for coke for export would not be maintained. The situation was being carefully watched.—(March 7.)

Supplies of Rubber

Sir Ormsby-Gore, replying to Mr. A. T. Davies, said that representations had been received from manufacturers of rubber goods regarding the effect of the policy for restricting the exports of rubber adopted by the late Government. The policy was intended to secure a stabilised price for crude rubber at a level at which it would return a reasonable profit to the growers. The policy was approved by the Colonial Governments concerned.—(March 7.)

LEGAL INTELLIGENCE

CLAIM FOR LOST AMMONIUM SULPHATE

The British Sulphate of Ammonia Federation *v.* the Clan Line Steamers, Ltd.

On February 20, Mr. Justice Rowlatt, in the King's Bench Division, heard an action by the British Sulphate of Ammonia Federation, Ltd., against the Clan Line Steamers, Ltd., to recover £147, the value of 40 bags of ammonium sulphate delivered to the defendant company at Birkenhead in 1920, for shipment to Mauritius.

For the defendant company it was denied that the bags were delivered and that the plaintiffs had suffered any loss. The plaintiff company claimed that the defendant company lost 40 bags out of a total of 1,000 bags delivered. The arrival of a consignment of 400 bags was not disputed. The other 600 bags was sent by one colliery on the London and North Western Railway, and documents showed that the bags were delivered. The records of the defendant company, however, did not agree. The point at issue was what deliveries had actually been made. Evidence was called to prove that the whole of the 1000 bags had been delivered, although receipt was only given by the defendant company for 960 bags. Evidence was submitted by the defendant company to show that there were no records of receipt of the bags, and it was argued that delivery of the bags had not been established in such a way as to rebut the evidence that rested on the wharfingers' receipts.

Mr. Justice Rowlatt said that the question was really whether 410 bags were received as the plaintiff company said, or only 370 as the defendant company claimed. The method of business was for bags to be sent by the London and North Western Railway Co., and for the company to send carts to deliver the goods to the docks. He had concluded from the evidence that the delivery of the bags was established and that there had been some mistake in regard to the checkings. Judgment was given for the plaintiff company for the sum claimed and costs.

REVIEWS

A Method for the Identification of pure Organic Compounds by a Systematic Analytical Procedure based on Physical Properties and Chemical Reactions. *By* S. P. Mulliken, Ph.D. *Vol. IV. Pp. vii*+238. *New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.*, 1922. *Price* $6.

To attempt to do justice to a publication, of which the fourth and last volume only, and also probably the shortest, is accessible to the reviewer would, as a rule, be to court failure. In the present instance, however, the book is of such a character that a fairly clear impression of the whole may, no doubt, be gathered from an examination of a part.

Dr. Mulliken has classified all the compounds mentioned in the first three volumes of the last complete edition of Beilstein's *Handbuch* (the edition now in progress of publication) and in more recent periodical literature, which, in his opinion, are of evident interest. The classification is based fundamentally on the nature and number of the elements contained in the compound, and the sequence in which elements other than carbon, hydrogen and oxygen are taken is that used in Richter's *Lexikon der Kohlenstoff Verbindungen.*

Thus Vol. I contains classified descriptions of about 2300 of the more important compounds of carbon with hydrogen and with hydrogen and oxygen. Vol. II deals similarly with the compounds containing carbon, hydrogen, oxygen and nitrogen, exclusive of the dyestuffs. Vol. III, which contained descriptions of the pre-war brands of commercial dyestuffs, is no longer on sale.

The present volume (IV) opens with some admirable general directions on the procedure to be followed in the indentification of an unknown compound belonging to one of the "higher orders" with which this volume deals. The compounds of "Order 3," containing chlorine as an "additional element" are then given. These are numbered consecutively for indexing purposes and are classed into Division A, Solid Species, and Division B, Liquid Species; in Division A, the compounds are arranged in the order of their melting points and in Division B, according to their boiling points, with a subsidiary classification into two groups based on the specific gravity of the liquid. These tables are followed by similar ones of those compounds in which the "additional element" is (*a*) bromine and then (*b*) iodine, and the description of the halogen derivatives occupies about one half of the book; then follow similar lists of substances containing as an "additional element," sulphur, nitrogen and chlorine, nitrogen and bromine, and so on; altogether about 3900 compounds are thus classified in Vol. IV.

In addition to the name and formula (usually structural), the melting point, or the boiling point and specific gravity, the table gives very briefly the odour, taste, behaviour towards solvents, simple reactions, and any other properties recorded in the literature which might serve for the identification of the compound. One noteworthy series of omissions, which it is difficult to account for, is that of halogen compounds of the terpene and camphor series, such as pinene hydrochloride, isobornyl chloride, chloro- and bromo-camphor.

The object of the whole book, it appears, is to assist a chemist to identify as rapidly as possible any organic compound, pure or impure, which he may come across in the course of his practice. For such a purpose Dr. Mulliken's tables would be of the utmost use and, obviously as regards those of Vol. III at any rate, it is already proved that they are in great demand. It is, perhaps, unlikely that Vol. IV will appeal to so large a number of chemists, but in any case the author may be complimented on the general excellence of his work.

F. Stanley Kipping

Farben-und Lackkalender. Taschenbuch für die Farben- und Lack-Industrie. *By* H. Wolff and W. Schlich. *Pp.* 177. *Stuttgart: Wissenschaftliche Verlagsgesellschaft*, 1923.

This little volume, of pocket size, contains a number of important data of service to those interested in the paint and varnish industries, whether as chemists, manufacturers, or merchants. The sections dealing with varnish are a masterpiece of condensation; the oils, resins —including artificial resins—and other raw materials of varnish-making are fully described and the methods of examining these products are given in sufficient detail. The properties and constants of the various solvents employed are shown in useful tabular form. Other sections deal with driers, coloured varnishes, cellulose varnishes ("Zaponlacke"), and with the testing and analysis of the finished products.

The treatment of pigment colours, apart from their use in opaque varnishes, is restricted to a tabular survey of the more important mineral colours and bases and a brief description of the usual tests for fineness, covering power, fastness, etc. The lakes produced from coal-tar dyestuffs do not come within the scope of the volume and rather more might have been said with advantage of such useful bases as blanc fixe and alumina hydrate.

The book concludes with information concerning the prevention of accidents in varnish works, German employment laws and German trade customs. The purchaser also secures a diary and note-book in a side pocket of the volume.

Reginald B. Brown

Handbook of Chemical Engineering. *Edited by* D. M. Liddell, A.I.M.E. *Vol. I. Pp. xi+517. Vol. II. Pp.* 519–1008. *New York and London: McGraw-Hill Book Co., Inc.,* 1922. *Price* 40*s.*

The appearance of this book is particularly welcome owing to the growing interest in this country in chemical engineering. It is produced under the editorship of Mr. Donald M. Liddell, assisted by a staff of 30 specialists. The book is divided into 31 sections, viz. :—

I—Generation and transmission of power. II—Material handling: the transportation of solids. III—The transportation of liquids. IV—The transportation of gases. V—Crushing and grinding. VI—Grading (sizing and screening). VII—Mechanical separation. VIII—Concentration. IX—Leaching and dissolving. X—Evaporation and drying. XI—Crystallisation. XII—Thermometry and pyrometry. XIII—Refractories. XIV—High-temperature production. XV—Mixing and kneading. XVI—Sampling. XVII—Fermentation. XVIII—Distillation: fractional; destructive. XIX—Refrigeration. XX—Oxidation. XXI—Electrochemistry. XXII—Catalysis. XXIII—Colloidal chemistry. XXIV—Smelting: Zinc—lead—copper—iron; roasting. XXV—Lutes and cements. XXVI—Radioactive elements. XXVII—Rare metals. XXVIII—Rare gases. XXIX—Materials of construction. XXX—Plant design. XXXI—Methods of financing.

The book is written by Americans and the descriptions of plant and processes are mainly confined to American practice. There is the advantage, however, that the English reader is introduced to a greater variety of labour-saving and automatic devices than he has known hitherto. The editor has allowed his contributors a very free hand in the treatment of their subjects. This has led to lack of continuity or coherence in the presentation of the theme and sometimes to overlapping and even contradiction. It comes as a shock to hear it doubted in one section whether hydrogen has ever been liquefied, or if xenon and neon really exist, whereas in a later section this scepticism has vanished. On the other hand, the treatment of such widely different branches by specialists is probably more serviceable than an attempt by one man to deal with so extensive a subject.

In no spirit of carping criticism, it is suggested that many of the sections cannot be properly called chemical engineering, although the subject matter is of great importance and assistance to the chemical engineer in carrying out his work. To those whose technical training has been chiefly chemical, the editor has presented in convenient form a mass of information which will prove of the greatest value in studying and carrying out industrial chemical operations. There is a great desire to produce good chemical engineers, and this book will simplify the task of the professors, and help those who have to teach themselves.

The book is strongest on the engineering side. One would have liked to see prominence given to the importance of thermochemistry and the necessity for reckoning with its teachings when carrying out chemical processes. The editor, in his preface, has largely disarmed criticism of omission, but one may hope that in a future edition the thermochemical side of the subject will receive attention.

In the section on Transportation of Liquids, a very complete list is given of substances which may be handled by pumps, and the materials of which the pump parts should be constructed. Also, in the section on Evaporation, the materials which can be used in constructing plant for use with specified solutions are stated.

The importance of the section on Sampling should not be overlooked as it too often is in general practice. The author says, "The utmost care is ordinarily given to all the operations of a chemical laboratory. Large sums are spent on its proper equipment and high salaries are paid to the chemists employed without regard to the fact that the accuracy of the analytical work is primarily limited by the accuracy of the samples furnished to the laboratories. It appears to be the customary assumption that any $3 a day man can prepare samples for a $20,000 staff of chemists."

The Editor says: "With much misgiving this book is sent forth in the hope that Chemical Engineers in all lines may find something of profit in the general principles laid down. . . ." He may rest assured that, however much one would have desired information on other matters not touched on in the book, cordial thanks are due for presenting so much that should prove of great value to all who are desirous of bringing more scientific knowledge to bear on the development and carrying on of chemical industry.

Wm. Macnab

REPORT

Report on the Trade and Commerce of East Africa, revised to September, 1922. *By* C. Kemp, *Officer-in-Charge, Nairobi. Department of Overseas Trade. Pp.* 44. *H.M. Stationery Office,* 1923. *Price* 1*s.* 6*d.*

With a view to fostering an export trade, railway rates on export produce have been cut in E. Africa, and ocean freights are, in many cases, quoted at losing figures. Lack of transport has prevented development of most of the area declared to contain coal, but trade is increasing generally. Money will have to be spent on transport (the railway to the Uasin Gishu Plateau is under construction), medical service, and education before trade can develop properly. Great Britain, controlling the bulk of the trade in East Africa, will benefit most from such developments.

The rubber situation, both in Uganda and Tanganyika, cannot improve until the home market shows a definite advance. The cost of delivering East African rubber to the London market is from 1s. 2d. to 1s. 6d. per lb. There has been a comparatively large increase in the amount of carbonate of soda exported by the Magadi Co. from Kenya, about 90 per cent. of the export going to Japan. Mica from an outcrop in the Uluguru Mountains, in Tanganyika, has been exported by Greek prospectors. The exploitation of minerals in general is in the prospecting stage only, and, apart from coal and oil, it is doubtful whether the local minerals could be exploited on a large scale. The Victoria Nyanza Sugar Co. expects to place its sugar on the market shortly, and later to develop an export trade in sugar. The electric power and light interests of Mombasa and Nairobi have been amalgamated, and the new company claims to have sufficient water power to supply all needs for many years. In Zanzibar and Tanganyika, soap manufacture is already carried on. Developments in the production of power alcohol are anticipated.

In East African trade, the initial cost of goods is the important point; quality is a secondary consideration. The United Kingdom's share of the trade with Kenya and Uganda has decreased. At present exports to Germany are financed through London, and imports are generally financed direct. The table below gives the values of the total imports and of the imports from the United Kingdom in respect of various materials for the years ending, respectively, March 31, 1920 and 1921 :—

	Total imports		Imports from United Kingdom	
	Year ending Mar. 31, 1920	Year ending Mar. 31, 1921	Year ending Mar. 31, 1920	Year ending Mar. 31, 1921
	£	£	£	£
Candles	668	2,706	203	846
Cement	20,085	67,036	19,721	60,360
Chemicals, etc.	10,843	20,426	6,868	15,757
Coal	2,731	23,829	—	14,424

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.	£22 10s. per ton. Firm tone still maintained. Advance expected.
Acid Hydrochloric	4s. per carboy.
Acid Nitric, 80° Tw.	£24 10s. per ton. Not in much demand on the open market.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw., is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% arsenical	£6 10s. per ton.
Ammonia Alkali	£7 12s. 6d.-£8 per ton. Fair request for home consumers with a firmer tone for export.
Arsenic (White)	£70 per ton. Prices nominal and very few parcels available.
Bisulphite of Lime	£7 per ton, packages extra and returnable.
Bleaching Powder	£10 10s.-£11 10s. per ton. No change in position.
Calcium Chloride	£6 per ton. No change.
Copper Sulphate	£26 10s. per ton f.o.b.
Potash Caustic, 88/90%	£29-£30 per ton. No change.
Potass. Bichromate	6¼d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton. Price unaltered and manufacturers are offering more freely than of late, but business has not reached very large dimensions.
Soda Caustic, 76%	£20-£21 per ton. Not in very brisk demand at present.
Soda Crystals	£5 5s. carr. paid. Manufacturers have reduced their prices 5s. per ton.
Sod. Acetate	£24 per ton. In better demand with very small quantities available.
Sod. Bicarbonate	£10 10s. per ton.
Sod. Bisulphite Powder, 60/62%	£19-£20 10s. per ton f.o.b. or f.o.r. London.
Sod. Chlorate	Market dull with spot parcels offering at 2⅞d. per lb.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide, solid 60/62	£15 per ton. No change.
Sod. Sulphite Pea Cryst.	£17-£17 10s., 1-cwt. wooden kegs included.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£10 per ton d/d.
Grey	£20 per ton d/d.
Liquor	9d. per gall. 32° Tw.
Charcoal	£9 10s.-£10 per ton.
Iron Liquor	1s. 6d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.

Red Liquor	1s. 3d. ,, ,, 14/15° Tw.
Wood Creosote	2s. 6d. ,, ,, Unrefined. Somewhat lower prices, however, are reported in some quarters.
Wood Naphtha—	
Miscible	6s. 6d. per gall. 60% O.P.
Solvent	5s. ,, ,, 40% O.P.
Wood Tar	£5 per ton d/d.
Brown Sugar of Lead	£39 per ton d/d.

TAR PRODUCTS

Acid Carbolic—	
Crystals	1s. 8d. per lb. Very strong market.
Crude 60's	3s. 9d.-4s. per gall. Good demand, price steady.
Acid Cresylic—	
97/99	1s. 11d.-2s. 3d. per gall. Very fair inquiries.
Pale 95%	1s. 11d.-2s. 2d. per gall.
Dark	1s. 9d.-2s. per gall. Fair demand at steady prices.
Anthracene Paste, 40%	4d. per unit per cwt. Price nominal, market stagnant.
Anthracene Oil—	
Strained	9d.-11d. per gall. Fair demand for small lots.
Unstrained	8½d. per gall.
Benzole—	
Crude 65's	1s. 1d. per gall.
Standard Motor	1s. 6½d.-1s. 8d. per gall.
Pure	2s.-2s. 6d. per gall. Not many inquiries.
Toluole—90%	1s. 9d.-2s. per gall. Fair inquiry.
Pure	1s. 11d.-2s. 3d. per gall. Market better.
Xylol	2s. 9d.-3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	1s.-1s. 1d. Fair business.
Middle Oil	8d.-10d. per gall. Market active.
Heavy	
Standard Specification	
Naphtha—	
Crude	9d.-9¼d. per gall.
Solvent 90/160	1s. 6d.-1s. 9d. per gall. Market dull.
Solvent 90/190	1s. 6d.-1s. 7d. per gall. Fair business.
Naphthalene Crude—	
Drained Creosote Salts	£6-£9 per ton. Market steady, but supply short.
Whizzed or hot pressed	£9-£12 per ton. Fair inquiry for forward delivery.
Naphthalene Crystals	£17 per ton.
Naphthalene Flaked	£16 per ton.
Pitch, Medium Soft	£8 17s. 6d.-£9 5s. per ton. Plenty of business.
Pyridine—90/140	11s.-12s. Little demand.
Heavy	8s.-9s. Price still nominal. No inquiries.

INTERMEDIATES AND DYES

Acetic Anhydride	1s. 5d. 100% basis.
Acid H.	5s. per lb. 100% basis d/d.
Acid Naphthionic	2s. 7½d. lb.100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic	1s. 6d. per lb.100% basis d/d.
Aluminium Chloride—	
Anhyd.	1s. per lb. d/d.
Aniline Oil and Salts	9½d. per lb. naked at works.
Antimony Pentachloride	1s. 1d. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis.
Benzyl Chloride	1s. 4½d. per lb. 100% basis.
Dinitrobenzene	11d.-1s. lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrophenol	£140 per ton.
Dinitrotoluene—48/50	8d.-9d. naked at works.
66/68	1s. 2d.-1s. 3d. naked at works.
Diphenylamine	3s. 2d. per lb. d/d.
Dichloraniline	2s. 2d. per lb. 100% basis.
Dichloraniline S Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. per lb. d/d, packages extra.
Metanitraniline	5s. 6d. per lb. d/d.
Meta Phenylene Diamine	5s. 6d. per lb. d/d.
Meta Toluylene Diamine	5s. per lb. d/d.
Monochlorbenzol	£70 per ton.
a-Naphthol	2s. 9d. per lb.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine	1s. 6½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	7d.-8d. per lb.
Nitronaphthalene	1s. per lb. d/d.
Naphthionate Soda	2s. 8½d. lb. 100% basis d/d.
Orthonitrochlorbenzol	2s. per lb. 100% basis d/d.
p-Chlorphenol	4s. 6d. per lb.
Paradichlorbenzol	£55 per ton.
Paranitrophenol	1s. 9d. per lb. 100% basis.
Parachloraniline	3s. per lb. 100% basis.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
Para Phenylene Diamine	12s. 6d. lb. 100% basis d/d.
Para Toluidine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

In view of the uncertain position with regard to deliveries from Continental manufacturers, prices for all pharmaceutical chemicals are much firmer, and as supplies on the spot are none too large higher prices are expected in face of any material demand.

Acid Acetic, 80%	£46 10s. to £47. Market very firm.
Acid Acetyl Salicylic	3s. 1d. per lb. Advanced. A very firm market. The price of Phenol justifies higher figures.
Acid Benzoic	2s. 3d. per lb.
Acid Boric, B.P.	£61 per ton Crystals, £65 per ton Powder, packages in 2-cwt. bags.
Acid Citric	1s. 8½d. per lb. Market firm.
Acid Gallic	3s. per lb.
Acid Pyrogallic, cryst.	5s. 6d. per lb.
Acid Salicylic	2s. per lb. Very firm. Price advancing. Only small supplies of foreign product available. Some prices quoted as high as 2s. 3d.-2s. 6d. per lb.
Acid Tannic	3s. 3d. per lb. Little demand.
Acid Tartaric	1s. 2¾d. per lb., less 5%. Raw material still very firm. Price tendency upward. Demand expected to improve.
Amidol	9s. per lb.
Acetanilide	1s. 6d. per lb. Steady.
Amidopyrin	13s. per lb., with little demand.
Ammon. Benzoate	3s. per lb. for good makes.
Ammon. Carbonate, B.P.	£37 10s. per ton nett.
Barbitone	14s. per lb.
Benzonaphthol	5s. per lb. Unchanged.
Bismuth Salts	Steady demand at previous rates.

Bromides	In view of possible shortage on the Continent prices are much steadier and are likely to go higher. A few second-hand parcels still available on spot.
Chloral Hydrate	4s. 3d. per lb. Firm.
Formaldehyde, 40%	£90-£92 10s. per ton.
Guaiacol Carbonate	8s. per lb. Unchanged.
Hexamine	4s. 3d. per lb. Very firm and likely to go higher.
Homatropine Hydrobromide	30s. per oz.
Iron. Ammon. Citrate	B.P. 2s. 5d. lb. Green 3s. 1d. lb. Market quiet.
Magnesium Carbonate—	
Light Commercial	£38 per ton.
Magnesium Oxide—	
Light Commercial	£85 per ton.
Heavy Commercial	£28 per ton.
Menthol	32s. to 33s. per lb. Poor demand. Prices lower.
Methyl Salicylate	2s. 4d. per lb. in bulk. Very firm in common with other phenol derivatives.
Methyl Sulphonal	13s. per lb.
Mercurials	Very firm. Quicksilver has advanced to previous price of £10 10s.-£11.
Paraformaldehyde	3s. 6d. per lb.
Paraldehyde	1s. 6d. per lb. Steady.
Phenacetin	5s. 3d. per lb.
Phenazone	7s. per lb.
Phenolphthalein	5s. per lb.
Potass. Bitartrate, 99/100% (Cream of Tartar)	95s.-100s. per cwt. less 2½%. Higher prices expected.
Potass. Iodide	15s. 8d. per lb. for cwt. lots. Cases free, good market.
Potass. Permanganate	9d. per lb. Very firm and a further advance is likely in the near future.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. Steady market.
Salol	2s. 4d. per lb. In steady demand.
Silver Proteinate	10s. 6d. per lb.
Sod. Benzoate	2s. 3d. per lb.
Sod. Citrate	U.S.P. quality, 2s. 2d. per lb. B.P.C., 2s. for quantity.
Sod. Hyposulphite— Photographic	£15-£17 per ton, according to quantity.
Sod. Potass. Tartrate (Rochelle Salt)	82s.-85s. Upward tendency.
Sod. Salicylate	2s. 4d. for Powder, 2s. 6d. for Crystal are the present rates, and with any large inquiry these prices would probably be advanced.
Tartar Emetic	1s. 4d.-1s. 6d. per lb.
Thymol	19s. per ib. Much firmer.

ESSENTIAL OILS

Anise Oil, Red Ship Brand	2s. 1d.
Cananga Oil, Java	9s.
Cinnamon Oil, Leaf	4d. per oz.
Cassia Oil, 80/85%	8s. 3d.
Citronella Oil—	
Java, 85/90%	4s.
Ceylon	3s. 6d.
Clove Oil	8s.-8s. 6d.
Eucalyptus Oil, 70/75%	1s. 8d.
Lavender Oil, Mont Blanc, 38/40%	12s. 6d.
Lemon Oil, spot	3s. New crop for shipment 2s. 11d.
Orange Oil, Sweet, Spot	10s. New crop for shipment 10s. 6d.
Otto of Rose Oil—	
Anatolian	24s.
Bulgarian	26s.
Palma Rosa Oil	17s.
Peppermint Oil—	
English, Mitcham	80s.
Wayne County	13s.
Japanese	6s. 6d.

PERFUMERY CHEMICALS

Amyl Acetate	2s. 3d.	per lb.
Amyl Butyrate	8s.	,,
Amyl Salicylate	3s. 3d.	,,
Anethol (melting point 21/22° C.)	4s. 6d.	,,
Benzyl Acetate from chlorine-free Benzyl Alcohol	3s.	,,
Benzyl Alcohol free from chlorine	3s.	,,
Benzaldehyde free from chlorine	3s.	,,
Benzyl Benzoate, 19.5° C.	3s.	
Cinnamic Aldehyde, 98/100%, Natural	14s. 9d.	,,
Coumarin	12s. 6d.	,,
Citronellol	22s. 6d.	,,
Citral, 100%	9s. 6d.	,,
Ethyl Phthalate	4s. 3d.	,,
Eugenol	11s.	,,
Geraniol (from Palma Rosa)	30s.	,,
Geraniol	6s. 6d.-12s. 6d.	per lb.
Iso Eugenol	18s. 6d.	per lb.
Linalol ex Bois de Rose	21s.	,,
Linalyl Acetate	22s. 6d.	,,
Methyl Benzoate	8s. 6d.	,,
Musk Xylol	9s.	,,
Phenyl Ethyl Acetate	10s.	,,
Phenyl Ethyl Alcohol	17s. 6d.	,,
Rhodinol	45s.	,,

TRADE NOTES

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the above Act made during the month of February, 1923, has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee.

The total number of applications received during the month was 646, of which 514 were from merchants and dealers. To these should be added 56 applications outstanding on February 1, making a total of 702 for the month. These were dealt with as follows:—

Granted, 463 (of which 441 were dealt with within seven days from receipt).

Referred to British makers of similar products, 121 (of which 116 were dealt with within seven days from receipt).

Referred to Reparation supplies available, 88 (all of which were dealt with within 48 hours of receipt).

Outstanding on February 28, 30 (mostly applications received on February 28).

Of the total number, 702, of applications received, 553, or 79 per cent. were dealt with within three days of receipt.

The French Chemical Market during February

The general tendency of the chemical market is towards increased prices, due chiefly to the cost of coal and fluctuations of certain foreign currencies.

Fertilisers were in active demand during the month. Orders for superphosphates are numerous and deliveries, to some extent, slow, owing to small stocks. The price may be expected to rise. Mineral superphosphate (14%) is quoted at 18 fr. at Nantes, 19 fr. at Rouen, Bordeaux and Marseilles, and 19·50 fr. at Brest; 16% superphosphate is quoted at 22 fr. at Marseilles and bone superphosphate (0·5% nitrogen and 10% phosphoric acid) at 34·50 fr. at Paris and 33·50 fr. at Somme. High prices of bone fertilisers are keeping back the demand. Basic slag is in short supply and manufacturers are only filling previous orders, so that a rise in price is anticipated. Quotations for basic slag at Thionville are:—17%, 14·45 fr.; 19%, 16·15 fr.; 21%, 17·25 fr. The nitrate of soda market is dull owing to fluctuations in the pound sterling. Stocks are normal, but insufficient to meet any sudden demand. French ammonium-sulphate manufacturers have fixed prices for March at 125 fr. per 100 kg. for common grade and 130 fr. for extra dry at works. French production is small. German deliveries have ceased and, despite the unfavourable exchange, buyers will probably have to turn to the English market to obtain stocks. Nitrate of lime is in great demand, but in short supply. Granulated cyanamide is no longer available, and the powder sells at 3·75 fr. per unit of nitrogen for samples averaging 18 to 21% of nitrogen. Among potash fertilisers, sylvinite is in good demand, but deliveries are slow and there are many inquiries for sulphate of potash. The sales of organic fertilisers except compound manures such as phosphatose and nitragine, continue active.

General Chemicals.—The demand for copper sulphate has caused the price to rise to 179 fr. at Marseilles (crystals); supplies of ferrous sulphate do not meet the demand.

Prices of petroleum products have risen generally. The *National Fuel* is quoted at 95 fr. per hectolitre on rail.

Prices of wood-distillation products have also risen generally, except turpentine, which is now quoted at 750 fr. the hectolitre. Prices of resin have risen still more rapidly and there is difficulty in obtaining supplies. A further rise of 15 to 20% in the price of wood-distillation products is probable.

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, MARCH 23, 1923 No. 12

EDITORIAL

EVER since the dry photographic plate was introduced by R. L. Maddox in 1871, the history of the photographic industry—founded on the discovery by Thomas Wedgwood in 1802 of a method of producing "sun-pictures"—has been one of constant progress. Starting with extremely slow plates, inefficient lenses, and few chemical reagents, the photographer now has a choice of reliable materials suitable for all, even the most unreasonable, conditions, and but rarely has he reason to complain. The Photographic Fair, an account of which is to be found elsewhere in this issue, bears striking testimony to the amount of scientific research and control which has gone to build up so large an industry, utilising such delicate reactions and materials. After Dr. Herbert Levinstein's speech in Manchester, detailing the progress of the British fine-chemical industry, the wide range of photographic chemicals exhibited by Messrs. Johnson & Sons came not as a surprise but as a pleasure, and we can only hope that the public will give this branch of the chemical industry the support it so surely deserves. To those accustomed to handling the older types of dry plate, the quality combined with the enormous speed attributed to the ultra-rapid plates of Ilford, Ltd., and of the Imperial Dry Plate Company, would seem exaggerated. But experience goes to show that the claim of speeds of 700 to 650 respectively, measured by the Hurter and Driffield system, for these plates is amply justified. Performance such as this well illustrates the perfection of modern plate making, and holds out hope of still further, undreamed improvements. The importance of this latest step in plate-making can be appreciated when it is remembered that, thirty years ago, the fastest plate available had a speed of 200 H. & D., and even then required the most careful handling, a disadvantage from which these modern ultra-rapid plates are free. It is also gratifying to learn that British base paper is now being largely used in the manufacture of photographic papers, and this and other advances indicate the progress made by what can not unreasonably be claimed as a branch of the fine-chemical industry.

* * *

It is a fortunate circumstance that in the year in which we celebrate the work of Pasteur we should be favoured by visits from some of our distinguished French colleagues. A number of these are in London this week and a larger number we hope to welcome at Cambridge in June. The work of Pasteur, perhaps not the greatest French chemist, but certainly the greatest man among French chemists, was developed from the earlier work on crystals to which his compatriots so largely contributed. It was Romé de l'Isle and Haüy in the eighteenth century who made crystallography a science, Malus, Arago and Biot in the first fifteen years of the nineteenth century who made the fundamental discoveries of polarization and optical activity. Charles Kestner, the great-uncle of our very good friend the President of the Société de Chimie Industrielle, discovered para-tartaric acid and de la Provostaye studied the crystalline forms of the tartrates and paratartrates. We ought not to forget the valuable work in some of these subjects of Gay-Lussac, but it is already evident that the genius of Pasteur was applied to a science which was as French then as the benefits conferred upon mankind are now international. Pasteur's work took him out of the domain of pure science, but others continued the investigation of crystals, and the light they throw on the constitution of chemical compounds.

* * *

Pasteur had some clear conception, founded on rather unreliable reasoning, as to the existence of asymmetric carbon atoms in optically active organic acids, but it was Professor Le

Bel, another visitor whose presence honours us this week, who worked out, simultaneously with but independently of van't Hoff, a complete theory of molecular asymmetry. His theory, published now nearly fifty years ago, has been tested in a great number of instances and is universally accepted, not even the disciples of Kolbe dissenting. We are proud to welcome the representatives of a nation which has advanced human knowledge to such a remarkable extent and glad that some of our own men of science, whose names are obvious, are worthily following in the paths, but dimly imagined by those of an early date, now identified as optical activity and crystal structure, including in this its application to tautomerism in organic compounds, co-ordination and the benzene ring.

* * *

It was only last week that we published some news about Hafnium; now whether this has or has not some disputed atomic number will be definitely known in a few weeks, and Professor Urbain, another of our distinguished guests, has so many pieces of first-class work to his credit that he will neither be unduly exalted if celtium turns out to have the atomic number 72 nor unduly depressed by disappointment if this turns out otherwise. His contributions to our knowledge of the rare earths and to spectroscopy have been so immense that his glory will be little affected either way. Professor Le Chatelier has worked out the general principles of resistance to change. We confess that our knowledge of thermo-dynamics is inadequate for a popular exposition of Le Chatelier's law, but it seems to us from a recollection of the correspondence which reached us after one or two innovations we attempted in the Journal that some of our readers have the principles thoroughly implanted in them.

* * *

The Abbé Senderens has for more than a score of years worked at catalysis, and he and Sabatier laid the foundations for the present processes of hydrogenation of oils; their work on nickel as a catalyst is of the utmost importance and is well known to all who are familiar with the use of catalysts in industrial operations. We alluded recently in our columns to the clergymen who, as a hobby, read and write on various branches of science, and without wishing in any way to slight the importance of their contributions, we may say that in its industrial applications the work of the Abbé Senderens exceeds all those we remember. Messieurs Kestner, Deschiens and Gérard have an enduring sign of their tact, skill and industry in the prosperity of the Société de Chimie Industrielle, and we are grateful to them, and particularly to Monsieur Kestner, for the extraordinary zeal they have shown in promoting a good feeling between French and English chemists.

THE PRODUCTION OF LEAD IN BRITAIN

By PROF. H. LOUIS, M.A., D.Sc.

(Continued)

Although smelting by natural draught was thus in use as late as the seventeenth century, it by no means follows that other furnaces worked by blast had not been introduced, and we have indeed evidence that such was the case. The fuel was, of course, either wood or charcoal. It is interesting to note that in "A Just and True Remonstrance of His Majestie's Mines Royal to His Majestie," addressed to King Charles the First, in 1641, by a Mr. Bushell, who was interested in the lead mines of Cardiganshire, the author states that he had had experiments made in order to "try whether fuel of turfe would separate the oare, extract the silver and reduce litharge" as well as charcoal, and found that he could do so by the use of charred peat. It is difficult to conceive that this experiment could have been a success unless the furnace had been worked by blast. The earliest account of this form of lead smelting appears to be contained in two notes from Joseph Glanvil, published in the *Philosophical Transactions*, for 1667[18] and 1668,[19] respectively. These were written in answer to a series of inquiries concerning mines, published in the above *Transactions* (Vol. II., No. 19, p. 331), and are stated to refer specifically to the operations as conducted in the lead mines of the Mendip Hills. The following are the two passages which refer to the smelting operations :—

"They beat the Ore small, then wash it clean in a running stream; then sift it in Iron Rudders[20]; then make of Clay or Firestone a Hearth or Furnace which they set in the Ground, and upon it build their Fire which is lighted with Charcoal and continued with young Oaken Gads[21], blown with bellows by Mens treading on them; and after a fire is lighted and the fireplace hot, they throw their Lead Ore upon the Wood which melts down into the Furnace; and then with an Iron-Ladle they take it out, and upon sand cast it into what forme they please."

"There is much difference in the goodness of the Ore; 36 hundred of Ore may yield a tun of lead. . . . They beat the Ore with an Iron flat piece; cleanse it in water from the dirt; sift it through a Wire-sive. The Ore tends to the bottom and the Refuse lies at top. And these are the Preparations they make use of before 'tis fit for fusion. Then they have a hearth about 5 foot high, set upon timber to be turn'd as a Wind-mill to avoid the inconvenience of Smoak upon a shifting Wind. The Hearth contains half a bushel of Ore and Coal, with bellowes on the top. The charcoale is put upon the Hearth where the Ore is; laying dry Gads upon the top, which they call their White coales. There is a sink upon the side of the Hearth, into which the lead runs, that holds about an hundred and an half. Then it is cast into Sand, and runs into those Sowes (as they call them) which they sell. They have a barr to stir the Fire; a shovel to throw it up; and a Ladle heated red-hot to cast out the Metal."

[18] Vol. II., No. 26, p. 525.

[19] Vol. III., No. 39, p. 767.

[20] *i.e.*, riddles or sieves (H.L.).

[21] *i.e.*, sticks or branches (H.L.).

It is interesting to note that this writer also refers to the use of the "Slagg-Hearth," although he does not seem to be very clear as to its exact purpose. The description is evidently written at second-hand, but gives upon the whole a fairly good idea of the method of smelting in use at the time. Apparently there was no great change in the process for some considerable time, as may be gathered by the description of lead smelting in Derbyshire, by John Martyn, F.R.S., written in 1729[22]:—

"When the Ore is brought up from the Mine it is broken to Pieces so that the Spar, Cawk, or other Bodies which adher'd to it may be the more easily separated. It is then thrown into a large Sieve and washed, and so farther purified from extraneous Bodies. After this it is carried to the Furnace in order to be smelted. The Furnace which I saw near Warksworth was very rude and simple, consisting only of some large rough stones placed in such a manner as to form a square Cavity, into which the Ore and Coals are thrown *stratum super stratum*; two great Bellows continually blowing the fire being moved alternately by Water. I saw no other Fuel used on this Occasion but dried sticks which they call white Coal. Mr. Ray informs us that they use both white and black Coal or Charcoal in Cardiganshire. . . . When the Ore is melted it runs out at an opening in the bottom part of the Front of the Furnace, through a small Channel made for the Purpose, into a cylindrical Vessel out of which it is laded into the Mould. The Dross of the Ore on smelting is called Slag. This Slag is afterwards smelted again with Coke only and the lead obtained from it is called *Slag-lead*."

The most detailed and accurate information that we possess concerning the history of lead smelting is to be found in the accounts of the Bishopric of Durham, which have been kept carefully for many centuries and which owe their value to the fact that the See of Durham owned the lead mines of Weardale from a very early period. Roman remains have been found in Weardale, notably the Roman altar dating from about A.D. 240, which was discovered close to the village of Eastgate in 1869, but there is no evidence at all that the lead mines of this region were worked by the Romans. The first definite reference is the well-known Charter of Stephen, in which he grants absolutely the "minariam de Werdela" to his nephew Bishop Hugh Pudsey, whilst the latter in his turn granted a lead mine for roofing certain of the churches in Durham.[23] All through the twelfth and thirteenth centuries there are references to these mines. In 1426 there are detailed accounts of the smelting of the lead at "Les Bolehill" at Wolsingham. Payments were made to certain specified "bolers," whilst it is definitely stated that a certain amount of lead was smelted by the use of a wheel and by the feet of men, referring apparently to bellows worked by water-power and by foot.[24] It may be assumed that the wind furnace would be used whenever the wind was suitable, but that under other conditions mechanically produced blast would be employed. The type of hearth was probably very much the same as it was in Derbyshire in 1729, as described by Martyn. This furnace was obviously the prototype of the ore hearth, or Scotch hearth, as we know it to-day. Although this furnace is and has long been built of cast-iron blocks, these are still known as "stones"—*e.g.*, the pipe stone or cast-iron block through which the tuyere passes, the work-stone or sloping plate of cast iron which forms the front of the furnace, etc. These terms make it appear highly probable that the ore hearth is a direct descendant of the crude furnaces above referred to. For another century these methods of smelting continued, though it appears that slag hearths were already in use in the latter part of the fifteenth century, as there are several records in the Durham accounts of payments for carting "blackwerk" (in all probability black slag) from the "boilisted" to the "smelting place."[25] Probably about this time the shortage of fuel began to make itself felt, and this would have induced Cardinal Wolsey, who at that period held the Bishopric of Durham, to attempt to smelt lead with pit coal, which attempt was made at a "great furnace" at Gateshead. Though we have no record of the construction of this furnace, or of how it was intended to carry out the process, it is quite evident that the experiment was a failure. In 1527 Cardinal Wolsey leased his furnace at Gateshead and all mines within the Bishopric for a term of thirty years at a rent of £5 per annum, and for another century nothing further is heard of any attempt to use mineral fuel. In 1678 the patent right was granted to George Lord Viscount Grandison, "to melt and refine lead oare in close or reverberatory furnaces with pitt coale or sea coale," etc; and 1690, John Hodges obtained a patent for "a way of melting and refincing lead ore in close or reverberatory furnaces with pitt coal," etc."[26] It is highly probable that one or both of these patents formed the basis upon which was founded the important Company generally spoken of as the London Lead Company, the full title of which is the Governor and Company for Smelting down Lead with Pit Coal and Sea Coal, founded in London in the year 1692, under a Charter of William and Mary. From a modest beginning this Company extended its operations all over the kingdom, and for over two centuries it exercised a most important influence upon the progress of lead smelting in Great Britain. This Company appears to have been originally formed to apply this process of lead smelting to works at Bownham, near Bristol. It soon acquired lead mines in Wales, some of which were in full work during the Middle Ages. The first notice of the lead mines of Cardiganshire dates back to 1485, when Henry VII. appointed Jasper Duke of Bedford and certain others to be the Commissioners and Governors of all his Mines of gold, silver, tin, lead and copper in England and Wales. The Society of the Mines Royal was formed under patent granted by Queen Elizabeth in 1568, and several of the Cardiganshire lead mines worked under this corporation. It is recorded that in 1667 these mines had four great wheels which worked the bellows and the stampers.[27] In 1704 the London Lead Company acquired mines in Alston Moor, and about twenty years later various others in Durham. Again in 1745 the Company leased a number of mines in the Teesdale district, with which it remained closely connected up to the end of its career. It also extended its operations into Scotland. The mines of Wanlockhead and Leadhills appear to have been worked in the thirteenth century. Sir James Stampfield worked them from 1680 to 1691, and apparently in 1721 they were leased to the London Lead Company, but it appears that this tenure terminated in 1755.[28] In 1792 the Company concentrated its operations in the dales of Durham and the northern portion of Yorkshire, and their holdings must have been considerable, seeing that in 1809 they paid to the Bishop of Durham royalties of over £5000 in respect of the Weardale mines.

[24] Ibid., p. 349.

[25] Loc. cit., p. 351. The above spelling suggests that possibly a bole-hill or bole-stead was a place where lead was "boiled," *i.e.*, smelted out of the ore.

[26] Percy's Metallurgy of Lead, p. 218.

The Company appears to have prospered exceedingly up till about the middle of the nineteenth century, when its production began to fall off. Some of the mines in Teesdale and the smelting works at Eggleston continued in operation on a very reduced scale until this famous old company was finally wound up in 1905.[29]

The reverberatory furnace was apparently introduced in Flintshire about the beginning of the seventeenth century, and within the next fifty years these furnaces, or cupola furnaces as they were then called, had spread to the other lead smelting districts of England, and both the reverberatory furnace and the ore hearth have continued in use up to our time. The successive modifications in the smelting process are well shown in a chapter on the "Smelting of Lead Ore," by John Farey.[30] The following are some of the more important extracts from this writer :—

"In the early periods of the Mining in Derbyshire, the Ore was smelted on the tops or western brows of high Hills, by fires made of Wood, and blown by the Wind only, as is supposed, piles of stones being made round the fire, and perhaps arches were formed underneath them, to favour and increase the effect of the wind on the fire : these ancient hearths were called Boles, and whence many of the highest Hills in and near to the Lead Districts obtained their names.

"These very ancient Boles or Wind Hearths were succeeded by Slag-mills or Hearths almost like a Blacksmith's forge on a large scale, blown by large bellows worked by Men or by Water, one of which is still to be seen attached to each of the Cupolas that can command a stream of water, for re-melting the black or drawn Slag of their Cupolas.

"The Cupolas or low-arched Reverberatory Furnaces, now exclusively used for the smelting of Lead-Ore in Derbyshire, were introduced from Wales by a company of Quakers, about the year 1747, the first of which was erected at Kelstedge, in Ashover."

A full description is given of the method of smelting in a reverberatory furnace of the then most modern type, the furnace being 10 ft. long and 6 ft. wide in the middle inside, connected by flue with a stack 50 ft. in height with doors or openings on either side. The usual charge is stated to be 16 cwt. of 120 lb. each, and the charge is said to take from seven to eight hours to work, the produce being about 66 per cent. of metal. The author states, however, that "The quality of the Ore has become so much worse, owing to the low state of the Mines, that a charge of 16 cwt. of Ore, produces more Slag now than 20 cwt. did about twenty years ago, and is still increasing." Incidentally, it is interesting to note that the writer voices the complaint which we constantly hear in our time as to the number of different units of weight in use :—

"The Pieces or half Pigs of Lead are not of any certain weight, though the Smelter here endeavours, in filling the Mould, to approach as near to 176¼ Avoirdupois as he can, this being the 16th part of the Mill-fodder in use here, consisting of 23½ long cwt. (of 120 lb.) or 2820 lb., which is the largest of twelve Fodders used in different places, to the no small inconvenience and disgrace of this Trade."

[28] The Wanlock Head Lead Mines. By John Mitchell. The Mining Magazine, July, 1919, Vol. XXI., p. 11.

[29] Victoria History of England: Durham: Mining, p. 352.

[30] General View of the Agriculture and Minerals of Derbyshire, by John Farey, Senr., Mineral Surveyor, 1811, Vol. 1, p. 380, 383, 385, 390.

The process appears to have undergone but little modification since the beginning of last century. Thus, Dr. John Percy, in his Classical work on Lead, gives an account of lead smelting in the reverberatory furnace, or the Flintshire furnace as he calls it, from which it would appear that in 1859 the hearth was about 10 ft. long and 9 ft. wide; that it received a charge of 21 cwt. of ore, which was worked in six hours with a consumption of 12 to 16 cwt. of coal, yielding about 63 per cent. of lead direct from the furnace and producing about 4 cwt. of slag. Apparently the view of most smelters appears to be that this type of reverberatory furnace had better be replaced than improved, more recent practice running entirely in the direction of oxidising the ore in a reverberatory furnace and smelting it in a blast furnace or water jacket.

It may well be conjectured that the ore hearth would still be holding its own to-day, seeing that it is admirably adapted for the smelting of pure, finely crushed lead ores, if workmen could be got to give the same care and attention to the smelting operations that they used to do, but it has been noteworthy that this is far from being the case. The men got into the habit of working their fires at longer and longer intervals, the make of lead decreased, and the proportion of fume produced increased, so that, by such practice, taken in conjunction with the steadily rising price of wages, the ore hearth is being gradually driven out of existence.

It need hardly be said that all improvements in general mining practice naturally helped the operations of lead mining also, and the same is true of dressing. It is probable that for many years but little improvement took place beyond the methods described by Agricola in Germany, and which no doubt in due course became known in this country, and which are about the same as those described by Glamil. It is on record that in Queen Elizabeth's time German miners were brought over to this country in order to instruct British miners in the more advanced methods then used on the Continent, and there is no reason to doubt that they brought with them such improvements as there were in dressing also. It is probable that until the eighteenth century the ore was crushed and hotched by hand; the only form of mechanical crushing in use up to that time—namely, that of stamping—is somewhat unsuitable to soft, highly cleavable ores like galena, and was never extensively applied to them. Crushing rolls were first devised in the North of England, probably in connexion with the lead mines, about 1800. The old round sieve jerked up and down in a tub of water was replaced by a larger rectangular sieve, worked by a compound lever or breakstaff, and in the early part of the nineteenth century these levers were worked mechanically. The modern jig, with moving piston and fixed sieve, appears to have been introduced in the Cornish Mines by Petherick about 1830, and it, too, was soon adapted to lead mining purposes. The importance of these various improvements in the methods of dressing are due to the fact that both the smelting hearth and the English reverberatory furnaces are only suited to the treatment of tolerably pure ore broken small, such as is produced by dressing operations.

All modern improvements in the production of lead, such as blast-roasting and smelting in huge water-jackets, like those which are in use in America to-day, are only intended for operations on a very large scale, and are quite unsuited to small mines. Mines of the former type do not in fact exist in Britain, and hence it is that British lead-smelting practice may be said to have become more or less stationary. A few works have adopted the modern methods above referred to, but without any conspicuous measure of success, owing to the fact that even if they purchase and import ores they are nevertheless restricted to a relatively moderate scale of operations.

Reference may perhaps be here made to the great improvements effected in this country in the process of desilverisation of lead. The first of these was due to Mr. Hugh Lee Pattinson, whose patent is dated 1833, depending upon the fact that when molten argentiferous lead is cooled slowly until a portion crystallises, the crystals contain much less silver than the portion which still remains liquid. This process was extensively employed until the introduction of Parke's process, patented by Mr. Parke in 1850, which is based upon the fact that if molten zinc is mixed with argentiferous lead, the zinc, solidifying first, abstracts the greater part of the silver, leaving the lead comparatively free from silver. This process is cheaper in its execution than the previous one, and therefore gradually displaced it.

An account of this subject would be incomplete without some reference to the output of lead in Britain. About 1830 the production was between 45,000 and 50,000 tons per annum, and there is reason to suppose that this was about 50 per cent. of the world's total output; in that year the United States was producing only on a small scale, its production being well under 10,000 tons. British production continued to increase pretty steadily, reaching its general maximum about the year 1855, after which it receded somewhat, rising again to about the same level in the year 1870, with an output of over 74,000 tons, and since that date it has been continuously declining. The following table shows the production of lead in Great Britain, the figures given being the quinquennial average output. Wherever known, the percentage which this output forms of the world's total production is also indicated:—

Period	Production of lead in Britain. Quinquennial average Tons	Percentage of world's production
1845/9	54,127	—
50/4	64,837	—
55/9	67,528	—
60/4	66,697	about 30
65/9	69,458	—
70/74	63,385	—
75/79	56,432	—
80/84	47,026	13·6
85/89	37,648	7·6
90/94	30,944	5·1
95/99	26,820	3·7
1900/04	27,507	3·1
05/09	22,339	2·2
10/14	18,890	1·7
15/19	12,099	1·2

The main fact that emerges from the study of these statistics is that Britain, which once exercised control over the lead market of the world, has now become a negligible factor. This is due not only to the rapid strides made by other nations, notably by the United States, but even more to the exhaustion of the British lead deposits, and there is no reason to suppose that Britain will ever again become a producer to be reckoned with in estimating the world's supply of lead. We have had our day!

SYNTHETIC ORGANIC CHEMICALS

We have received the ninth list of synthetic organic chemicals manufactured by the Eastman Kodak Co. of the United States. The present list contains the names of over 1500 chemicals which are in stock. Three qualities are supplied: "Eastman" chemicals, of the highest possible purity; "Practical" chemicals, not of the highest purity, but suitable for laboratory work; and "Technical" products as obtained from large-scale manufacturers and supplied in small quantities for experimental work. New chemicals are continually being added to the list, and it is worthy of note that many of the prices have been reduced owing, it is stated, to the increased demand and consequent lower cost of production. The practice of incorporating specifications of melting and boiling point ranges has been continued, and these data, obtained from actual laboratory observations, can be regarded as standards of quality below which these chemicals do not fall. The quality of certain chemicals has actually been improved, and directions are being prepared for some special reagents mentioned in an appendix to the list. The Eastman Kodak Co. will be glad to learn of new organic compounds available for purchase, of new sources of supply, or new chemicals required, as the company hopes not only to prepare materials, but to assist organic chemists. Copies of this list can be obtained on application to the Eastman Kodak Company, Rochester, United States.

THE ESTIMATION OF SODIUM HYDROSULPHITE

By R. W. MERRIMAN, M.A., D.Sc.

The manufacture of stable sodium hydrosulphite, $Na_2S_2O_4$, illustrates the characteristic energy of the German technical chemist in working at a problem for many years until final success is reached. Bernthsen and his collaborators, among others, continued the attack for over a quarter of a century, with the result that stable sodium hydrosulphite has been in general use for the past 18 years.

Many methods have been devised for the estimation of sodium hydrosulphite, but the only one which has survived critical examination for technical purposes is the Indigo-Carmine method. Synthetic "Indigo Pure" is constantly above 98 per cent. strength, and is readily purified by extraction with hot 90 per cent. phenol, the 100 per cent. indigo so obtained forming the standard upon which the strength of sodium hydrosulphite is based. An elaborate apparatus is necessary for the exclusion of air during the analysis, but the method offers no difficulties when a large batch of pure indigo has been prepared.

The Indigo-Carmine method satisfied all requirements so long as the use of sodium hydrosulphite was confined to vat dyers who found it necessary to do daily estimations. At the present time, however, sodium hydrosulphite is used for a large variety of purposes, *e.g.*, the estimation of oxygen in gases and the removal of oxygen from technical gases, the estimation of nitro-compounds and dyestuffs, the manufacture of dyestuff intermediates and drugs such as salvarsan, the bleaching of textile fabrics, straw, leather, glue, gelatin, sugar, glucose, soap, oils, fats, grain, flour, and asbestos. The chemist controlling such processes only requires to make an occasional estimation of sodium hydrosulphite, and a simple method of analysis has been searched for during many years. The following new method is based on standard iodine solution and no apparatus is necessary for the exclusion of air:—It has been known for a long time* that sodium hydrosulphite, in the presence of excess of formaldehyde, breaks up into a mixture of sodium sulphoxylate formaldehyde ($NaHSO_2$, CH_2O, ${}_2H_2O$) and sodium bisulphite formaldehyde ($NaHSO_3$, CH_2O, H_2O) according to the equation:—

$$Na_2S_2O_4+2CH_2O+{}_4H_2O=NaHSO_2,\ CH_2O,{}_2H_2O+NaHSO_3,\ CH_2O,\ H_2O.$$

The following method for estimating sodium hydrosulphite is based on the above fact:—

Sodium bisulphite formaldehyde is not acted upon by iodine in neutral or acid solution. Sodium sulphoxylate formaldehyde reacts with iodine in neutral or acid, solution according to the following equation :—

---

* (1) Baumann, Thesmer and Frossard, *Bull. Soc. Ind. Mulhouse*, 1904, **74**, 348; 2 *Z.f. Farb. and Textilind*, 1905, **4**, 292.

(2) Bazlen, *Berichte*, 1905, **38**, 1064.

$$NaHSO_2,CH_2O,2H_2O+4I=NaHSO_4+CH_2O+4HI.$$

It is clear, therefore, that the action of iodine on a solution of sodium hydrosulphite in excess of formaldehyde is to be represented by the equation :—

$$Na_2S_2O_4+2CH_2O+4I+3H_2O=NaHSO_4+4HI+CH_2O+NaHSO_3,CH_2O,H_2O.$$

That is, one molecular weight of $Na_2S_2O_4$ reacts with 4 atoms of iodine or 40 litres of N/10 iodine solution.

40,000 c.c. N/10 iodine=174·1 g. $Na_2S_2O_4$.

1 c.c. N/10 iodine=0·004352 g. $Na_2S_2O_4$.

The application of this method of estimation is described below.

Preparation of solution of hydrosulphite in formaldehyde—As the contents of a keg of hydros are apt to be shaken into layers of different strengths during transit, a proper sampler should be used in taking an average sample of the keg. The contents of the sample bottle should be shaken before weighing out the 10 grams required for the analysis. The 10 grams may be weighed out on an open watch glass if done rapidly. After some experience in weighing out this quantity of hydros, it can be performed accurately in a few seconds. The neck of a standard litre flask is cut off to within one inch of the graduation mark and is provided with a well-fitting rubber stopper; 20 c.c. of 40 per cent. formaldehyde is placed in the flask and distilled water is added, leaving room for another 50 c.c. of water. The flask is shaken to mix the formaldehyde uniformly with the water. The liquid in the flask is given a whirling motion by rotating the flask and 10 grams of the sample of hydrosulphite is poured into the flask down a dry funnel with a short stem. The funnel and watch glass are washed down rapidly with water, the volume is made up to the mark, the stopper inserted and the flask shaken vigorously. The whirling motion given to the liquid prevents the hydrosulphite sinking to the bottom and forming a cake. To obtain a uniform solution, it is necessary to shake the flask by inverting it repeatedly for five minutes, because of the small air space available.

Titration—About 100 c.c. of water followed by 20 c.c. of the hydrosulphite solution are placed in a beaker, using a standard pipette; 50 c.c. of N/10 iodine solution is at once added by a standard pipette. The light brown liquor is left for two minutes and the excess of iodine is back-titrated with N/10 thiosulphate solution with starch as indicator. No precautions are necessary to exclude air.

Examples—In each case 10 g. of the hydrosulphite and 20 c.c. of 40 per cent. formaldehyde were placed in the litre standard flask, 20 c.c. of this solution was taken for the titration and 50 c.c. N/10 iodine added as described above.

(1) *Works batch of sodium hydrosulphite testing* 99·5 *per cent. by the Indigo-Carmine method*

Thiosulphate required for the back-titration :

(*a*) 4.·55 c.c. N/10. (*b*) 4·60 c.c. N/10.
(*c*) 4·50 c.c. N/10.

Volume of iodine used=50−4·55=45·45 c.c., *i.e.*, equivalent to 45·45×0·004352 g. hydrosulphite. This is contained in 20 c.c. of the solution, in which 0·20 g. of the hydrosulphite was dissolved. The percentage content of sodium hydrosulphite$=\frac{45{\cdot}45\times4{\cdot}352}{2}=$98·9 per cent.

(2) *Mixing which has been reduced to standard strength with pure NaCl testing* 90 *per cent. by the Indigo-Carmine method*

Thiosulphate required :

(*a*) 9·15 c.c. N/10. (*b*) 9·00 c.c. N/10.
(*c*) 9·05 c.c. N/10. Mean 9·07 c.c.

∴ N/10 iodine used=40·93 c.c. Therefore, the percentage content of sodium hydrosulphite$=\frac{40{\cdot}93\times4{\cdot}352}{2}=$89·1 per cent.

It has been found, during an extended use of this method, that the action of formaldehyde on sodium hydrosulphite is an interesting "time reaction" and takes 15 minutes for completion with the quantities specified above. The solution of sodium hydrosulphite in formaldehyde should be left for 15 minutes before analysis. With 50 c.c. of formaldehyde (40 per cent.), the reaction is finished in about 5 minutes. A correction should be applied for the loss of hydrosulphite due to oxidation by dissolved air and by the small quantity of air in the flask below the cork, before the formaldehyde has had time to combine completely with the sodium hydrosulphite.

It is evident that this simple method is available for the testing of fresh commercial hydrosulphite which contains only sodium chloride in addition to the sodium hydrosulphite; but a technically useful method of analysis must have wider possibilities.

Sometimes the works chemist finds a partly used keg of "hydros" with the lid off and the contents smelling very strongly of sulphur dioxide and he requires to know how far the decomposition has proceeded. The alteration in weight of decomposed "hydros" is very small as the absorption of oxygen and moisture counterbalances the loss of sulphur dioxide. The following investigations, which are typical of a large number, prove that the products of decomposition do not interfere with the new method of estimation :—

(*a*)—320 g. of sodium hydrosulphite was spread out on a large dish and exposed to the atmosphere of a laboratory kept at about 60° F. From time to time the contents of the dish were mixed with a spatula and two separate 10-g. samples were removed for estimation by the Indigo-Carmine and iodine methods. The results obtained are tabulated below :—

Date	Weight of hydros	Removed for analysis	Indigo-Carmine method Per cent.	Iodine method Per cent.
Jan. 22	320	20	98·5	98·0
„ 26	298·8	20	90·0	89·1
„ 30	279·5	20	69·1	68·0
Feb. 2	259·3	20	51·8	52·2
„ 6	238·4	20	46·4	46·9
„ 9	217·8	20	41·5	42·0
„ 13	197·4	20	36·0	36·2
„ 16	176·9	20	33·2	33·5
„ 20	156·4	20	29·7	30·2

(*b*)—A sample of "hydros" received from Germany in a broken cardboard box had lost its power of decolorising Indigo-Carmine. 10 g. dissolved in dilute formaldehyde solution only absorbed 4 c.c. of N/10 iodine, corresponding to 0·17 per cent. of sodium hydrosulphite. 1 g. dissolved in water absorbed 23·1 c.c. N/10 iodine, corresponding to 12% $NaHSO_3$. 1 g. boiled with dilute HCl and $BaCl_2$ gave 1·0330 g. of $BaSO_4$, corresponding to 62·9% Na_2SO_4.

These results indicate that the iodine method may be applied to sodium hydrosulphite in any stage of decomposition. The solutions of decomposed hydrosulphite are perfectly colourless and clear, showing that free sulphur is absent. The agreement between the results obtained by the two methods proves the substantial absence of sodium thiosulphate.

SOME PROPERTIES OF MERCURIC IODIDE

By Dr. T. SLATER PRICE, O.B.E.

The enantiotropic forms of mercuric iodide, distinguished as they are by a marked difference in colour, have been the subject of extended investigations by many chemists, who have given their attention not only to the change of one form into the other, but have also extended their observations to the photosensitiveness of the two forms. As is well known the red modification, which consists of tetragonal crystals, is stable at ordinary temperatures, and the yellow modification, consisting of rhombic crystals, at higher temperatures, the temperature at which the one form changes into the other, the transition temperature, being somewhere about 127° (Rodwell *Phil. Trans.* 1882, **173**, 1125, and Gernez, *Comptes rend.*, 1895, **120**, 921, give 126°, as also Kastle and Reed, *Amer. Chem. J.*, 1902, **27**, 209. Reinders, *Zeitschr. physikal. Chem.*, 1900, **32**, 507, gives 129·5°, and Schwarz, *Preisschrift, Göttingen*, 1892, 129·3°).

Although the red modification is the stable form at ordinary temperatures and below 127°, the yellow form is readily obtained at these temperatures, it then changing more or less gradually into the red enantiotrope. It is a matter of common observation, for example, that when mercuric iodide is precipitated from a solution of mercuric chloride by the addition of potassium iodide the first formed precipitate is yellow. Bancroft (*J. Phys. Chem.*, 1896, **1**, 142) showed that when a solution of mercuric iodide in methyl alcohol (ethyl alcohol may also be used) is poured into water the yellow iodide is precipitated, and Gernez (*Comptes rend.*, 1899, **128**, 1516) found that if the red iodide is sublimed it condenses as the yellow form. The crystals which separate from a solution of the iodide in various organic solvents, *e.g.*, phenol, naphthalene, salol, vaseline, and many others, are yellow (Kastle and Clark, *Amer. Chem. J.*, 1899, **22**, 473; Kastle and Reed, *ibid.*, 1902, **27**, 209). The effect of gelatin in favouring the formation of the yellow modification has been known since Lüppo-Cramer (*Zeitschr. wiss. Phot.*, 1903, **1**, 50) first investigated the preparation and properties of photographic emulsions of the yellow variety. Ostwald, in a book notice (*Zeitschr. physikal. Chem.*, 1912, **79**, 253) makes a statement which indicates that when precipitated from alcoholic solution in the presence of a colloid, the yellow form can be preserved for a long time; presumably the colloid referred to was gelatin, since the emulsion was used to make a paper sensitive to light. Newton Friend (*Nature*, 1922, **109**, 341) has recently called attention once more to the effect of gelatin in stabilising the yellow form.

These effects are examples of Ostwald's rule that when a substance is formed which is capable of existing in more than one modification the least stable modification is formed first; this may then change, sooner or later, into the stable modification.

The yellow mercuric iodide which results when the alcoholic solution is poured into water may remain unchanged for days; when exposed to light, however, the change to the red modification is very much accelerated (Ostwald, *Zeitschr. physikal. Chem.*, 1897, **22**, 308). Ostwald again refers to the accelerating action of exposure to light in *Zeitschr. physikal. Chem.*, 1912, **79**, 253, as also does Newton Friend (*loc. cit.*), but these were not the first observations of this kind, since the change is mentioned by Weber (*Pogg. Ann.*, 1857, **100**, 131), Schiff (*Ann. d. Chem. und Pharm.*, 1859, **111**, 371), Reynoso (*Comptes rend.*, 1854, **39**, 696), and Selmi (*Cimento*, 1855, **1**, 183).

As distinct from the change of the yellow into the red modification, it has long been known that mercuric iodide is photosensitive. The earliest observations are probably those of Hunt (*Researches in Light*, 1844; compare Lüppo-Cramer, *Zeitschr. wiss. Phot.*, 1903, **1**, 50), who found that a film of mercuric iodide on paper became brown on exposure to light. Slater (*Chem. Gaz.*, 1852, **10**, 325) showed that the brown coloration was especially favoured by the use of blue light. Sulc (*Zeitschr. anorg. Chem.*, 1900, **25**, 399) observed that when mercuric iodide is dissolved in alcohol, chloroform, or ethyl bromide, and the solutions exposed to light, free iodine and mercurous iodide are formed. Naturally, the fact that mercuric iodide is photosensitive led to its investigation as a possible substitute for the silver haloids in photographic emulsions, and in this connexion a number of papers have been published by Lüppo-Cramer (*Zeitschr. wiss. Phot.*, 1903, **1**, 50; *Koll. Zeitschr.*, 1911, **9**, 22; 1912, **13**, 151; 1913, **13**, 151; 1915, **16**, 11; 1917, **22**, 77; *Phot. Korr.*, 1904, 403; 1907, 130; 1909, 191; 1914, 112) and by Kropf (*Phot. Rund.*, 1910, **24**, 185; *Phot. Chronik*, 1910, 436; *Phot. Korr.*, 1914, 640). A fine-grained emulsion of the yellow iodide is obtained by adding a solution of mercuric iodide to a solution of potassium iodide containing gelatin, the temperature being 50°. After the addition of more gelatin the whole may be set to a gel on cooling, and then shredded and washed to remove soluble salts, after which it may be coated on plates as with an ordinary photographic emulsion. If the emulsion obtained on mixing the salts is boiled, it gradually turns red and the precipitate readily settles on standing, showing that the grain has become less disperse.

If a concentrated solution of gum arabic is added to a liquid emulsion in gelatin of the yellow mercuric iodide, rapid settling takes place, the deposit consisting of larger particles of the red iodide. Gum arabic thus appears to act differently from gelatin, and, in accordance with this, if an emulsion is made from mercuric chloride and potassium iodide as above, but using gum arabic instead of gelatin, the red iodide is obtained; this may then be "set" by the addition of gelatin, shredded, washed, etc. The effect of the gum arabic depends, however, on the temperature. If the emulsification takes place at 80° yellow mercuric iodide is produced, but the crystals are much larger than those obtained with gelatin at 50°; gelatin also gives the large yellow crystals at 80°.

These emulsions are not nearly so sensitive photochemically as those of the silver haloids. The red emulsion is more sensitive than the fine-grained yellow emulsion, whilst the yellow emulsion made at 80° is not very sensitive in comparison with the others.

It has already been mentioned that the change from red to yellow mercuric iodide is accelerated by exposure to light, and Ostwald states that when he precipitated mercuric iodide from an alcoholic solution in the presence of a colloid he was able to make a sensitive paper with the product, which, exposed under a negative, gave a red print on a light background. When, however, plates coated with yellow emulsion made according to the method given above are exposed to the light until a print-out effect is produced, a brown colour due to loss of iodine is obtained, and not a red colour. The following experiments of Lüppo-Cramer throw some light on this apparent discrepancy. If the yellow-white emulsion produced when a saturated alcoholic solution of mercuric iodide is poured into water is exposed to direct sunlight, it changes colour in a few minutes and the red mercuric iodide formed rapidly sinks to the bottom, showing that it is of a much less dispersity than the yellow iodide. If some of the freshly-prepared emulsion is allowed spontaneously to evaporate in a Petri dish and then examined when dry, it is found that if it was exposed to the light during evaporation there is a number of red crystals among the yellow. These red crystals are much larger than the yellow ones and each one is surrounded by a clear space, showing that it has been formed as the result of Ostwald ripening.* If the evaporation takes place in the dark only the smaller yellow crystals remain, there being only an occasional red crystal. If the dry yellow deposit is then exposed to light there is no increase in the size of the particles and no change to red, the ordinary photochemical brown colour appearing.

Ostwald ripening such as that indicated above can only have taken place as long as there was some of the solution containing mercuric iodide present; since the yellow emulsion coated on plates has been well washed and dried, Lüppo-Cramer says that the explanation as to why it does not turn red on exposure to light is obvious.† If the plates are exposed to light while under water they turn red in one to two hours, and then fix out glass-clear with thiosulphate.

The complex (or double) salt formed between mercuric and silver iodides is only very little sensitive to light (Lüppo-Cramer, *Eder's Jahrb.*, 1904, 12); this is remarkable, since each of the components is fairly photosensitive.

---

* Strictly speaking this is not a simple Ostwald ripening, since it is not merely the growth of a large crystal at the expense of a smaller one, but the growth of a stable at the expense of an unstable modification. At ordinary temperatures the red iodide, being the stable form, will have a lesser solubility than the yellow iodide and therefore, once the crystal of the red iodide is formed, it will grow at the expense of the yellow iodide crystals surrounding it, the growth taking place through the agency of the surrounding solvent medium (compare also Sheppard and Trivelli, *The Silver Bromide Grain of Photographic Emulsions*, p. 62). The effect of the solvent can be shown by the following experiment, due to Lüppo-Cramer. A microscope slide is coated with a 10 per cent. solution of gelatin containing 1 per cent. potassium iodide. When the film is set, a drop of 4 per cent. mercuric chloride solution is placed in the centre. In the dark a ring of yellow mercuric iodide is first formed, but after several hours the outer zone turns red, the width of the zone gradually increasing. This is because of the diffusion towards the ring of the potassium iodide in the surrounding film of gelatin. If the experiment is done in the daylight, the change from yellow to red takes place much more quickly than in the dark.

† An explanation as to why growth of the crystals does not take place may be obvious, since there is insufficient solvent left in the dry plate for ripening to proceed, but this does not explain why a red colour is not produced. An explanation is still wanting as to why light accelerates the change from the yellow into the red iodide.

THE PROGRESS OF THE BRITISH CHEMICAL INDUSTRY SINCE 1914

By HERBERT LEVINSTEIN, M.Sc., Ph.D.

(*Continued*)

There are two striking developments of the war years which do not directly affect production, but which throw a vivid light on the greater importance attached to chemical industry and to research by the public. The chemical industry has grown strong enough, and big enough, and wise enough to form an Association which Mr. Woolcock has made a power in the land. The chemical industry is no longer deaf and dumb. The Association of British Chemical Manufacturers can speak with authority on behalf of the whole industry, and has in fact rendered in all respects remarkable service to its members. Affiliated to the A.B.C.M. is the Association of British Chemical Plant Manufacturers. To-day the plant manufacturers, through their Association, are standardising plant, and can render services to chemical manufacturers which would have been impossible before the war. I suppose that before the war the demand for the chemical industry, at least the organic chemical industry, was too small to interest many of the large engineering concerns. Certainly we had the greatest difficulty in getting even autoclaves.

The second striking feature is the creation of the Department for Scientific and Industrial Research. Who could have dreamt that Whitehall, before the war, would subsidise research and do it not without insight? Under the auspices of this Department no less than twenty-four Industrial Research Associations have been formed, of which twenty-two are licensed by the Department and received over £86,000 in grants during last year. The wielder of the ruthless axe refrained from striking here.

Broadly speaking, the work of the Department and of the Research Associations with which they collaborate is to ensure the best utilisation of our natural resources and of the raw materials which we buy from abroad for our staple industries with a view to increasing the efficiency of those industries and enlarging the demand for their products in customer countries.

This work does not replace that of private firms, but is complementary to and ought to stimulate it. There is a radical difference between industrial research carried out by a company and that by a Research Association or by a Department of State. Practically the question of patents is the fundamental distinction. Patents taken out by chemists who receive part of their emoluments from the Department belong, if I understand the position rightly, to the Government. Patents which may be taken out by a Research Association would, I presume, be available for all subscribers, and could not easily become a profitable monopoly for any one member. For this reason it appears likely that in the future, as in the past, the Dyestuffs Industries and the allied Fine Chemical Industries will be the main source from which chemical discoveries will be transferred from the laboratory to the factory. The Dye Industry will remain the key industry to chemical inventions.

Most of us in this Section take a very considerable interest in the work of the Fuel Research Board, which is maintained by the Department for Scientific Research. Any invention which would enable us more economically to utilise our coal would be of great benefit, particularly if it could be introduced widely and quickly and at a reasonable cost. There is one obvious weakness which could be remedied without research. I refer to our practice of fetching coal from the pit to the mills by road or by rail, instead of generating our power at the pit mouth and delivering power to the mills through high-tension wires. The amount of useless hauling of full and empty waggons is wasteful and a blot on our industrial system. The absence of a network of wires carrying high tension current in this country is surprising when you have seen the practice abroad. Research should surely be preceded by utilisation of known improvements. To search for the sublime in the unknown and miss the obvious is not an uncommon practice. Industrial research is not much good, unless you propose to find the means of carrying discoveries into effect, and here you have an obvious weakness well enough known but quite neglected.

THE DYESTUFF INDUSTRY, 1914

I have left the Dyestuff Industry till the end. The last statement issued by the A.B.C.M. deals in a very lucid manner with the present position. I should like to qualify one remark picked out of this admirable publication. I am quite sure that Mr. Woolcock will not mind my commenting on the statement that 10 per cent. of the dyestuffs required by the various consuming industries were of British origin in 1914, and that of this 10 per cent. many were merely *foreign dyestuffs mixed in British works.* It does not give a just impression of the pre-war British Dyestuff Industry.

Prior to the war about 80 per cent. of the dyes consumed in this country came from Germany, about 10 per cent. from other countries, and 10 per cent. were manufactured (I do not mean mixed) in Great Britain. My own company had a considerable share of the British production and, *pace* the A.B.C.M., the dyes they sold were made in their own factory, many of them their own inventions. They did not purchase dyes to mix them, they sold their dyes wherever they could find a purchaser. America, Italy and the East took about as much as Great Britain. The 10 per cent. supplied to Great Britain did not include the whole British production. Nor was the range of dyes contemptible. At our own factory we made about 160 chemically different dyes. Our range of azo colours and sulphur colours compared favourably with those of foreign firms. On the other hand, there were great gaps. Why had we these gaps ? Surely because it was difficult to introduce and sell a new range of dyes and make any money out of it. As the Fine Chemical Industry, so in the Dyestuffs Industry, the whole war development, with very little qualification, is due to those who carried on the industry before the war. They were not mushroom firms. Surely any thinking person must know that the rapid extension is solely due to the existence of these firms and their experience. We have not created these industries, but those who were in them have expanded. If you see what kept the industry back before the war, you will see that it can develop in this country now that these inhibiting conditions no longer exist. The prices at which British dyestuffs were sold on the whole were lower than those at which the Germans sold their dyes ; the quality of the corresponding product was equal to that of the Germans, otherwise the dyes could not have been sold at all. The greater range of the German Dyestuffs Factories and the great prestige which they enjoyed enabled them to dominate the markets. Their commercial organisation and commercial propaganda which greatly impressed the consumer made it extremely difficult to find a sale for the British-made product. The main pre-war difficulty in this industry was not on the manufacturing side but on the sales side. Owing to the large number of new products which were constantly appearing from German works, consumers felt that they must keep in touch with the German firms. Many of them did not think that they would miss new products if they did not trouble to have an account with a British house. There was almost up to the war severe price cutting between the two big German groups, and these prices had to be accepted by the British makers.

My own firm had been since 1907 an object of very special dislike on account of the active part taken by my father in bringing about a change in our patent law with a view to compelling the Germans to manufacture in this country. When the Act of 1907 was passed, the Germans erected plant at Ellesmere Port and Bromborough Port, and to this we owe our present indigo factory (much enlarged) and the Mersey Chemical Works owned by Messrs. Brothertons.

In 1907 a great proportion of our business consisted in the manufacture of intermediates which were supplied to the German dyestuffs factories. We did not manufacture these intermediates into dyestuffs. Why ? The simple truth was that the sales organisation of the German factories rendered it impossible to find a market for the dyes, and this fact made it possible for us to find a market in Germany for our British intermediates.

It will perhaps surprise some of you to know that such products as Gamma Acid, H. Acid, and Cleves Acid were made in England over twenty years ago and sold to German dyestuff factories, and were afterwards re-exported to England as components of German dyes. Naphthylamine and Naphthionate were very important products to us. Their purity was acknowledged. Most German Congo Red, Benzopurpurine and Wool Black, for instance, were made from these intermediates. If Yorkshire buyers wanted only German Wool Black, or if Indian buyers wanted only German Congo, the intermediates came largely from Blackley. The Germans cut off all orders we got with a view to punishing us for the action taken in the reform of our patent laws. This action threw large plants out of commission and caused heavy losses. The undercutting, "according to plan," by the Germans in all staple products made it difficult to retain, and more difficult still to expand business in dyestuffs. You will see, therefore, that the position of the comparatively small firm opposed by the German Collosus was not easy. Yet what was the result ? In a few years the loss was made good and considerable profits were earned. How was this done ? The answer is by successful research, carried out, it is true, on a most economical basis. No combine, however willing to crush you, can prevent you if you know how to discover a new product, and if it is new and useful the public can be persuaded to buy it at a good price.

I have not such detailed information with regard to other companies—Read Holliday and Sons, the British Alizarine Co., and the Clayton Aniline Co. To me, quite frankly, the description of their pre-war work seems inadequate. One may easily form an erroneous judgment from the sentence I have just quoted. It seems important to me to remember that these firms enjoyed no kind of protection, and yet they succeeded in holding their own. The contemptuous way in which the pre-war British Dyestuffs industry was regarded by many people was the result of German propaganda, and I am afraid this opinion had become firmly embedded in the public mind.

The Germans were very successful in two distinct pieces of propaganda. First, they impressed all Europe with the idea of the invincibility of the German Army. This was an axiom, and profoundly and favourably affected German diplomacy before and during the war. Secondly, they succeeded in impressing all the world, and not least England, with the idea of the utter futility of attempting to compete with the German dyestuffs factories. They succeeded in getting the consumer to believe that it was an absurdity to get supplies from British sources. Both of these axioms have been shown to be false, but I believe that both were so firmly fixed in the minds of the people that nothing but the defeat of the German Army would have shaken either. The war has broken the continuity of German supplies. Every consumer has been forced to buy elsewhere, and the German goodwill is therefore diminished. That in itself is a powerful help to those outside the German I.G., and encouraging to those now carrying on our dyestuff industries.

THE DYESTUFF INDUSTRY, 1923

The A.B.C.M. statement tells us that 80 per cent. of the dyes now used in the country are of British make, and that they are wholly British uncontaminated by any made-in-Germany organs in their anatomy. That is excellent. We may add to this the reflection that the dyers of Great Britain are able to give the same guarantees of fastness to their customers, now that they use 80 per cent. of British made dyes, as they were able to give prior to the war when they used a predominating proportion of foreign dyes.

I would also point out that if I may judge from the share values or from the dividends paid by the large textile combines which use dyes, that the substitution of British dyes for German dyes has not produced such financial disaster as was predicted by some of the opponents of the Dyestuffs Act.

The first person in public life to recognise the importance of the dyestuffs industry, both in peace time and in war time, was Mr. Runciman. If we examine what did happen exactly after the war, we shall see what progress was made at two critical periods—1919-20 and in 1923 :—

"No one can tell" (said Mr. Runciman) "what exactly will be the position after the war is over. Of this I am certain, if we go on being dependent in a large portion of our textile trade, whether wool or cotton, upon supplies which Germany has the power to cut off whenever she pleases we leave these cotton and wool industries in a state of peril."

What did happen after the war ? Were our textile industries left dependent upon Germany ? Were they in a state of peril ? Let us see. In 1913 the Dyestuffs Industry in England supplied about 10 per cent. of the British consumption, which amounted in round figures to rather over 20,000 tons. The factories were comparatively small, and the number of chemists proportionately few. By Armistice Day the two principal companies, already loosely united, employed some 7000 persons, nearly 300 academically trained chemists—an unheard of number in this country. During the two years following the Armistice over 25,000 tons of dyestuffs manufactured by this British company alone went into consumption in Great Britain. I am not talking of the production, nor of the sales, but of just the quantity actually consumed in Great Britain.

The extraordinary prosperity in the textile trades at that period had its aftermath in the slump. But in 1919 the employment provided by these trades, and the money brought into this country as payment for exports, were factors without which this country would not have readily recovered from the paralysis of war. I do not know the total value of these exports, but the exports of printed and cotton dyed piece goods alone during 1919-20 amounted to 270 million pounds in value. What would have been these exports had the 25,000 tons of British made dyestuffs not been available ?

In October, 1920, the British Dyestuffs Corporation (and remember there are other important dyestuff makers in this country to carry out this work) employed some 8000 people with a yearly wage roll of £1,600,000. This company used 4000 tons of coal per week, 1000 tons of pyrites and corresponding quantities of heavy chemicals and raw materials. These figures will, I think, be considered large in this country, where we are not so familiar with very large plants, but of course they are small compared with the aggregate of the German I.G. Suddenly in October, 1920, the slump fell upon the country. The position was made much worse by four factors. The German production revived, considerable quantities of German dyes were imported as reparations, the Sankey judgment temporarily removed all protection from the home producer, and the rapid external depreciation of the mark temporarily made it difficult to compete with Germany in neutral markets. Stocks fell in value, large sums of money were lost, and the production of British companies fell down almost to prewar figures.

THE RUHR

I cannot imagine a more delicate political situation than that arising out of the French action on the Ruhr. Fortunately our negotiators were free from anxiety as to the effect any action taken by the French on the Ruhr might have in restricting a supply of dyestuffs. You know exports from the German dye factories are prohibited by the French, except under licence, while the German Government forbids these firms to make application for licences. What will be the outcome no one can tell, but this I do know, that there will be no operatives thrown out of employment here if Germany fails to maintain her production of chemicals.

It seems clear that if our position in the Dyestuffs and Fine Chemical Industries to-day were no better than it was in 1914 we should have to consider what would happen to the textile trade of this country *if* the supply of German dyes were cut off in Germany by troubles on the Ruhr. If we do not have to consider this we have a measure of the progress made. I am careful to express no political opinions. I do not wish to be misunderstood. I am making the one comment on the Ruhr situation as it presents itself to me, viz.: That in fact any restrictions in the output of German dyes is a matter of no political importance, whereas had we not established this industry to the extent which we have done, the possible effect of French action on German chemical industry would have been a factor of first-class political importance. I do say that our textile trade is not to-day left in a "state of peril."

The British Dyestuffs Corporation

I sometimes think that nothing could more clearly show the extraordinary change in the views held on the British Dyestuff Industries since 1914 than the formation of the British Dyestuffs Corporation. For sixty years you carry on; for years you point out the menace which in threatening you, threatens the textile trades. Nobody takes the least interest in your work. Suddenly in 1914 it is found to be a fundamental part of the national fabric. Who would have thought it possible in 1914, that in March 1918, you would be pressed at a crucial point in our history to amalgamate your business on the ground that it was vital to our peace negotiations?

The B.D.C. was formed entirely on national grounds, so far as we were concerned, solely owing to the pressure put upon us by Ministers. The initiative was taken by the President of the Board of Trade. That initiative would not, I may say, have been taken by ourselves, nor would it have been acceded to on any other grounds save those put forward by the President. It is, I think, rare in our industrial history that Governments have practically compelled an old-established manufacturing company to join a concern in which the Government were interested, because they felt that such co-operation was vital to the State. That, however, was the case in the dyestuff industry at the critical ending period of the war. The terms of the merger are described in an official publication, "Report on Dyes and Dyestuffs," dated May 18, 1921. Perhaps someone can tell a fairer way than the method therein described. We knew of none. We were making no commercial bargain. We did desire that the distasteful course we took would give the results the Government desired. It was necessary to spend large sums of money in construction when everything was dear. That was the essence of the job. We were definitely promised a prohibition of German imports into this country for a period of ten years after the war, to say nothing of a similar protection which it was expected would be afforded by India and some other countries. Without this definite pledge there would have been no amalgamation. As you know, the Government endeavoured to carry out their pledge, but, as you also know, the imposition of an Order in Council was shown to be illegal by the Sankey judgment. As the Government did not venture to appeal against this judgment, we may conclude that their method of carrying out their promise had not been examined by their legal advisers with the care we might reasonably expect. On the other hand, we took upon ourselves the gigantic burden only on the clearest understanding that the pledge would be kept. We carried out our contract. There was no difficulty at the Peace Conference. The textile trades were not "left in peril" in the boom years owing to dependence on a non-existent supply of German dyes.

The Sankey judgment in the peculiar circumstances of the time involved us in heavy losses at a critical period of the development of this industry. You must remember that the British Dyestuffs Corporation manufactured not less than 75 per cent. of the dyestuffs used in this country. Clearly the passing of the Dyestuffs Act in 1920 did not re-establish the status quo. You will see the extraordinary importance attained by this industry in Germany not merely in war but politically, for in this and in many other ways we know of, the German supremacy was a strong weapon wielded by German diplomacy. The Government desired the formation of the British Dyestuff Corporation, when they took on their own initiative steps to form it, because they desired to strengthen the hands of our diplomatists when the time came to discuss the terms of Peace.

I do not think that many people are aware of how this Corporation came to be, how definitely the pledge was made, and how inadequately the Dyestuff Act fulfilled it. I have always found the opponents of the Dyestuff Act to be as fair-minded men as any I know, and I cannot, therefore, imagine that people advocating a repeal of the Act are aware of the circumstances.

Conclusion

Now, we have not the slightest interest in industries which can only live in this country under Protection. Our dyestuffs industries, our organic chemical industries cannot be static. They live by research and this implies two things:—

1. Constant growth, because they make inventions which require to be translated into manufacturing processes.
2. World markets, because new inventions must be exploited and sold wherever a consumer exists.

It follows clearly that this industry cannot live as we wish it to live on a protected home market, and that we do not require permanent protection. If I have shown you that we have created something vital, that we may help to prise open the door of the unknown, I am satisfied. The world is searching for new industries. We have created chemical industries since 1914, but not *new* chemical industries, for they already exist in Germany. These are dependent on, and fruitful of, inventions. As parent industries we regard them hopefully. It is to their children that we look for the real benefits from our 1914 industrial effort in applied chemistry.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

THE OLD CITY COMPANIES with their centuries of tradition behind them form a never-failing source of interest to an old journalist. I have been renewing my acquaintance with some of them recently, and the more I see of them the more I feel they have a part to play in connexion with industry to-day. Whether there is any such desire among the liverymen I know not, or whether there is a sufficient sprinkling left in the Companies of persons connected with the craft they represent may be doubtful, but I believe there is still a desire to do something useful. They have been and still are extraordinarily liberal with the funds at their disposal. The Goldsmiths' Company is one of the twelve "great" companies which still has a close connexion with the trade. To dine in their very fine hall is still one of the desirable functions, an invitation to which is never refused. The Armourers and Brasiers, who also keep a good table, are quite naturally, owing to changes in the method of warfare, not as much in evidence as formerly, but I believe they still have the right to confiscate any piece of armour which is found not to bear the mark of the Company.

THE TWO COMPANIES most closely connected with Chemical Industry are the Salters and the Dyers. The former is also one of the twelve "great" companies and has for many years contributed most generously to the higher education of chemists, years ago in the form of scholarships and more recently by the foundation of the Salters' Research Institute of which our old friend Dr. M. O. Forster was the first Director. It is a very ancient company and dates back I think to the fourteenth century. I remember once seeing there a bill for a dinner for fifty persons given so many years ago that the total amount came to £1 13s. 2½d. and it was a very fine dinner. I believe the Company keeps in touch with the Industry through a Committee of the Council of the Association of British Chemical Manufacturers. I was once told that the Company never seeks the advice of that Committee, except on an afternoon and always invites the Committee to lunch first.

THE DYERS' COMPANY is not one of the "great" twelve, but it is the next best thing to it being the thirteenth in order of precedence of the City Companies. One of the things which has always struck me when I have dined with this Company was the devotion of its liverymen to the old guild. Of course all liverymen are proud of the company to which they belong, but in the case of the Dyers, this devotion amounts almost to a religion. The Company does not contain more than the average number of those now connected with the art of dyeing, but there is nevertheless a keenness to follow all that is going on in the colour-using and colour-making industries, which makes me wonder why this ancient guild has not hitherto taken a part in helping this country to develop these industries in recent years. There is still an important function for the City Companies to perform if they can only be kept in touch with the industries, which have developed out of the arts and crafts which formerly they fostered and controlled.

THE DINNER of the Society of Dyers and Colourists held at Bradford last week was a much more enjoyable affair than is usual with public dinners. I think this was largely due to the fact that a time-table had been carefully prepared and was rigidly adhered to by the speakers. Sir William Alexander in a speech from which all surplusage was eliminated set a good example and Mr. Woolcock managed to say all he had to say in just under ten minutes. The presentation of the Perkin Medal to Mr. Charles F. Cross was made by the President (Mr. S. J. Pentecost). The medallist's health was proposed by Mr. Sutcliffe Smith in whose speech and that of Mr. Cross we had one more example of the amount of pleasure a speaker can give his audience if he only knows what he wants to say before he gets up to say it. All of which contributed largely to our enjoyment.

A JOURNALIST who has to attend a large number of dinners in the year gets ample time for studying the methods of after-dinner speakers. Indeed, were it not for the fact that there is always some amusement to be got out of this the business of attending so many dinners would be intolerable. I suppose Dr. Forster when at his best was one of the wittiest after-dinner speakers we have had and I could rarely detect any signs of previous preparation. Our President also seldom uses a note and manages to introduce a lot of dry humour into his speeches. Mr. Cross's speech, after receiving the Perkin Medal, seemed to me to be a model for such occasions. A half sheet of notepaper with just the pencilled outline of the main theme—the discovery of viscose. A reference to the presence of the son of the man whose name is commemorated in the medal, a modest word of thanks and the result—a well-satisfied audience. Mr. Sutcliffe Smith is the type of speaker who carefully prepares his speech *in extenso* and brings it with him to the dinner. This is a habit, and quite unnecessary, as he speaks equally well if you give him anything else to hold in his hand.

FORTHCOMING EVENTS

Mar. 23. Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 9 p.m. "Life History of an Alpha Particle from Radium," by Sir E. Rutherford.

Mar. 23. University College, Nottingham, at 8 p.m. *Sir Jesse Boot Foundation Lecture.* "Evolution in Chemical Industry," by Prof. F. S. Kipping, Ph.D.

Mar. 24. Royal Institution of Great Britain, 21, Albemarle Street, W. 1, at 3 p.m. "Atomic Projectiles," by Sir E. Rutherford.

Mar. 27. Society of Chemical Industry, *Birmingham and Midland Section*, at the University, Edmund Street, Birmingham, at 7 p.m. (1) "The Reaction Between Ammonia and Sodium Hypobromite," by D. R. Nanji, M.Sc., and W. F. Shaw, M.Sc. (2) "Some Studies in Catalytic Hydrogenation," by E. J. Lush, M.A.

Apr. 9. The Institution of Rubber Industry, Engineers' Club, Coventry Street, Piccadilly, W. 1. "Rubber Pigments," by Dr. D. F. Twiss.

Apr. 10. Society of Chemical Industry, *Birmingham and Midland Section*, the University Buildings, Edmund Street, Birmingham, at 7 p.m. "Some Observations on the Activated Sludge Process," by F. R. O'Shaughnessy, A.R.C.Sc. "Some Studies in Catalytic Hydrogenation," by E. J. Lush, M.A.

Apr. 10. Institute of Metals, *Birmingham Local Section*, the Chamber of Commerce, New Street, Birmingham, at 7 p.m. Annual General Meeting.

Apr. 10. Institute of Metals, *North-East Coast Local Section*, Electrical Engineering Lecture Theatre, Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. Annual General Meeting.

Apr. 11. The Institution of Electrical Engineers, *Wireless Section*, Savoy Place, Victoria Embankment, W.C. 2, at 6 p.m. "Magnetic Drum High-Speed Recorder and Key Transmitter," by Dr. N. W. McLachlan.

Apr. 12. The Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C. 2, at 6 p.m. "The X-Ray Examination of Materials," by A. G. Warren.

Apr. 12. Society of Chemical Industry, *Ottawa Section*, University Club, Elgin Street, Ottawa, at 8 p.m. "Electrolytic Iron," by R. J. Trail.

Apr. 12. Institute of Metals, *London Local Section*, Institute of Marine Engineers, 85-88, The Minories, Tower Hill, E. 1., at 8 p.m. Annual General Meeting, followed by a paper on "The Surface Tension of Metals," by S. W. Smith, D.Sc.

Apr. 13. Society of Chemical Industry, *Liverpool Section*, Muspratt Lecture Theatre, the University, Liverpool, at 6 p.m. Meeting of the Chemical Engineering Group.

Apr. 26. West of Scotland Iron and Steel Institute. Annual General Meeting.

SOCIETY OF CHEMICAL INDUSTRY

CORRESPONDENCE BETWEEN THE PRESIDENT AND THE CHAIRMAN OF THE AMERICAN SECTION

The Chairman and Committee,
American Section of the Society of Chemical Industry

Gentlemen,—In wishing you the compliments of the season I trust that you will allow me to add the hope that 1923 will see the American Section of our Society more prosperous than ever before.

We, on this side, appreciate to the full the loyalty which you have shown to the Parent Society, and assure you that at no time has our interest in your Section been greater. The interchange of visits by individuals, the official visit paid to you during 1921, and the hospitality offered by the Chemists' Club and the Chemical Industry Club, have all helped to cement that alliance between the two great Anglo-Saxon nations which is essential for the well-being, indeed, for the very existence of civilisation. Chemists have a very special part to play in the re-establishment of peace and prosperity and high ideals of social service among mankind, and it is only by the chemists of America and Britain standing shoulder to shoulder that we can hope to achieve our ideals.

I trust that many members of the Society will be interchanging visits during 1923 to our mutual advantage, and remain, Yours fraternally, (Signed) E. F. Armstrong,
President

My dear Dr. Armstrong,—I took pleasure in presenting to the Executive Committee of the American Section at its last meeting your letter of good wishes for 1923. The Committee and I wish to express best wishes for the coming year to you personally and to the Society.

We want, also, to express our appreciation of the changes in publications which are now taking place, and which promise so much for the future of chemical industries in the English-speaking countries.—Very sincerely yours,

Ralph H. McKee

NEWS FROM THE SECTIONS

BIRMINGHAM AND MIDLAND SECTION

Dr. E. B. Maxted presided at the meeting held on March 6, when Dr. J. Newton Friend read a paper on "The Influence of Emulsoids upon the Velocity of Chemical Reactions."

Dr. Friend said that the study of colloids and emulsoids, particularly in relation to adsorption, was very fascinating, and although some advance had been made in recent years, we had as yet only begun to touch the fringe of the subject. An emulsion was a system of two liquid phases, the first of which was continuous, and the other discontinuous or disperse. If the disperse phase consisted of very minute particles of diameter, say, of one-millionth to one ten-thousandth of a millimetre, the system was termed emulsoid. Emulsoids could be prepared directly by adding a suitable continuous phase to a gel and then applying heat, *e.g.*, as in the preparation of glue. An indirect method was to dissolve a suitable gel in a solvent and then pour it into another liquid in which the original gel was not very soluble. For instance, gamboge was dissolved in alcohol and a few drops of the solution poured into excess of water. Emulsoids prepared in that way were used by Perrin in his classical researches on the Brownian movement. Freundlich's adsorption law was explained, and it was pointed out that it was really a special case of the better-known partition law. If X was the amount of emulsoid adsorbed and C the final concentration of emulsoid, $X=K\sqrt[n]{c}$ where K and N are constants; then $\log X=\log K+\frac{1}{n}\log C$, and if a graph was drawn with log X plotted vertically and log C horizontally, the data should lie on a straight line if the law was obeyed. It was often not easy to determine the value for X because it is so small. Langmuir had suggested that the adsorbed layer on a given surface was only one molecule thick; but if it was assumed that the retardation of chemical reaction was proportional to the amount adsorbed, relative values for X could be obtained. This explained why the setting of plaster of Paris was retarded by the addition of gum arabic, a fact well known to modellers. The rates of solution of salts in water and the rates of crystallisation of salts from aqueous solution were similarly retarded. The characteristic feature of emulsoids was their power of being adsorbed; and illustrations were given showing the influence of emulsoids on the course of some familiar chemical reactions. Although emulsoids and gels generally retarded chemical action, one interesting case was that in which the gels acted as catalysts—namely, in accelerating the setting of linseed oil. This was effected by the presence of such gels as size, glue, etc., and was probably due to their power of handing over moisture to the unsaturated acid radicals in the oil, the drying of linseed oil in that case being really a wetting.

The chairman commented upon the big advance that had been made in recent years in the study of colloids, and on their employment in electrolysis. Mr. G. King said that greater stress should be laid upon the study of the degree of dispersion of the colloid. Much research lost its value because the degree of dispersion was not stated in the published results. Dr. Parker pointed out that emulsoids were a source of much trouble in the manufacture of carburetted water-gas. A high-boiling petroleum oil was used, and part of the oil was converted into tar, much of it being obtained in the form of an emulsion in water, which had generally to be thrown away, though it was sometimes mixed with coke dust and used for firing boilers. The trouble was how to get rid of the emulsion. Mr. F. R. O'Shaughnessy said that contributions such as that of Dr. Friend were most important because they enabled one to get a better general view of the laws governing the colloidal state. Dr. Maxted had suggested that men were living colloids, but recent work suggested that the living organism was a non-colloid, although containing an immense number of colloids in practically every condition. Mr. Carter observed that colloids could accelerate reaction velocities; the addition of a colloid in the electrolysis of metals, particularly of zinc, had a useful effect.

BRISTOL SECTION

The Annual Dinner was held on March 15 at St. Stephen's Restuarant. Mr. W. Jones presided, and those present included Mr. W. Windus (the guest of the evening), Prof. F. E. Francis, Dr. Rixon, Messrs. R. Robertson, J. Bernard, D. T. H. Blaton, Howard Butler, E. Butler, A. Marsden, and friends, the number present totalling 41.

Few speeches were delivered, the evening being mainly devoted to a musical programme. In proposing the health of Mr. W. Windus, Mr. W. Jones said that since Mr. Windus came to Bristol 50 years ago, the chemical industry had been transformed. Mr. Windus was first associated with the Netham Chemical Works, which was afterwards absorbed by the United Alkali Co. Mr. Windus, in reply, briefly reviewed the period of 55 years during which he had been associated with the industry and said that after the Franco-German war they had labour troubles similar to those of the present day. It took nine years before the high wages then paid were reduced to the normal level. He first came to Bristol in 1878 as manager of the Netham Works, at which the Deacon process was operated. After referring to the formation of the United Alkali Co. in 1892, Mr. Windus said that in 1914, the Germans had more chemists in Mannheim than we had in the whole of Britain. British brains, however, triumphed in the end. It was, perhaps, not generally known that 400 tons of poison gas was made at Avonmouth and that there was a casualty for every ton made. Production was forced to such an extent that towards the end the chemists had to look at the gauges through binoculars, owing to escapes. He hoped that more progress would be made in the next 50 years than in the past half-century.

LONDON SECTION

At the meeting held on March 5, Dr. T. M. Legge, C.B., H.M. Medical Inspector of Factories gave an interesting address on "Industrial Poisoning and the Works Chemist."

He asked for the assistance of the works chemist because he and they both desired the elimination of waste. In smelting works it was now possible to lay down a rule that if lead in the form of dust was present to a less extent than 5 milligrammes per 10 cubic metres of air, then lead poisoning would be rare. About 2 milligrammes of lead was the minimum daily dose that a worker could absorb and escape chronic lead poisoning. As an instance of what a works chemist could do, he cited the methods adopted by Mr. A. Klein at the works of the Brimsdown Lead Co., whose manufacture of lead bi-silicate had eliminated lead poisoning in the potteries. Mr. Klein had also been able to provide the rubber manufacturers with a lead compound which could be incorporated with rubber and avoid lead poisoning in that industry. Dr. Fox, of the Government Laboratory, had investigated poisoning by arseniuretted hydrogen, which came from a galvanised pail containing arsenic as an impurity. A system of exhaust ventilation would prevent many such cases. During the war there were cases of benzol poisoning in the rubber industry, and it was found that 20 parts of benzol per 10,000 parts of air was on the border of the danger line. Dr. Legge said if chemists, during their training, could get systematic information about the toxic properties of the materials they had to handle, it would be of great advantage. He also gave instances of poisoning by Aniline Black and dinitro-benzene derivatives, and in connexion with the doping of aeroplane parts with cellulose acetate.

In the discussion Mr. Potter explained how difficult it was for the works management to maintain a regular output, unless they took due precautions against danger from poisoning. He thought that chemists should understand the early symptoms of industrial poisoning, so as to investigate suspicious cases before the effects were serious. Mr. C. A. Klein called attention to Dr. Legge's investigation of lead poisoning in white lead works, the number of cases being reduced from 400 to 20 per annum in the course of very few years. Co-operation between the medical man and the works chemist would be of the greatest value. Dr. Paterson said the chemist could be effective in dealing with industrial poisoning in many works if he were encouraged by the management to work hand in hand with the medical staff. Dr. Coles dealt with precautions which should be taken to prevent poisoning by carbon monoxide. Mr. Finnemore alluded to the danger from dimethyl-sulphate. This and some other substances were carelessly handled because they were not known to be toxic.

MEETINGS OF OTHER SOCIETIES

CHEMICAL SOCIETY

An ordinary scientific meeting took place on March 15, presided over by Prof. Lowry and later by Prof. Thorpe.

The death was announced of Prof. van der Waals, who had been an honorary Fellow of the Society since 1898.

The President's address at the Annual Meeting, to be held on March 22, is to be on "Symbols and Formulæ."

Five papers were read at the meeting :—

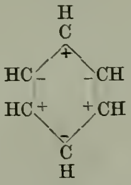
(1) "The oxime of mesoxamide (*iso*nitrosomalonamide) and some allied compounds. Part III. Ring formation in the tetra-substituted series," by E. H. Usherwood and M. A. Whiteley, who described reactions similar to the Thorpe condensation.

(2) "The preparation and stability of cuprous nitrate and other cuprous salts, in the presence of nitriles," by Mr. H. H. Morgan, who dealt with reactions found to occur when silver, in salts, is displaced by copper. Anhydrous substances were used, and the reactions were investigated in nitrile solution. Using aceto-nitrile, on evaporation of the solvent, colourless crystals such as the following were obtained :—$CuCl,CH_3CN$; $CuBr,CH_3CN$; $CuNO_3,4CH_3CN$. These were, however, only colourless in absence of air. Oxidation gave a green colour, a basic salt being formed. The author tried to prepare cuprous nitrate from the above double salt but obtained only cupric nitrate and copper. Using succinonitrile, a more stable double compound with cuprous nitrate was produced, corresponding to the formula $CuNO_3, 2C_2H_4(CN)_2$.

(3) The paper on "The interaction of hydrogen sulphide, thiocyanogen and thiocyanic acid with unsaturated compounds," by F. Challenger, A. L. Smith and F. J. Paton, was read by Dr. Challenger. He mentioned the fact that few instances were recorded in the literature of organic chemistry of interaction with hydrogen sulphide. Water brought about marked change in the products of the terpene series and the superficial similarity of hydrogen sulphide to water suggested that the former might also be very reactive. Few reactions were however found, so thiocyanogen, NCS-SCN, was tried. Addition compounds with unsaturated substances were recorded, and the analogy of the thiocyanate group with the halogens was brought out in these reactions. In reply to Prof. Pickard, Dr. Challenger said the substances were not specially unpleasant to work with ; it was rarely necessary to isolate thiocyanogen. Ethereal solutions were generally employed.

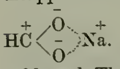
(4) Professor Robinson gave a paper dealing with reactions between formic acid and its derivatives and phloroglucinol which yielded xantho-pyrillium salts. Ketones added were found to take no part in the reaction.

The paper read by Professor T. M. Lowry, F.R.S., on the Polarity of Double Bonds was full of interest. It dealt with the two forms of electrical attraction which may bind together the atoms in a great variety of organic compounds. Of these the sharing of two electrons by two adjacent atoms is called covalency and is equivalent to a single bond. The attraction of a positive ion to a negative ion is called electrovalency and is equivalent sometimes to a single bond, sometimes to a less-defined attraction which, in the past, has been denoted by a pair of dotted lines and many other devices intended to indicate an attraction which is not confined to one single line. According to Lowry a double bond in organic chemistry usually behaves as if it is one covalency and one electrovalency; he writes aldehyde as $CH_3\cdot\overset{+}{C}H—\overset{-}{O}$ and ethylene as $H_2\overset{+}{C}—\overset{-}{C}H_2$; acetylene is $H\overset{-}{C}=\overset{+}{C}H$. Elements linked by electrovalencies are more active than those linked by covalencies. The author discussed the theory of partial valencies introduced by Thiele and the alternate polarities of Lapworth, Kermack and Robinson and the work of Thorpe on ethylidene maleic acid. Benzene, according to Lowry, has the formula:



and this was compared with Bragg's boat-shaped formula for benzene.

In some compounds a new element of symmetry is introduced because the distinction between a single and double bond usually disappears. Sodium formate becomes



$\overset{+}{HC}\left\langle\begin{matrix}\overset{-}{O}\\ -\\ O\end{matrix}\right\rangle\overset{+}{Na}$. The investigations of Goss, Ingold and Thorpe on ethylidene maleic esters were considered and Lowry's method applied to their results.

The introduction of electrovalencies into the structural formulæ of organic compounds provides a satisfactory interpretation of (1) unsaturation, (2) the activity of zinc methyl and the Grignard agent, (3) partial valencies, (4) conjugation, (5) alternate polarities, (6) crossed polarities in conjugated compounds, (7) the structure of benzene, (8) the laws of substitution in benzene, (9) crossed polarities in benzene, (10) the structure of naphthalene and anthracene, (11) the crystal structure of graphite, (12) the structure of carboxylic acids, (13) the structure of the glutaconic acids, (14) tautomeric or bipolar ions and, (16) the relation between tautomerism and co-ordination. The new formula for benzene reminds one of the centric bonds of Armstrong and von Baeyer and the author of the paper seems to be applying the modern discoveries to the elucidation of the problem which his predecessors were struggling to solve in the absence of the exact knowledge now available. The work of Kekulé and Berzelius in old times and of Thorpe, Sidgwick, Robinson, Ingold, Lapworth and many others in modern times may lead up to such an interpretation as Prof. Lowry is now engaged in developing. Had time permitted there would have been a valuable and critical discussion of the paper and there are many features which invite argument, in particular the chlorine derivatives of benzene. On the other hand the models prepared by Bragg enable modern speculators to check some of the important assumptions necessary to their theories and the time is ripe for a consideration of the best way of applying modern views of the structure of the atom to organic compounds as well as inorganic.

INSTITUTE OF METALS

The Annual General Meeting was held at the Institution of Mechanical Engineers on March 7 and 8, 1923, the President, Leonard Sumner, O.B.E., M.Sc., in the chair. An exceptionally large number of papers was presented and discussed. Dr. L. Aitchison, F.I.C., read a paper on "The mechanical properties of some magnesium alloys." Alloys containing 1 per cent. of cadmium, 3 and 13 per cent. of copper, and 6 and 11 per cent. of aluminium were found to be very weak in the cast state; the alloy containing 6 per cent. of aluminium was considerably improved by mechanical work (rolling or extruding). The results obtained were greatly inferior to those that can be obtained with the best alloys of aluminium. A paper entitled "Tests on work-hardened aluminium sheet," by Prof. H. C. H. Carpenter, F.R.S., and C. C. Smith, A.R.S.M., M.Sc., described the effects of annealing, at temperatures below 200° C., on cold-worked aluminium sheet. Work-hardness, as measured by the tensile strength, is not completely lost after two years' storing at 200° C., and it is only slightly removed at 100° C. At temperatures below 100° C. the retention of work-hardness is practically complete. A paper by Dr. A. W. Gray, on "Volume changes accompanying solution, chemical combination, and crystallisation in amalgams," was presented by Prof. Turner, in the author's absence: the work is mainly concerned with amalgams used for dental purposes, and the author discusses the "variable factors" connected with the making of these amalgams, and their effect on the subsequent volume changes. Maurice Cook, M.Sc., presented a paper on "The recrystallisation of cold-worked cadmium." The author finds that cold-worked cadmium recrystallises spontaneously at ordinary temperatures, but that, on annealing at higher temperatures (100° C. and upwards), rapid grain growth occurs. In the discussion on this paper it was pointed out that the author's results were readily explained as a consequence of the allotropic change at 60° C. in cadmium, which the author had ignored. Investigations into the constitution of the alloys of aluminium with copper and nickel formed the subject of two papers by C. R. Austin, M.Sc., and A. J. Murphy, M.Sc., and by Miss Bingham and Dr. J. L. Haughton, who investigated the alloys of this system containing less than 12 per cent. of copper and 10 per cent. of nickel, their research being, naturally, more complete over this limited range of composition than that of Austin and Murphy. Dr. W. Rosenhain, S. L. Archbutt, F.I.C., and S. A. E. Wells presented a paper on "The production and heat-treatment of castings in an aluminium alloy ('Y')." They describe the difficulties experienced in obtaining satisfactory castings; the chief causes of trouble were unsoundness and unsuitable structure. The density of the castings was found to give a very reliable indication of the soundness and approximate strength; success was attained by controlling the ratio of weight of mould to metal; the temperature of the mould; the maximum and pouring temperatures of the metal; and the rate of pouring. By heating the castings for 6 hours at 520° C. and quenching in boiling water, tensile strengths of over 20 tons per sq. in. were regularly obtained. Mr. R. Genders, B.Met., presented a note showing the manner in which the "extrusion defect" is formed in brass rods extruded from a multiple die. Another paper by the same author described a "new form of magnifier hammer" for use with the scleroscope, and made by using a hardened steel ball as the nose of the hammer, the ball being soldered in place with soft solder at the lowest possible temperature. Col. N. Belaiew presented a paper on "The inner structure of the crystal grain as revealed by meterorites and Widmanstätten Figures." Dr. D. Hanson and Miss M. L. V. Gayler, M.Sc., described some experiments on the heat-treatment and mechanical properties of alloys of aluminium with small percentages of copper. They showed how the difference in the solubility of the compound $CuAl_2$ in aluminium, at high and low temperatures, might be utilised to improve the mechanical properties of copper-aluminium alloys. Chill castings containing 4 to 5 per cent. of copper can be heat-treated in a simple manner to give strengths of over 17 tons per sq. in., and elongations of 20 per cent. Wrought alloys of the same composition possessed strengths up to 22 tons per sq. in. A paper by Harold Heape, on "The density and hardness of the cast alloys of copper with tin," compared the author's results with those of other workers; it appears that there is some relation between the density and hardness of these alloys, but chill castings are too unsound to permit reliable information being obtained.

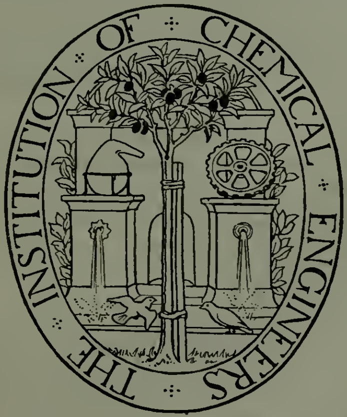
THE INSTITUTION OF CHEMICAL ENGINEERS

It is not often that a scientific society aspires to more than the most obvious emblem of its craft in choosing a badge or other distinguishing device. The Institution of Chemical Engineers, however, has combined plain speaking with happy symbolism in its design, which we here reproduce.

A young and sturdy tree—not yet without support—shows its first fruits between two fountains, bearing the emblems of Chemistry and Engineering. Their waters flow into a common pool, on the bank of which two doves are flirting happily.

It is not clear if there is any special significance in the choice of the tree, which is clearly of the "prunus" variety, but we have heard rumours of "plums of the profession" and it is certain that the apple which caused Man to fall is not appropriate here.

The design has been sketched by Mrs. Hinchley to embody the idea of the Institution as closely as possible and it has decorative charm and interest, which are quite exceptional.



THE INSTITUTION OF CHEMICAL ENGINEERS

The composition, the inspiration and the grace of this sketch have afforded us singular pleasure and we feel sure that the realisation of the artist's fancy will attract to the Institution a large number of members.

Mr. Cecil Thomas is working out the sketch in relief for the Seal and Medal of the Institution.

Sir Arthur Duckham is very kindly presenting the Seal to the Institution as a memento of his office as first President. The design, as a medal, will probably form an award for work of outstanding distinction in connexion with the objects of the Institution.

CORRESPONDENCE

THE TITLE "CHEMIST"

Sir,—The Retail Pharmacists' Union in their recent announcement with regard to the subject of the accurate dispensing of medicines have, I think it will be generally agreed, made a good statement on behalf of the profession of pharmacy.

I would, however, venture to place before your readers a matter, arising from the above, which is one of no small concern to those chemists who are engaged in the practice of *chemistry* as distinct from *pharmacy*—that is to say—who are concerned with the science of chemistry and its applications to the arts and manufactures, and have nothing to do with the dispensing of medicines.

The Retail Pharmacists' Union have headed their announcement with the words "The Chemist," and I would like to make, in the public Press, the suggestion which has so often been made in the scientific Press, that the time has come for the pharmacist to relinquish the use of the term "chemist" in favour of those who definitely practise chemistry.

The war was instrumental in directing the attention of the public more closely to the existence of the profession of chemistry, the profession on which the country found it necessary to rely for the production of explosives and materials of war generally, as well as for the means of protecting our troops against the methods of chemical warfare initiated by the enemy.

During the past half-century the science of chemistry has developed by leaps and bounds, and its practice as a profession has become more and more firmly established. In this country the science is now taught in 1000 or more public and secondary schools, and in nearly 300 technical schools, whilst our University Departments of Chemistry are renowned throughout the world.

The Institute of Chemistry, as the representative chartered professional body of chemists, numbers upwards of 4000 Fellows and Associates, whose qualification demands a four years' University course, or the equivalent, and the majority of whom are engaged in the many branches of industry on which the science has a bearing.

In other countries the strict equivalent of the word "chemist" signifies, as it should, one who professes chemistry, and not in any case the pharmacist, druggist or dispenser of medicines. How the misapplication of the word has arisen in this country is a matter which I need not here pursue. The enormous importance of chemistry is becoming daily more widely recognised, and it is highly desirable in order to avoid confusion that the name "chemist" should be confined to those who practise chemistry in the full sense of the word. It is bad enough when mental confusion is the unfortunate consequence of the poverty of a language, but in this instance the correct and distinctive words are ready to our hand.

I would like to express the hope which I have already expressed on a good many occasions, that our friends the pharmacists—notwithstanding the provision of the Pharmacy Act—will lose no opportunity of referring to their ancient and important calling by the word which more accurately defines and describes it. In addition, I would appeal to the Press, which is so important a factor in the enlightenment of the general public, to assist so far as they can by employing the terms "chemist" and "pharmacist" respectively in their obviously correct significations, so that those practising chemistry may be described as chemists, and those practising pharmacy as pharmacists.—Yours faithfully,

A. Chaston Chapman,
President of the Institute of Chemistry of Great Britain and Ireland
London, March 17, 1923

POLARITY IN ORGANIC COMPOUNDS

Dear Sir,—I hope that the time is not far distant when *Chemistry and Industry* will be read by every Fellow of the Chemical Society as a greatly improved version of the old Proceedings. In the meantime, may I be allowed to anticipate this future development by making use of your columns to reply to some of the points that were raised in the discussion following the reading of my paper on the "Polarity of Double Bonds" at the Chemical Society last night?

May I add that the President of the Faraday Society has authorised me to say that the Council of that Society has arranged to hold a conference at Cambridge on July 13 and 14 to discuss the "Electronic Theory of Valency," as applied both to inorganic and to organic chemistry, and that it is proposed to extend an invitation to members of other societies to attend and to take part in the discussion.—I am, Sir, etc., T. M. Lowry.

The University, Cambridge.
March 16, 1923.

Reply to Discussion on "The Polarity of Double Bonds"

1. Reactivity

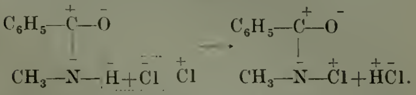
The fact that the reactivity of mixed double bonds varies from compound to compound may I think be interpreted in two ways. In the first place, it is clear that the change of free energy in the formation of the product must influence profoundly the velocity with which chemical change takes place. But in addition to this it is highly probable that (just as the velocity of bromination of acetone depends on the rate at which it can be enolised) the reactivity of a molecule like ethylene may depend on the rate at which the resting form of the molecule becomes reactive by the development of an electrovalency. In the same way the fact that propylene gives normal as well as iso-derivatives may depend on the fact that the resting form of the molecule may become reactive in either of two possible ways. In my paper I have preferred not to lay stress on this aspect of the question, because organic chemists are almost exclusively concerned with the molecule as it actually reacts, *i.e.*, with the appearance of the dog when standing up and barking, rather than when curled up and at rest.

2. Ionisation

The main characteristic of a metal is that it possesses a small surplus of electrons, *e.g.*, as compared with one of the inert gases. In most cases, therefore, it can only enter into chemical action as a kation, *i.e.*, by losing electrons, since the phenomenon of covalency is limited to those cases in which the shortage of electrons is so acute as to compel the atoms to share them. The only way in which the Grignard agent can be represented is, therefore, by some such formula as  $\overset{++}{Mg}\left\langle\begin{matrix}\overset{-}{CH_3}\\ \overset{-}{I}\end{matrix}\right.$; but this does not mean that the compound must give rise to conducting solutions, since the formula set out above corresponds with the "non-ionised" condition of a salt, such as sodium chloride. In order to produce an electrolyte, an ionising solvent must also be found, and this is likely to be a matter of some difficulty in the case of so peculiar a compound. Even if conductivity could be observed, the constituent ions would probably be magnesium monomethyl and iodine rather than a system containing free methyl ions. The idea of testing the electrical conductivity of compounds of this type in various solvents is, however, valuable, and suggests an important line of research. In the meantime it may be noted that Sir Joseph Thomson (*Phil. Mag.*, 1914 [6] 27, 757) has attempted to detect intramolecular ionisation in gases with the help of observations on specific inductive capacity and refractive index, and claims that he has detected ionisation in HCl, CH_3Cl, $CHCl_3$ (weak), H_2O, CH_3OH, C_2H_5OH, NH_3 and SO_2, whilst none could be found in H_2, O_2, N_2, Cl_2, He, CO, CO_2, CS_2, CH_4, CCl_4, C_6H_6 and N_2O.

3. The Mechanism of Chlorination

Most of the reagents that are used to bring about substitution in benzene contain two radicals of opposite types, namely, one radical that is to enter the ring, and a second radical which serves to remove the hydrogen in order to make room for the first radical. In chlorination both *radicals* consist of atoms of the same element, of which opposite functions are required, and to which opposite polarities have been assigned, *e.g.*, by G. N. Lewis and, over a long period of years, by W. A. Noyes. The mechanism of chlorination has not been established clearly in many cases, but it is known that, in the chlorination of acetanilide, the chlorine first attacks the side chain as indicated in the polar equation



$$\begin{matrix}C_6H_5-\overset{+}{C}-\overset{-}{O}\\ |\\ CH_3-\overset{-}{N}-\overset{-}{H}+\overset{-}{Cl}\;\overset{+}{Cl}\end{matrix}\;\longrightarrow\;\begin{matrix}C_6H_5-\overset{+}{C}-\overset{-}{O}\\ |\\ CH_3-\overset{-}{N}-\overset{+}{Cl}+\overset{+}{H}\overset{-}{Cl}.\end{matrix}$$

before swinging down into the *para*-position. The chlorine atom which enters the system is, therefore, positively charged, and behaves like the positively charged nitrogen of a nitro-group. When it has settled down in the benzene ring, the chlorine atom exchanges its electrovalency for a covalency and becomes neutral. It has, however, a latent negative polarity, since when removed from the ring, *e.g.*, by the action of caustic soda, it escapes as the anion of a molecule of salt and is replaced by the negatively charged oxygen of an—$\overset{-}{O}\overset{+}{Na}$ group. It, therefore, directs any further substitutents (including a second chlorine) to the *ortho-para*-positions, in just the same way as a phenol. Other cases of chlorination may be worked out in the same way, and a full consideration shows that there is nothing abnormal in the behaviour of the halogens, except their amphoteric character, which is already displayed in the two-fold function which they serve when used as reagents.

PERSONALIA

The Victoria University of Manchester has conferred the honorary degree of D.Sc. on Prof. Niels Bohr, of Copenhagen, and on Prof. F. Gowland Hopkins, professor of biochemistry in Cambridge University.

Dr. Lüppo-Cramer has been awarded the gold progress medal of the South German Photographic Association.

Monsieur Léon Guillet, the new president of the Société des Ingénieurs Civils, has succeeded the late Monsieur Adrien Bochet as Director of the Central School of Arts and Manufactures.

* * *

David Cochrane, the inventor of the open-feed water heater which bears his name, died on January 24.

The following deaths are announced from Germany :—Richard Fleitmann, General Director of the United German Nickel Works ; Prof. H. Fransen, of the Technical *Hochschule*, Karlsruhe, an active worker in the field of gas analysis, inorganic and bio-chemistry ; and Dr. Framm, director for 20 years of the Laboratory of the Union of German Portland Cement Manufacturers.

NEWS AND NOTES

JAPAN

Forecast of Formosa Sugar Crop, 1922-23

The second official forecast of the sugar crop of Formosa for the season 1922–23 estimates the total production at 6,423,684 piculs, made up of 5,212,503 piculs of centrifugals and 1,211,181 piculs of browns, representing a decrease compared with the previous season of 650,000 piculs. Conditions in the Formosa sugar industry are unfavourable, and the producing companies are effecting all possible economies with a view to reducing the cost of production to from 8 to 12 yen per picul.—(*Bd. of Trade J., Mar.* 8, 1923.)

SOUTH AFRICA

Industrial Progress

According to the industrial census for the year 1920–21, the value of articles produced and work done in factories and workshops (exclusive of railway and other Government workshops) in South Africa was £81,730,652, compared with £81,163,230 in 1919–20. The number of establishments increased from 6,581 to 6,688, and the number of employees from 145,998 to 146,675. Since the first industrial census was taken in 1915–16, the number of establishments has increased by 75 per cent., the value of land and buildings by 59 per cent., the value of machinery, etc., by 62 per cent., the value of raw material used by 160 per cent., the value of the total output by 143 per cent., and the value added to raw materials in manufacturing by 123 per cent.—(*Bd. of Trade J., Mar.* 8, 1923.)

Aluminium, 1919-1921

The Imperial Mineral Resources Bureau has issued a further pamphlet of its series on the Mineral Industry of the British Empire and Foreign Countries. From this pamphlet (pp. 31, price 1s.), devoted to the aluminium industry, including bauxite and cryolite, the following statistics of the world's production of bauxite and of aluminium (estimated) are extracted.

	Bauxite		Aluminium	
	1920	1921	1920	1921
	Long tons			
United Kingdom	11,020	2,269	8,000	5,000
British Guiana	22,084	19,694	—	—
India	3,932	6,652	—	—
Canada	—	—	10,000	3.000
Austria	356	2,596	3,000	3,000
France	183,693	83,577	10,000	6.000
Germany	13,200	—	15.000	14.000
Italy	12,928	48,311	1.218	730
Norway	—	—	7,000	5,000
Spain	531	181	—	—
Switzerland	—	—	10,000	6,000
United States	521,308	139,550	88,000	28,000

Cyrolite is apparently produced solely in Greenland. The exports in 1920 amounted to 13,704 tons, and in 1921 to 11,136 tons, directed chiefly to the United States and the United Kingdom.

The exports of aluminium and manufactures thereof from the various countries are summarised in a series of tables.

GENERAL

German Research Institute for Slag-cement

On December 19 last, the new Research Institute for Slag-cement, formed by the Verein Deutscher Eisenportlandzementwerke and the Verein Deutscher Hochofenzementwerke, was opened in Düsseldorf. The German slag-cement industry has now gained a position of equal importance with the Portland cement industry.

Beet-Sugar Industry in Italy

According to a report quoted in the *Giornale di Chimica Industriale ed Applicata* (Jan., 1923), the past beet-sugar campaign in Italy has been highly successful, the sugar content of the beets being appreciably higher than in previous years. The 39 factories in the country were all working, and the production will, it is estimated, reach 260,000 m.t. of refined sugar valued at 766 million lire. In the previous season, the production from 37 out of the 38 factories then existing, was 203,000 m.t. The output during the past season has only been exceeded in 1913-14, when the production exceeded 300,000 tons. The actual consumption in Italy is estimated at from 270,000 to 280,000 m.t., so that up to 20,000 m.t. of sugar will have to be imported.

An interesting experiment has been carried out by the Union of Sugar Manufacturers and by the Federation of Beet Growers to ascertain the possibility of selling beets by their sugar content. Laboratories have been set up at a cost of 250,000 lire at Rovigo, Bottriga and Mezzano, and the experimental results, which are to be published shortly, are stated to be extremely interesting. It is probable that next season beets will be sold on the basis of their sugar content as a result of the experiment.

The Pharmacology of Phenylenediamines

A recent issue of the *Journal of Industrial Hygiene* (Feb. 23) contains the conclusion of a long experimental study by Prof. P. J. Hanzlik on the pharmacology of certain phenylenediamines. The results indicate that the phenylenediamines are definitely toxic and a list is given of these compounds arranged in order of toxity. Their dimethyl-para- and diethyl-para-compounds are marked irritants to the skin. All the compounds stimulate the circulation and respiration, reduce the body temperature and lead to tremors, convulsions, coma and death. The asthma and respiratory symptoms of workers in the fur-dyeing industry in which para-phenylenediamine is used, are due to direct irritation and bronchial stimulation rather than to anaphylaxis. It is suggested that workmen should be protected against these compounds when used in industry, and that the use of para-phenylenediamine in hair dyes and cosmetics should be prohibited. Therapeutically, the phenylenediamines are of no importance and a scientific basis for the alleged benefits of metaphenylenediamine (lentin) as an anti-diarrheal and anti-dysenteric remedy is stated to be lacking.

REVIEWS

A Dictionary of Applied Chemistry. *By* Sir Edward Thorpe, C.B., F.R.S., *assisted by eminent contributors. Vol. IV. L.-Oxydisilin. Pp.* viii + 740. *Revised and enlarged edition. London: Longmans, Green, and Co.,* 1922. *Price* 60*s. net.*

This volume, a part of the new edition of "Thorpe," is a testimony alike to the diplomacy and tact of Sir Edward, and to the activity and courage of the publisher. It must have been no easy task for the Editor to handle the 120 odd contributors who are concerned in the writing of the various articles in the whole dictionary, and in these strenuous times it requires some optimism for the publishers to venture on such a work. The hard times alike affect the production and sale of a large work. Unfortunately, many manufacturers regard chemists as a luxury, an excrescence, an unprofitable "dead charge" on the works, which can be eliminated when times are bad. This, of course, just now prevents many a chemist from buying the work for his wife as a birthday present. Each edition, as might be anticipated, means the addition of another volume or two; and it is possible that in time the work will approach in magnitude the yet incomplete and cumbrous Muspratt's *Theoretische, praktische, und analytische Chemie in Anwendung auf Künste und Gewerbe.* It is to be hoped not, because the portability and handiness of the dictionary will then cease to be a merit.

The fourth volume, just published, covers subjects between L and Oxydisilin. The reviewer has read most of the longer articles, and has been impressed by their high order of merit. It would be invidious to make a special selection; and that would also illustrate more the temperament of the reviewer than the characteristics of the articles. The silicates are represented by a number of pithy notes on the minerals.

The need for inorganic chemists to come to an agreement on a system of nomenclature is very acute, and the arrangement of the names of compounds in the dictionary-form still further emphasises the attendant difficulties. For example, in the present volume, the last item, "Oxydisilin," would to some inorganic chemists appear like a card misplaced in a card-index.

As a kind of test, the reviewer wrote out a dozen names which occurred to him at random, but within the scope of this volume, and found all but one were treated satisfactorily within the limits imposed by the dictionary: he did not find "leukonin" mentioned. This seems a very good percentage of "hits." The earlier editions have established the utility of this work of reference, and there can be no doubt that the new edition will prove of even greater service.

J. W. Mellor

Manuel Pratique de la Fabrication des Encres. *By* L. Desmarest *and* S. Lehner. *Pp.* 372. *Paris: Gauthier-Villars et Cie.,* 1923. *Price* 12 *fr.*

Essentially this book is a combination of two books, the first portion on writing, copying, marking and miscellaneous inks, being in the main a French version of Lehner's well-known Austrian work, whilst the second portion, on printing inks, appears to be almost entirely French in its origin.

Part I is undoubtedly a valuable storehouse of recipes for the preparation of all kinds of ink, and the descriptive matter is clearly written and, on the whole, fairly accurate. In the chapters on the manufacture of writing and copying inks the writer is obviously speaking largely from his own experience, whereas the chapters on lithographic, marking and stamping inks appear to be mainly compilations, for they do not convey an impression of first-hand knowledge and are not quite up to date.

The section on writing inks is the work of the practical man rather than that of the chemist, for although an outline of the chemical theory underlying the formation of iron-gall inks is given, the methods recommended are based upon rough practical tests rather than upon the results of chemical examination. It is not unreasonable to infer that if the writer were in the habit of estimating the tannin in his raw materials, he would never have committed himself to the statement (p. 27) that good nut galls contain up to 27 per cent. of tannic acid. Even our despised English oak-apple can do better than that, whilst an average sample of Aleppo galls should yield well over 60 per cent. of gallotannin.

It is interesting to note that spent tan liquor and catechu are mentioned as being used in the manufacture of ink, which, so far as the reviewer is aware, is not the case in this country. On the other hand, there is no reference to myrobalans, which are commonly used in the preparation of certain English inks.

The section on marking inks gives most of the older formulæ, but there is no reference to the modern development of "one-solution" aniline inks. The use of concentrated sulphuric acid as a permanent marking ink for fabrics seems unlikely to become popular, even among those who by "much practice" have learned to use it without producing holes in the material (p. 211).

Chapters are also devoted to the methods of preparing inks for writing on different kinds of metals, on leather, ivory, glass, etc., and to sympathetic inks; and lithographic chalks and stamping inks are also dealt with in a useful manner.

Part II, which is concerned with the preparation and properties of printing inks, gives a good outline of the nature of the pigments used, the preparation of the varnish and the incorporation of the various ingredients. There are numerous useful formulæ for making printing inks for various purposes, and a valuable summary of Keghel's work on the manufacture of artificial lake pigments is included as a separate chapter (V). Here, again, the writer is obviously speaking from his own experience, but as in Part I, one misses any real correlation between the work of the chemist and that of the ink-mixer. For instance, no attempt is made to show the chemical reasons underlying the various faults to which printing inks are liable; in fact only two pages are given to the discussion of the qualities of a good preparation. The whole book would be of much greater value as a scientific guide to the manufacture of inks if it had been written upon the lines of Chapter V, to which reference has been made.

C. Ainsworth Mitchell

PARLIAMENTARY NEWS

HOUSE OF COMMONS

Exports of Coal

Replying to Mr. Gilbert, Lieut.-Col. Lane-Fox said that in February the export of coal from the United Kingdom totalled 5,902,630 tons, of which 1,000,097 tons was directed to Germany, compared with 4,014,344 and 359,889 tons, respectively, in February, 1922.—(Mar. 12.

British Empire Exhibition

Viscount Wolmer informed Mr. Darbishire that the British Empire Exhibition would open in April, 1924, and close about the end of October in that year. It was intended that the whole of the cost should be met out of receipts.—(Mar. 12.)

Imperial Institute

Mr. Ormsby-Gore stated, in reply to Sir J. Leigh, that the Grant-in-Aid of the Imperial Institute for the current year was £10,000. The contribution from Australia had ceased and that from India would cease after the current financial year. It was not known whether the contributions of the other Dominions would be continued or not. The report of the Committee now inquiring into the financial position of the Institute would not be available for some time.—(Mar. 12.)

Pitch

Answering Mr. M. Jones, Viscount Wolmer said that in 1922, the total production of pitch in the United Kingdom was 514,236 tons, of which 16,248 tons was produced in South Wales. Exports in the same year amounted to 428,317 tons. It would not be in the interests of industry to restrict the exports of pitch, nor could that be done without authority from Parliament.—(Mar. 13.)

Imports of Aluminium Hollow-ware and Glassware

In reply to Mr. Simpson, Viscount Wolmer said that during the six months ended December, 1922, imports of aluminium hollow-ware from Poland were valued at £36, and from Germany at £104,141. Imports of domestic and fancy glassware from Belgium during the same period were valued at £223,661 and from Germany at £89,856.—(Mar. 13.)

Dyestuffs (Import Regulation) Act

Mr. Baldwin, in answer to Lieut.-Col. Hilder, said he was not aware that German dyestuffs subject to the restrictions of the Dyestuffs Act, were being improperly introduced into this country from the Irish Free State, and he would be glad to hear of any cases where this was alleged to have occurred.—(Mar. 13.)

Home-grown Sugar Beet

In a written answer to Mr. Barnes, Sir R. Sanders said that the Kelham sugar factory had not operated since the excise duty on home-grown sugar was remitted. The whole of last season's beet-crop was worked at the Cantley sugar factory, 7,011 tons of white sugar being produced.—(Mar. 14.)

Reparation Duty

Mr. Baldwin, in answer to Mr. Graham-White, said that the net receipts under the provisions of the German Reparation (Recovery) Act during 1922 amounted to £6,847,000.—(Mar. 15.)

Chemical Factories in the Ruhr District

In a written answer, Lieut.-Col. Guiness informed Mr. Newbold that no facilities for producing poison-gas existed in the towns in Baden seized by the French Government.—(Mar. 15.)

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for March* 15)

TARIFF CUSTOMS EXCISE

Austria.—Goods subject to import licence include saccharin, dulcin, chocolate, opium; wares of rubber, leather, paper, asbestos; abrasives, china, wares of iron and common metals, salt, soda, calcium carbide, glue, varnish, soap, sugar, fats, oils, camphor, paraffin wax, vaseline, lubricating greases, nickel anodes, etc. A special export licence is required for preserved milk, charcoal, ammonium sulphate, anthracene, naphthalene, carbolic acid, fusel oil, and chlorosulphonic acid.

Belgium.—The import duties on sugar and matches have been amended.

British India.—Revised tariff valuations for paper have been issued.

Egypt.—Requirements for imports of alcohol are set out in the issue of March 15.

France.—An export prohibition has been applied to waste of tinned iron.

French Somaliland.—Regulations have been issued controlling the importation of and trade in poisons, including alkaloids and certain chemicals.

Italy.—Export licences are required for scrap of copper, brass and bronze.

Madagascar.—Modified consumption duties have been applied to soap, pottery, glassware, and iron and steel.

San Salvador.—A reduced duty of 40 centavos (gold) per kg. has been applied to pharmaceutical specialities with a base of pure paraffin oil.

South Africa.—A "dumping" duty equal to the difference between the home (Norwegian) and export prices, but not exceeding 15 per cent. *ad valorem*, has been applied to Norwegian cement.

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Canada ..	Disinfectants, disinfectant soap, insecticides, soap, wax ..	324
Egypt ..	Paper	362
,,	Oil, paint, varnish ..	10205/F.E./ C.C.2.
France ..	Raw sugar, palm kernels, groundnuts ..	351
Italy.. ..	Pig iron	353
Netherlands .	Silver and tin foil ..	18730/F.W./ M.C.2
Norway ..	Perfumery, soap ..	358
,, ..	Rubber flooring ..	359
Panama ..	Castor oil, soap, chemicals	366
Peru.. ..	Porcelain, crockery, glassware	367
South Africa	Insecticides, disinfectants	346
,,	Earthenware	347
Spain (Canary Islands) ..	China, glassware ..	360
Switzerland..	Soldering tin with resin centre.. ..	18866/F.W./ E.C.2
United States	Acetone	18776/F.W./ C.C.2
,,	Cresylic acid	18812/F.W./ C.C.2

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

A much stronger tone is evident in the market position to-day, prices as a consequence being very firm, and in many cases showing a tendency to advance. The almost complete cessation of supplies from Germany is largely the reason but at the same time the recently improved demand is expected to extend still further, with a general increase in trade. The Heavy Chemical section has shown particular activity of late, both at home and for export, especially in the latter direction. Altogether, the outlook is good, and only requires evidence of an early improvement in the comparatively parlous textile trade to justify a really optimistic forecast.

Acid Acetic, 40% tech..	£22 10s. per ton. Available supplies extremely limited, and price stronger.
Acid Hydrochloric ..	4s. to 5s. carboy.
Acid Nitric	£24 10s. per ton. Not in much demand.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw. is 70s., f.o.r. Makers' Works with slight variations up and down, due to local considerations.
Acid Sulphuric 94% arsenical	£6 10s. per ton.
Ammonia Alkali ..	£7 12s. 6d. to £8 per ton. Home trade maintained, with improved foreign business.
Arsenic (White).. ..	£72 to £75 per ton. Price unaltered, but not much doing at the figure.
Bisulphite of Lime ..	£7 per ton. Packages extra.
Bleaching Powder ..	£10 10s. per ton delivered. No change.
Calcium Chloride ..	£6 per ton delivered. Slightly better.
Copper Sulphate ..	£27 per ton. Somewhat firmer.
Potash Caustic, 88/90%	£31 to £32 per ton. Very firm, with prospects of shortage and probable increase in price.
Potassium Bichromate..	6½d. per lb. delivered.
Salammoniac	£32 per ton delivered.
Salt Cake	£4 10s. carriage paid. No change. Probably position will considerably improve with facilities for shipment in Spring.
Soda Caustic 76% ..	£20 to £21 per ton. Brisk demand particularly from the continent, where there appears to be a shortage of supplies.
Soda Crystals	£5 5s. carr. paid. Position well maintained.
Sod. Acetate, 97/98% ..	£25 per ton.
Sod. Bicarbonate ..	£10 10s. per ton. No change.

Sod. Bisulphite Powder, 60/62%	£19 10-ton lots; £19 10s. 5-ton lots; £20 2-ton lots; £20 10s. 1-ton lots. F.o.b. or f.o.r. London, 1-cwt. iron drums included.
Sod. Chlorate	3d. to 3½d. per lb., considerably firmer in price, demand not yet brisk.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide conc. ..	£15 per ton; much better tone, although still disappointing.
Sod. Sulphite, Pea Cryst.	£17 2-ton lots; £17 10s. 1-ton lots (1-cwt. wooden kegs included).

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£10 per ton d/d.
Grey	£20 per ton d/d.
Acetate of Lime Liquor	9d. per gall. 32° Tw.
Iron Liquor	1s. 6d. per gall. 32° Tw. 1s. 2d. per gall. 24° Tw.
Red Liquor	1s. 3d. per gall. 14/15° Tw.
Wood Creosote	2s. 6d. per gall. unrefined. Lower prices, however, are required in some quarters.
Wood Naphtha—	
Miscible	6s. 6d. per gall., 60% O.P.
Solvent	5s. per gall., 40% O.P.
Wood Tar	£5 per ton d/d.
Brown Sugar of Lead ..	£39 per ton d/d.

TAR PRODUCTS

Acid Carbolic, crystals..	1s. 7d.-1s. 8d. lb. Supplies very scarce, and price advancing. Demand well maintained.
Acid Carbolic, crude 60's	4s.-4s. 6d. Market advancing.
Acid Cresylic—97/99 ..	1s. 11d.-2s. 3d. per gall. Depending on quality. Rather more business passing.
Pale 95%	1s. 10d.-2s. 2d. per gall. According to quality. Not much demand.
Dark	1s. 9d. per gall. is the average price. Fair demand.
Anthracene Paste, 40%	4d. per unit per cwt. Price still nominal. No business doing.
Anthracene Oil—	
Strained	9½d. to 11d. Fair enquiries.
Unstrained	8¾d. per gall.
Benzole—	
Crude 65's	1s. 1d. per gall.
Standard Motor ..	1s. 6½d.-1s. 8d. per gall. Fair enquiry.
Pure	2s.-2s. 6d. Fair enquiry.
Toluole—90%	1s. 9d.-1s. 11d. Fair enquiries.
Pure	2s.-2s. 9d. Still steady.
Xylol	3s. 3d. per gall.
Creosote—	
Cresylic, 20/24% ..	11d.-1s. 1d. Fair demand. Price unchanged.
Middle Oil	8½d. to 10d. per gall. Regular and increasing demand.
Heavy	
Standard Specification	
Naphtha—	
Crude	9d.-9½d. per gall.
Solvent 90/160 ..	1s. 6d.-1s. 9d. per gall. Not many inquiries.
Solvent 90/190 ..	1s. 6d. to 1s. 7½d. per gall. Fair demand at steady prices.
Naphthalene, Crude—	
Drained Creosote Salts	£6-£9 per ton, according to quality. Supplies still scarce.
Whizzed or hot pressed	£10-£12 per ton. Prices firm for forward delivery.
Pitch, medium soft ..	£9-£10 per ton. Demand steady and plenty of inquiries.
Pyridine—90/140 ..	11s.-12s. 6d. per gall.
Heavy ..	8s.-9s. nominal.

INTERMEDIATES AND DYES

Acetic Anhydride ..	1s. 5d. per lb.
Acid H	5s. per lb. 100% basis d/d.
Acid Naphthionic ..	2s. 7½d. lb. 100% basis d/d.
Acid Neville and Winther	6s. per lb. 100% basis d/d.
Acid Sulphanilic ..	1s. 6d. lb. 100% basis d/d.
Aluminium Chloride anhydrous	1s. per lb. d/d.
Aniline Oil and Salts ..	9½d. per lb. naked at works.
Antimony Pentachloride	1s. 1d. per lb.
Benzidine Base	6s. 6d. per lb. 100% basis.
Benzyl Chloride.. ..	1s. 4½d. per lb. 100% basis.
Dinitrobenzene	11d. to 1s. lb. naked at works
Dinitrochlorbenzol ..	£95 per ton.
Dinitrophenol	£140 per ton.
Dinitrotoluene 48/50 ..	8d. to 9d. naked at works.
66/68 ..	1s. 2d.-1s. 3d. naked at works
Diphenylamine	3s. 2d. lb. d/d.
Dichloraniline	2s. 2d. lb. 100% basis.
Dichloraniline S Acid ..	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. per lb. d/d., packages extra.
Metanitraniline	5s. 6d. per lb. d/d.
Meta Phenylene Diamine	5s. 6d. per lb. d/d.
Meta Toluylene Diamine	5s. per lb. d/d.
Monochlorbenzol ..	£70 per ton.
a-Naphthol	2s. 9d. per lb.
β-Naphthol	1s. 1d. per lb. d/d.
a-Naphthylamine ..	1s. 6½d. per lb. d/d.
β-Naphthylamine ..	4s. per lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	7d. -8d. per lb.
Nitronaphthalene ..	1s. per lb. d/d.
Naphthionate Soda ..	2s. 8½d. per lb. 100% basis d/d.
o-Nitrochlorbenzole ..	2s. lb. 100% basis d/d.
p-Chlorphenol	4s. 6d. per lb.
p-Dichlorbenzol.. ..	£55 per ton.
p-Nitrophenol	1s. 9d. per lb. 100% basis.
p-Chloraniline	3s. per lb. 100% basis.
p-Nitro-*o*-amidophenol	4s. 6d. per lb. 100% basis.
p-Phenylene Diamine ..	12s. 6d. 100% basis d/d.
p-Toluidine	5s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Prices generally for pharmaceutical chemicals are very steady, although the market has been quiet during the past few days.

Acid Acetic 80% ..	£50 per ton. Very little available on spot, and no visible future supplies ex Continent.
Acid Acetyl Salicylic ..	3s. 1d. per lb. still quoted on a very firm market.
Acid Benzoic	2s. 3d. per lb.
Acid Citric	1s. 8½d. per lb., less 5%. Market steady.
Acid Gallic	3s. per lb. for 2-cwt. lots. 3s. 3d. per lb. for 56lb. lots.

Acid Pyrogallic, cryst.	5s. 9d. lb. Price advanced.
Acid Salicylic	Pulv. 2s. 3d. per lb., Cryst. 2s. 5d. per lb. Market very firm and considerable inquiry.
Acid Tartaric	1s. 2¾d., less 5%. As much as 1s. 3½d. per lb. has been asked for foreign makes. The increase in price is likely to be progressive, as reports from the Continent state that German deliveries are held up and Italian makers have raised their prices.
Amidol	9s.-10s. per lb.
Acetanilide	1s. 6d. per lb.
Ammon. Benzoate	3s. per lb.
Ammon. Carbonate B.P.	£37 10s. per ton nett.
Ammon. Sulphocyanide	2s. per lb.
Barbitone	15s.-16s. per lb. advanced, at which rate market is very firm.
Benzaldehyde	3s. per lb.
Benzonaphthol	3s. 9d. per lb. lower.
Bismuth Salts	Steady demand at unchanged prices.
Bromides	Considerably firmer. Higher prices are now quoted on the Continent.
Calcium Lactate	1s. 9d. per lb.
Chloral Hydrate	4s.-4s. 3d. per lb. Steady. Stocks small.
Formaldehyde, 40%	£88-£90 per ton.
Guaiacol Carbonate	8s. per lb. Very little demand exists.
Hexamine	4s. 3d. per lb., as quoted previously. This price is well maintained.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	3s. per lb.
Iron Ammon. Citrate	2s. 5d. per lb. for 1-cwt. lots.
Iron Perchloride	£20-£22 per ton.
Magnesium Carbonate—	
Light Commercial	£38 per ton.
Magnesium Oxide—	
Light Commercial	£85 per ton.
Heavy Commercial	£28 per ton.
Menthol	32s. for original cases. Smaller quantities 33s. lb.
Metol	12s. per lb.
Methyl Salicylate	2s. 3d.-2s. 4d. lb. Steady.
Methyl Sulphonal	12s. 6d.-13s. lb. Unchanged.
Mercurials	Very firm in view of the uncertain position of the metal.
Paraformaldehyde	3s. 3d.-4s. per lb.
Paraldehyde	1s. 6d. per lb.
Phenacetin	5s. 3d.-5s. 6d. per lb.
Phenazone	6s. 9d.-7s. per lb.
Phenolphthalein	4s. 9d. per lb. on a weaker market.
Potass. Bitartrate—99/100% (Cream of Tartar)	95s. per cwt. Market steady.
Potass. Ferricyanide	4s. per lb.
Potass. Iodide	15s. 8d. per lb. for cwt. lots. Good steady demand.
Potass. Metabisulphite	6d.-7d. per lb.
Potass. Permanagnate	9½d.-10d. per lb. Is now asked by some makers and still higher prices are anticipated.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz. Steady market.
Salol	2s. 3d.-2s. 6d. per lb. higher.
Silver Proteinate	10s. per lb.
Sod. Benzoate	2s.-2s. 3d. per lb.
Sodium Citrate—	
U.S.P. quality	2s. 2d.-2s. 3d. lb. } for quantity.
B.P.C. quality	2s. lb.
Sod. Hyposulphite—	
Photographic	£14 15s. for 5-ton lots.
Sod. Potass. Tartrate (Rochelle Salt)	82s.-85s. cwt. No change.
Sod. Salicylate	Slightly higher and very firm at 2s. 5d. per lb. for Powder, 2s. 6d. per lb. for Crystal.
Sod. Sulphite, anhydrous	£27 10s.-£28 10s. per ton, according to quantity; f.o.r. London, drums included.
Sulphonal	12s. 6d. per lb.
Tartar, Emetic	1s. 3d.-1s. 4d. per lb.
Thymol	19s. per lb. for good white crystal.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	12s. ,, ,,
Amyl Acetate	2s. 6d. ,, ,,
Amyl Butyrate	8s. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (melting point 21/22° C.)	4s. 3d. ,, ,,
Benzyl Acetate from chlorine-free Benzyl Alcohol)	3s. ,, ,,
Benzyl Alcohol free from chlorine	3s. ,, ,,
Benzaldehyde free from chlorine	3s. ,, ,,
Benzyl Benzoate, 19·5° C.	3s. ,, ,,
Cinnamic Aldehyde—	
98/100% Natural	14s. 9d. ,, ,,
Coumarin	13s. 9d. ,, ,,
Citronellol	22s. 6d. ,, ,,
Citral, 100%	9s. 6d. ,, ,,
Ethyl Cinnamate	18s. 6d. ,, ,,
Ethyl Phthalate	4s. 3d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa)	30s. ,, ,,
Geraniol	5s. 6d.-12s. 6d. per lb.
Heliotropine	7s. 6d. per lb.
Iso Eugenol	17s. ,, ,,
Linalol ex Bois de Rose	21s. ,, ,,
Linalyl Acetate	22s. 6d. ,, ,,
Methyl Benzoate	8s. 6d. ,, ,,
Musk Ketone	35s. ,, ,,
Musk Xylol	9s. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	17s. 6d. ,, ,,
Rhodinol	45s. ,, ,,
Terpineol	3s. 1d. ,, ,,
Vanillin	24s. ,, ,,

ESSENTIAL OILS

Almond Oil, Foreign, B.P.A.	13s. 6d.
Anise Oil, Red Ship brand	2s. 1d.
Cananga Oil, Java	9s.
Bergamot Oil	12s. 6d. spot, 13s. 6d. forwd.
Cinnamon Oil, Leaf	4½d. per oz.
assia Oil, 80/85%	8s. 3d.

Citronella Oil—	
Java, 85/90%	4s.
Ceylon	3s. 4½d.
Clove Oil	8s.-8s. 6d.
Eucalyptus Oil, 70/75%	1s. 9d.
Lavender Oil, Mont Blanc, 38/40%	12s. 6d.
Lemon Oil, Spot	3s. Higher prices are asked for forward delivery.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet, Spot	10s. 6d. Higher prices are asked for forward delivery.
Otto of Rose Oil—	
Anatolian	24s.
Bulgarian	26s.
Palma Rosa Oil	17s.
Peppermint Oil—	
English, Mitcham	80s.
Wayne County	13s.
Japanese	6s. 6d.

TRADE NOTES

The Photographic Fair

The large variety of exhibits at the Photographic Fair, now being held in London in the Holland Park Hall, affords convincing evidence of the progressive nature of this peculiarly British industry. All requirements—ranging from those of the most critical expert to those of the most helpless amateur—are catered for by the various photographic firms, and the quality of their products demonstrates how much the industry appreciates the value of the services of chemists and other scientific workers. Limitations of space alone prevent adequate mention of all the exhibitors, but, from the chemists' point of view, pride of place must be given to Johnson and Sons, Ltd. Amongst many photographic chemicals, this firm exhibits numerous developers, many of which, such as metol, hydroquinone and amidol, were not made in this country before the war, and a fine display of specimens of salts of gold, silver and platinum; mention should also be made of the universal single-solution developer, Azol, which replaces the German Rodinal, of a one-solution sepia-toner, and of dyes for tinting films, etc. Salts of the precious metals, so essential in photography, are also exhibited by Messrs. Johnson Matthey and Co., on whose stand specimens of barium platinocyanide, prepared for X-ray work, are to be seen. The help of science has never been neglected by Ilford, Ltd., a firm which exhibits a series of colour-sensitising dyes, the well-known "Desensitol" and various colour filters, including the new colourless "Q" filter containing acetaminoquinoline, which completely cuts off ultra-violet rays. Particularly noteworthy is the introduction by this firm of a new plate of the phenomenal speed of 700 H. & D., a claim well substantiated by the negatives made from it. An interesting series of prints illustrates the quality and utility of the panchromatic plates so long made by this firm. An ultra-speed plate of 650 H. & D., produced in four varieties, two of which are orthochromatic, is also made by the Imperial Dry Plate Co., whose exhibit includes a new roll-film, a series of light-filters, and plates and screens for X-ray work. Despite their speed, the ultra-rapid plates made by these two firms will withstand rough handling. Space is not available to comment on the variety of materials provided by other well-known firms or on the many aids to technical photography exhibited, but it is of interest to note the progress in the optical industry evidenced by the new lenses introduced by J. H. Dallmeyer, Ltd. (an anastigmat of 3 in. focal-length and the very large aperture of $f/2{\cdot}9$) and by Ross, Ltd. (a light, fixed-focus telephoto lens). Altogether the fair shows the steady advance of the photographic and related industries, and it is to be hoped that this will be appreciated both at home and abroad, as success in this direction is an important factor of the prosperity of our fine-chemical industry.

Department of Overseas Trade

This department has issued a useful handbook which explains the nature of its functions and some of the methods by which it carries them out. The department was founded in 1917 in response to a demand from business men for such an organisation, and that its work has been successful is shown by the strong representations made for its continuation when recently threatened with suppression. A tribute to its value is provided by the fact that its organisation has been copied by the Governments of some of our chief competitors. The handbook shows, briefly, how the department assists the British exporter, outlines the exports-credits scheme and states how information is distributed and how co-operation with the business community is maintained. Copies of the handbook can be obtained by United Kingdom merchants and manufacturers on application to the Department of Overseas Trade, 35, Old Queen Street, Westminster, London, S.W. 1.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, MARCH 29, 1923 No. 13

EDITORIAL

IN the issue of *Nature* for March 24 Messrs. C. J. Smithells and F. S. Goucher, of the Research Laboratories of the General Electric Co., Wembley, contribute a letter in which they state that, as the result of careful chemical and X-ray analysis of the black Maketu sand from which Dr. Scott had isolated the oxide of a new element, they are able to confirm Dr. Bohr's conclusion that no new element is present. Starting with 1000 g. of the sand, the authors obtained 1·7 g. of material free from silica and insoluble in sulphuric acid. As Dr. Scott found, this material was not brought into solution on fusion with sodium bisulphate, but on fusion with *potassium* bisulphate the residue went into solution completely, and was found by both chemical and X-ray analysis to consist of about equal parts of iron and aluminium. Prof. Bohr found an appreciable quantity of titanium in the residue, but the authors state that they only found a trace, and point out that as their residue was only 0·2 per cent. of the ore their extraction was probably more complete.

Whether the sand investigated by Messrs. Smithells and Goucher came from the same locality as Dr. Scott's sample is not stated, and further information seems desirable before it is assumed that his sand is identical with that from Maketu.

* * *

The Anniversary Dinner of the Chemical Society, held at the Hotel Cecil on March 22, was a conspicuous success, and gave great satisfaction to the large number of chemists of both sexes who were present. Our French visitors were able to meet a number of old friends and new acquaintances, who will retain a most agreeable recollection of the occasion. We were much gratified by the flattering remarks of the new President, Prof. Wynne, on the progress of this *Journal* since, with the co-operation of the Chemical Society, we have included both pure and applied chemistry in our pages. The reunion of chemists of every variety at the Hotel Cecil is a sign of a greater reunion of chemical activity, the manifestations of which are becoming now very frequent. In the early days of the science of chemistry the research student was busily engaged in attempting to solve the mysteries of Nature by heating together at a proper temperature and at the best phase of the moon, various oils, ores, powdered bricks, orpiment, litharge, horse-hair and other ingredients, and there seemed to be no reason why these novel methods of investigation should not speedily explain the present and the future, to say nothing of the past. It was somewhat unexpected that so immense a tract of knowledge should become visible as the result of these early experiments, and though astrology and mysticism were dropped out of the science it grew in bulk to an amazing extent, until a generation ago chemistry became too vast a subject for any one individual to cope with.

* * *

The early workers were explorers who found themselves confronted by a tangled mass of tropical jungle through which paths were cut with infinite labour, and in order to facilitate progress they formed groups of workers who specialised in the domains of inorganic chemistry, physical, organic, colloid and the many other varieties, leading somewhat independent existences, but each pursuing the rather tortuous path upon which he had commenced. But during the last few years it seems that these paths are converging and already the explorers in one locality hear the voices of their neighbours and occasionally get a glimpse of some exceptionally bold adventurer. They will shortly be meeting again on some common ground, and though much remains to be explored in various side issues, it is becoming obvious that we are approaching a period when there will be much greater community of ideas than has hitherto been possible. The physical conceptions which result from X-ray analysis are essential to the progress of modern organic chemistry: the spectroscopists and phtosynthesists are trying to explain how plants live and grow; the labours of Lewis and Langmuir will be applied to the investigation of indigo and the mathematical methods of Barlow and Bragg will be directed towards the preparation of photographic sensitisers.

* * *

It looks as if there will, in the near future, be a New Chemistry of the great principles which explain all the manifold branches of the science which have hitherto been somewhat segregated, and it is a fortunate circumstance that the Society of Chemical Industry has embarked on its new venture at a time when the increase of human knowledge shows signs of linking together again in a very rapid manner the interests of chemists of all sorts and conditions. We look forward to new books which will deal with chemistry as a whole in a manner entirely different from anything which has hitherto appeared, and can imagine only one diversion more fascinating than reading such books: that is, the writing of them.

* * *

If it be true that the underlying principles common to all branches of chemistry will turn out to be more numerous and important than now appears, we shall find a marked tendency during the next few years towards greater co-operation between the various chemical societies than has hitherto prevailed. The Annual Dinners of the Chemical Society will provide most pleasant opportunities for discussing some aspects of this problem, and others will no doubt receive attention from the Federal Council and the numerically smaller groups who frequent the Chemical Industry Club.

We see no signs that the public interest in chemistry is diminishing since the Armistice terminated that struggle, which compelled so many people in so many countries to engage in the manufacture of chemical compounds. On the contrary, we see signs that in education, in commerce, in financial circles, and in politics there has been an awakening of interest in the science and its applications, which will steadily grow so long as our leaders will take the trouble to make the public understand how chemistry contributes to our prosperity, our civilization and our happiness. This is to be achieved not merely through our daily and weekly Press, but also by the delivery of popular lectures and addresses which will be understood by those whose scientific knowledge is small. We wonder if one of our Societies could make such an experiment without unduly risking its reputation and prestige.

PATENT CLAIMS FOR PRODUCTS*

By ERNEST F. EHRHARDT, D.Sc., Ph.D.

To those who study patent law the development in various countries of the nature of the protection given to the patentee is a matter of great interest. In this country until lately there has always been room for difference of opinion as to whether valid Letters Patent could be granted for a new product, so as to enable the inventor of a new product to prevent any subsequent inventor, who devised a different process for making the same product, from carrying out his subsequent invention. There has been a swing of the pendulum going on for many decades, if not for centuries, with reference to this point. It may be thought that the 1919 Act settled the matter. This paper is an attempt to show some of the uncertainties it has introduced.

The expression used in the original Patent Act, the Statute of Monopolies, "any manner of new manufacture" was at first taken to include the article manufactured even if subsequently made by new processes. Later, the opposite view was held, and at any time during the last twenty years, one could have found leaders at the Patent Bar, some of whom would have given the opinion that there could not be a product claim in the above sense, whilst others expressed the opposite view.

The state of the law as applied to patents for coal-tar colours can well be seen by considering the judgment of Mr. Justice Wills in the case of Monnet *v.* Beck, R.P.C., Vol. 14, page 843. In the patent under discussion in that case, the third claim was: "As new products the colouring matters or dyes hereinbefore called Anisolines obtained substantially in the manner set forth."

Mr. Moulton argued that the claim should be read as if it were:—"As new products anything identical with the substances produced by my process, no matter by what process obtained."

The judge did not accept this construction of the claim, but confined it to colouring matters obtained by the process described, and then went on to say:—"I decide this question as to the third claim, not on the ground that there could not be a patent for all Anisolines as new things, but adopting the words of Cotton L.J. in Vorwerk *v.* Evans, 7 Patent Reports 265-271, that, having regard to the whole of this specification, it is not a claim to Anisolines only, but to those made in the way pointed out by the specification." This case shows that Mr. Moulton, as he then was, not merely submitted that there could be a claim for a chemical product which would cover that product, however obtained, but even argued that Monnet's third claim was such a claim in spite of the restriction "obtained substantially in the manner set forth." The judge decided that this restriction narrowed the claim so that it did not carry the invention beyond the process claims, but he particularly stated that he did not decide that there could not be a patent for all Anisolines as new things. This shows that in 1897 the point was quite an open one.

---

* Paper read at the Meeting of the Manchester Section, held on January 5, 1923.

I am not aware of any attempt by the Courts of the Legislature to settle the question until the new Patent Act of 1919 came into force. Section 11 of that Act was apparently intended to settle this point; there was inserted in the principal Act, a new Section 38*a*, which opens as follows:—"In the case of inventions relating to substances prepared or produced by chemical processes or intended for food or medicine, the specification shall not include claims for the substance itself, except when prepared or produced by the special methods or processes of manufacture described and claimed or by their obvious chemical equivalents." The results of this alteration of the law have been curious, and some of them, I think, were not intended by those who suggested the amendment of the law. In the first place, by this alteration of the law the doctrine of Heath *v.* Unwin was definitely made applicable to the product claims of chemical patents. It will be remembered that, in the case of Heath *v.* Unwin, it was decided that the change of a process by substituting for "carburet of manganese," a mixture of "oxide of manganese and tar" did not constitute an infringement of the "carburet of manganese" process patent because it could not have been foretold with certainty, at the date of the specification, that the tar and manganese oxide would have acted in the same way as the "carburet of manganese."

The most recent case in which this doctrine has been applied to a dyestuff patent is the Sulphur Black case—A.-G. für Anilin Fabrikation *v.* Levinstein, Ltd. In that case the patentee claimed the manufacture of a sulphur black "by boiling dinitrophenol with an aqueous solution of sulphur and a sulphide of an alkaline metal." The defendants, instead of using dinitrophenol itself as claimed, used sodium dinitrophenolate—that is, the corresponding sodium salt of the free acid claimed. Applying the doctrine of Heath *v.* Unwin, the Court of Appeal said:—"We think the real question is whether in 1900, at the date of the plaintiff's patent, it was known to persons reasonably instructed in the industry, that a claim for the process of boiling dinitrophenol, with an aqueous solution of sulphur and a sulphide of an alkali metal, would necessarily cover one from which dinitrophenol is excluded and in which sodium dinitrophenolate is substituted." They decided that this was not the case, and that there was no infringement.

This doctrine of Heath *v.* Unwin now becomes applicable to product claims because a claim to a product has to be restricted to the special process by which the new product is obtained:—"The specification shall not include claims for the substance itself except when prepared or produced by the special methods or process of manufacture described and claimed or by their obvious chemical equivalents."

If we were to apply this section to one of the most striking recent inventions of a new chemical dyestuff, we could perhaps best take for that purpose the invention of Jade Green by the chemists of Scottish Dyes, Ltd. That is beyond doubt a new product. If anyone makes a change in the process of producing it which satisfies the conditions of Heath *v.* Unwin he will be in a position to manufacture and sell his Jade Green without regard to the patent of Scottish Dyes, Ltd.

This result strikes me as curious, although it must be taken to have been intended by those who made this amendment in the law; but when we come to other results of the amendment now embodied in decisions of the Patent Office and the Law Officer of the Crown (R.P.C., Vol. 38-39, pp. 292 and 264), the effects can only be adequately described as "curiouser and curiouser"

It will be noticed that in the new section substances prepared by chemical processes are coupled together with substances intended for food or medicine, and the same alteration in the law is made with reference to specifications relating to inventions of these three classes—food, medicine, products of chemical processes—and so a decision on a food patent interprets the law as to product obtained by chemical processes.

Recently a patent was put in which included the following claim:—"A step in the process of making bread, as claimed in Claim 1, which consists in immersing flour for some time in an atmosphere of strong chlorine gas so that the flour absorbs and is acted upon by the gas, and incorporating with this chlorine-treated flour acid ammonium sulphate, so that when the flour thus treated is made into dough and baked, the results set out in the specification are secured." This claim has been disallowed under the new section to which I have repeatedly referred, and the rejection has been upheld on appeal to the Solicitor-General. You will note that the claim is a process claim; it covers a step in the process of making bread, which consists in immersing the flour in chlorine gas so that the flour absorbs and is acted upon by the gas, incorporating this treated flour with ammonium sulphate, making dough and baking to bread, and yet this *process* claim is rejected under the new section, which on the face of it refers only to *product* claims.

The reasons given for this decision are very subtle; first of all, there is the argument that, while this claim is in form a process claim, it is in effect a product claim, because *the only way* of making this composition is by mixing the ingredients together. If only one way is known of making a product, a patent for that way of making the product gives the patentee the monopoly of the product; a claim for the process has all the effect of a product claim because no alternative way of making the product is known. Consequently, so long as a process claim covers the only way of making its product it is in effect a product claim, and, in accordance with this decision of the Solicitor-General, it must be considered to fall under this Section 38*a*.

The second step of the reasoning by which this process claim has been rejected is equally subtle; it turns on the *wording* of the section which provides that the specifications for the bodies in question shall not include claims for the substance itself, except when prepared or produced by the *special* methods or process of manufacture described and claimed. It was held that the process described was not "special." What is meant by the word "*special*"? It was contended on behalf of the patentee that the word meant the particular process claimed, but the retort was that then it was superfluous and that the section might have read that the specification shall not include claims for the substance itself except when prepared or produced by the methods or processes of manufacture described and claimed. This is, in my opinion, the plain and obvious meaning of the section. That argument was, however, not accepted The Legislature must have meant something by inserting the word "special," and the question arises in the case of any process claim which is in effect a product claim, *is it special?* If it is not special it is to be rejected. As to what is or what is not special I can give no guidance, because the claim set out above was decided not to be "special."

I can understand anyone who eats bread exclaiming, upon reading this process, "What a nasty thing to do—to treat the flour from which bread is to be made with a poison gas and then mix it with ammonium sulphate before turning it into dough and bread," and one is inclined to think that the officials of the Patent Office and the Solicitor-General were keen to find a way of preventing an inventor of a nasty process like this being rewarded with a Letters Patent; but when we consider the effect of this decision on patent applications for dyestuffs there is reason to anticipate serious difficulties.

If a man prepares a new azo dye by diazotising a new amino body in the usual way, and combining it in the usual way with a well-known component, will he be allowed to claim the process for the manufacture of his new colour? His claim to the process will in effect be a product claim, for as a rule azo dyes can only be made by the process referred to. The section will apply to a patent of the nature I have mentioned; will the process of making azo dyes be regarded as special?

It may well be argued by an opponent of the patent that, since there is only one method of making the particular azo body, the claim is a product claim. Since it is a product claim, it is to be disallowed unless the method of preparation described is a "special" method within the meaning of Section 38*a*. As to the meaning of "special," the only reported instance of a decision on the point is one in which a clearly-described series of chemical operations was held not to be a "special" method. If impregnation of the raw material with chlorine, and heating with the acid sulphate of ammonium is not a "special" method, why should diazotising be "special" when scores of bodies are diazotised daily in the usual course of chemical manufacture.

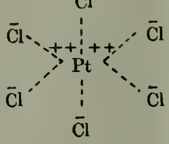
The decision in the flour case is clearly bad, but it is to be feared that inventors of chemical processes for making new substances will be liable to have trouble with their applications until another case can be taken up to some other Law Officer, when some way of reversing the decision for all practical purposes will be found.

SOME FACTORS INFLUENCING CO-ORDINATION

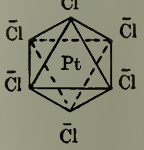
BY PROF T. MARTIN LOWRY, F.R.S.

1. *Close-packing of Ions*

(*a*) The fundamental factor in co-ordination is a close-packing of ions. This is similar, both in origin and in character, to that which we now know, as a result of X-ray analysis, to prevail in crystals. Thus, when platinic chloride is mixed in aqueous solution with an excess of potassium chloride, the quadruply-charged platinic ion, $\overset{++++}{Pt}$, attracts to itself a shell of six chlorine ions, as in the formula I. below. In this formula the electrostatic attractions, or electrovalencies, between the ions are represented by dotted lines, in the manner commonly employed to represent "partial valencies"; but the distinction which is sometimes made between the four "primary valencies" of the $PtCl_4$ molecule, and the two supplementary valencies of the $PtCl^{--}$ ion is not, and indeed cannot be, maintained.



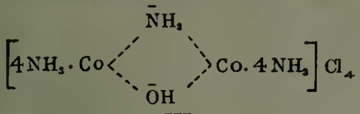
I.



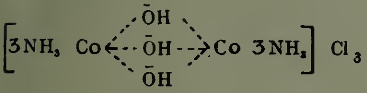
II.

The orientation of these six ions is identical with that of the six chlorine ions which are distributed round each ion of sodium in a crystal of rock salt, and is shown clearly in formula II. This octahedral arrangement of the groups in co-ordinated compounds of the type [MeR_6] has been established by proofs of precisely the same type as those used by van't Hoff in establishing the tetrahedral symmetry of methane, or by Kekulé in establishing the hexagonal formula for benzene, and rests upon an equally firm experimental basis.

(*b*) The idea that the principal forces in co-ordination are of the same character as those which determine the formation of crystals finds support in the fact that negative ions can link together ions of metal, just as metals can co-ordinate a number of negative ions. The sharing of negative ions by two adjacent metallic atoms is, however, limited to three, since this is the maximum number of apices that can be brought together in two adjacent octahedra. Thus Werner has prepared octammine-aminol-dicobaltic salts of the type III. and hexammine-triol-dicobaltic salts of the type IV.

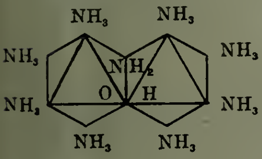


III

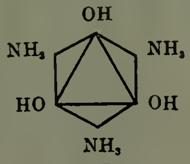


IV

The former compound may be represented by the symbol V; in the latter compound each half of the molecule is represented by the symbol VI., but the top face of the octahedron is shared with a second octahedron resting symmetrically upon it.



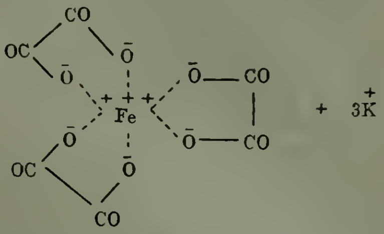
V



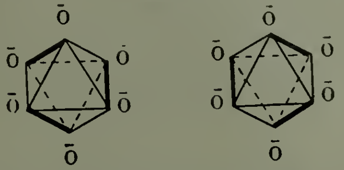
VI

A number of compounds containing *three* atoms of cobalt linked together in this way have also been prepared by Werner, and these may be expected to show complex isomerism, corresponding with that observed in derivatives of polycyclic hydrocarbons such as anthracene.

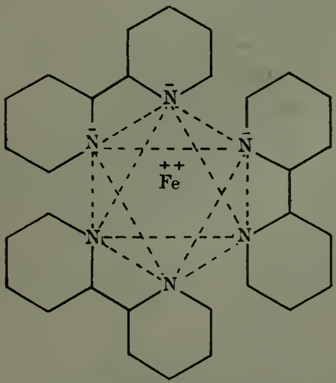
(*c*) In the case of bivalent anions, such as those of the oxalates, negatively charged oxygen atoms take the place of the negatively charged univalent chlorine ions of the platinichlorides; but the bridges between the oxygens reduce the symmetry of the complex to a point at which optical activity may be developed even in such simple compounds as the ferrioxalates —*e.g.*, $K_3[Fe.3C_2O_4]$. The ions of this salt may be formulated as



The enantiomorphism of the series of oxalates of the type M_3 [$Me.3C_2O_4$] can be seen more clearly by marking the bridges between the oxygen atoms by heavy lines instead of inserting the complete –CO–CO– groups, thus :



(*d*) Another case of the same type as the oxalates, but with a basic radical as the co-ordinated complex, is that of the additive compound of ferrous chloride with three molecules of α-dipyridyl, $FeCl_2,3C_{10}H_8N_2$, or [Fe.3Dip]Cl_2. In this compound the bivalent atom of iron is surrounded octahedrally by six nitrogen atoms, to each of which the theory of "mixed double bonds" would assign a negative charge. This compound has also been prepared in optically active forms, one of which only is formulated below :—



The hexagonal ring-systems shown in the formula are not parallel to the plane of the paper,

A

but are inclined to it like the blades of a propeller revolving about the central three-fold axis of the figure.

2. *Completion of Shells of Electrons.*

(*a*) A second factor in determining the stability of co-ordinated compounds is the completion of shells of electrons. Langmuir has attributed the high valency of the metals in the three carbonyls

$$Mo(CO)_6,\quad Fe(CO)_5,\quad Ni(CO)_4$$

to the fact that molybdenum requires 12, iron requires 10, and nickel requires 8 electrons to complete the outer shell. In the case of co-ordinated compounds, the central atom of metal is present as an ion—*i.e.*, it has lost some of its electrons, and therefore requires a larger number of electrons in order to complete its outer shell. It is therefore probably much more than a mere coincidence that, when allowance is made for this difference, the number of co-ordinated groups so often agrees with the number of molecules of carbon monoxide required under Langmuir's scheme to complete the shell of electrons. Thus the platinum atom, with atomic number 78, contains 2+8+8+18+18+24 electrons in the successive shells. The platinic ion, $\overset{++++}{Pt}$, therefore contains 20 electrons in the outer shell, and requires 12 more to complete the shell of 32. By drawing into this shell one pair of electrons in each of six chlorine atoms, the outer shell can be completed. In the same way cobalt, with atomic number 27, contains in successive shells 2+8+8+9 electrons. The cobaltic ion $\overset{+++}{Co}$ therefore contains 6 electrons in the outer shell and requires 12 more to complete it. It finds these by drawing into its orbit six atoms of ammonia, as in the hexammine $[Co.6NH_3]Cl_3$, where the ammonia is held so strongly that it cannot be displaced even by sulphuric acid.

(*b*) This factor may be invoked in order to account for the stability of the six-fold co-ordination compounds of $\overset{++++}{Pt}$, $\overset{+++}{Co}$, $\overset{+++}{Rh}$, $\overset{+++}{Ir}$, $\overset{++}{Fe}$, in all of which the outer shell of electrons can be completed by the attachment of six co-ordinated groups. It also accounts for the vigour with which potassium cobalto-cyanide, $K_4CoC_6N_6$, passes into the cobalti-cyanide, $K_3CoC_6N_6$, an action which is sufficiently violent to liberate hydrogen from acids and to convert oxygen into hydrogen peroxide.

$$2K_4CoC_6N_6+2HCl=2K_3CoC_6N_6+2KCl+H_2$$
$$2K_4CoC_6N_6+2HCl+O_2=2K_3CoC_6N_6+2KCl+H_2O_2$$

All this fuss arises from the fact that the cobaltocyanide ion contains, on the basis of the electronic theory of co-ordination, one surplus electron over and above those required to complete the outer shell! The surplus atom of potassium in potassium cobaltocyanide therefore behaves almost as if it were in the metallic state, and is almost ready to decompose water, like metallic potassium, in the effort to get rid of an unwanted electron.

The same factor may, however, also be invoked to account for the fact that this order of stability is reversed in the corresponding compounds of iron. Here the co-ordinating force of the triply charged ferric ion, $\overset{+++}{Fe}$, would normally be much greater than that of the doubly charged ferrous ion, $\overset{++}{Fe}$. The greater stability of the ferrocyanides may be attributed to the fact that the ferricyanides are one electron short of the number required to complete the outer shell, and are therefore ready to acquire one by passing over into ferrocyanides. This shortage of electrons is, however, tolerated much more readily than a surplus, as is indeed indicated by the fact that a shortage of 3, 2 and 1 electrons respectively is found in the co-ordinated compounds of $\overset{+++}{Cr}$, $\overset{++}{Pt}$ and $\overset{+++}{Fe}$, typified by the formulæ

$$K_3[Cr.6CN],\quad K_2[Pt.4CN]\quad \text{and}\quad K_3[Fe.6CN].$$

(*c*) According to the views set out above compounds with a co-ordination number of four, compare $Ni(CO)_4$, should be specially frequent in *univalent* elements containing *one* electron more than nickel and its homologues, *bivalent* elements with *two* more, etc.; or alternatively in elements occupying similar positions relatively to the inert gases He and Ne, which also require eight electrons to reconvert them into the inert gases Ne and A. This conception finds support in the fourfold co-ordination compounds of bivalent beryllium as well as in the existence of compounds such as $KAlCl_4$, $K_2ZnC_4N_4$, K_2HgI_4, etc. This type of co-ordination is, however usually much less stable, and is of far smaller importance, than the sixfold co-ordination discussed above.

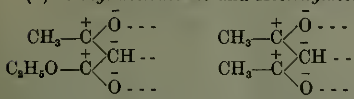
3. *Tautomeric Ions*

(*a*) It is remarkable in how many cases tautomeric ions give rise to co-ordinated compounds. This term is here applied to ions which, although often represented by different formulæ, are (in the sense of Laar's original definition) "not isomeric but identical." A common feature of all these ions is that hydrogen, or an alkyl radical, can be attached to the ion *at two different points*. One of the most important results that follow from the theory of "mixed double bonds," which I described at a meeting of the Chemical Society in October, 1922, is that the two tautomeric forms of these ions become identical in appearance as well as in fact. This may be illustrated in the case of four typical ions as follows:—

(i) *Hydrogen cyanate* and *Hydrogen thiocyanate*

$$\cdots\overset{-}{O}-\overset{+}{C}=\overset{-}{N}\cdots\qquad\qquad \cdots\overset{-}{S}-\overset{+}{C}=\overset{-}{N}\cdots$$

(ii) *Ethyl acetoacetate* and *Acetonylacetone*



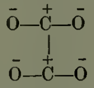
In these formulæ the alternative points of attachment are represented by dotted lines; and these do in fact represent fields of force having the character of the "partial valencies" which this sign is often used to denote. The existence of two or more *similar* points at which a hydrogen atom or a radical can be attached, where the older formulæ indicated a difference, is also seen in the corresponding formulæ for the ions of :—

(iii) *Nitrous acid* $\overset{-}{O}—\overset{+}{N}—\overset{-}{O}$

(iv) *Formic acid and Acetic acid*

$\overset{-}{O}—\overset{+}{C}H—\overset{-}{O}$ and $\overset{-}{O}—\overset{+}{C}Me—\overset{-}{O}$

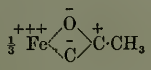
(v) *Oxalic acid*



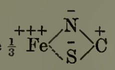
$$\begin{array}{c}\overset{-}{O}—\overset{+}{C}—\overset{-}{O}\\ |\\ \overset{-}{O}—\overset{+}{C}—\overset{-}{O}\end{array}$$

(*b*) The use of these formulæ introduces a new element of order into the study of co-ordination-compounds, as may be illustrated in the following cases, where in each instance the symbols to the right of the metal are repeated three times in the complete formula of the compound :—

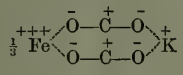
(i) Ferric acetate



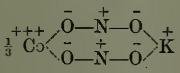
(ii) Ferric thiocyanate



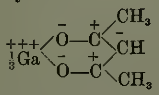
(iii) Potassium ferrioxalate



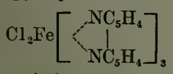
(iv) Potassium cobaltinitrite



(v) Gallium acetonylacetone



Ferric acetate and ferric sulphocyanide are probably unstable co-ordinated compounds, since they possess the red colour which Werner uses as evidence of the co-ordinated character of ferrous-tri-dipyridyl chloride :—



and of the iron in hæmoglobin. It will be noted that a place has been assigned to the potassium ion in the formulæ of the complex double oxalates and nitrites. It is probably legitimate to think of the univalent metal as "co-ordinated" in this way with two negatively charged oxygen atoms, either when *in the undissociated state* or when *in a crystal;* but this can only be regarded as the very weakest type of co-ordination.

4. *Summary*

(*a*) Co-ordination is the result of an attraction between ions, which is similar, both in origin and in its geometrical effects, to the forces which bind together the ions in crystals, such as rock-salt.

(*b*) In the compounds of $\overset{++}{Fe}$, $\overset{+++}{Co}$, $\overset{+++}{Rh}$, $\overset{+++}{Ir}$, $\overset{++++}{Pd}$ and $\overset{++++}{Pt}$, six co-ordinated groups are just sufficient in number to complete the outer shell of electrons of the metal, if each group shares one pair of electrons with the metal. The ammines, such as $[Ir.6NH_3]Cl_3$ and $[Pt.6NH_3]Cl_4$ and the metallic carbonyls, such as $Mo(CO)_6$, $Fe(CO)_5$ and $Ni(CO)_4$, appear to owe their formation and stability to this sharing of electrons. Whilst a deficiency of 1, 2 or 3 electrons can be tolerated readily, the surplus electron of potassium cobaltocyanide is expelled with great violence from the co-ordinated complex, giving rise to the extremely stable cobalticyanide.

(*c*) Co-ordination usually involves the attachment to a metal of more radicals than it can carry on the old theory of valency. The theory of "mixed double bonds" allows this to be expressed by means of symmetrical formulæ in compounds, such as ferric acetate.

(*d*) Tautomeric ions, which can be written in two ways since they possess two possible points of attachment for a hydrogen nucleus or an alkyl group, often give co-ordinated complexes, in which a multivalent ion is attracted to both points simultaneously.

NOTES FROM HEATHFIELD—III

By the Rector, Rev. B. V. WHITE, M.A.

Dear Mr. Editor,—The avocations of a country clergyman tend rather towards those departments of knowledge which can be developed by the perusal of books—especially the older and simpler sort—than those which demand costly pieces of apparatus and the study of what are now distinguished by the name of "transactions." I fear that I shall never attain to a deep understanding of most of the branches of chemistry, but I hope I may spend many an agreeable hour with the writers of bygone days—Glanvill, Thomson, Boyle, Faraday, Franklin and Bishop Watson; from the last, indeed, I claim to be a remote descendant.

It gave me quite an exaltation of my spirits to read the proposals for a convocation of chemists in Cambridge next June, and I think it highly probable that I shall myself be present. I was hardly more than eleven or twelve years old when I was taken there by my parents, and I well remember my first impressions of the colleges and the King's Parade. The charm and peacefulness of the town was a great change from the dirt and noise of Bradford, where I was born and spent my early days. It was on this occasion that I first met my future spouse, then a mere child. As Virgil puts it :—

" Saepibus in nostris parvam te roscida mala
dux ego vester eram—vidi cum matre legentem ;
alter ab undecimo tum me jam acceperat annus ;
jam fragiles poteram ab terra contingere ramos ;
ut vidi, ut perii."

As some of your readers have not that knowledge of Latin, which I am glad to find Professor Baly has, I append a translation of these charming lines : " It was in our orchard I saw you gathering apples with the dew on them. I myself was your guide, in company with my mother—another year had just bidden me leave my eleventh, and I could barely reach from the ground to the tender branches. I watched you, and fell a prey."

Professor Baly has been most obliging, and his communication to you has been, as it were, an arc-lamp compared with my poor little candle. And it comes into my mind that, in my father's time, a green colour obtained from nettles, was used for colouring sweets, and candles, and some other objects. Now, there is one very surprising observation about green candles which, if confirmed, may be of great interest.

Sir David Brewster records it in one of his " Letters on Natural Magic," addressed to Sir Walter Scott in the year 1834 (p. 319) : " A singular species of invisible combustion, or of combustion without flame, has been frequently noticed. I have observed this phenomenon in the small green wax tapers in common use. When the flame is blown out, the wick will continue red hot for many hours ; and if the taper were regularly and carefully uncoiled, and the room kept free from currents of air, the wick would burn on in this way till the whole of the taper is consumed. The same effects are not produced when the colour of the wax is red. In this experiment the wick, after the flame is blown out, has sufficient heat to convert the wax into vapour, and this vapour, being consumed without flame, keeps the wick at its red heat. A very disagreeable vapour is produced during the imperfect combustion of wax." Sir David Brewster, like Sir Humphry Davy and Michael Faraday, was the recipient of the three great medals of the Royal Society —the Copley, the Rumford, and the Royal ; so that we cannot doubt the accuracy of his statement that the green taper burns continuously whilst the red one does not, although he offers no explanation. Is it possible that photo-catalysis occurs as between the green chlorophyll and the formaldehyde produced by the incomplete combustion of the wax ? Now, whether " isorropesis " or what other action accounts for this I know not.

It is the incredible observations both in theology and science which are the most important and interesting, as indeed Sir Oliver Lodge has recently pointed out in a lecture published in *Nature*. I must leave the discussion of green candles to those who are better informed than I am, and make use of this occasion to offer to Professor Baly my most hearty thanks for his admirable elucidation. As for the sceptical friends I mentioned in my previous letter, they inform me that they propose to repeat Professor Heilbron's experiments, using synthetic ammonia, which is now being manufactured in the vicinity of the district in which they reside.

In reply to your correspondent who signs himself " Sales Manager," the poem, " The Progress of Man " is contained in the poetry of the anti-Jacobin, of which my edition was published in 1800. The author of it, I find, was George Canning, and the following extracts illustrate the nature of it :—

" The feather'd race with pinions skim the air—
Not so the mackerel and still less the bear :
This roams the wood, carniv'rous for his prey !
That with soft roe, pursues his watery way.

. . . . .

Ah ! who has seen the mailed lobster rise,
Clap her broad wings, and soaring claim the skies ?

. . . . .

The same with plants—potatoes 'tatoes breed—*
Uncostly cabbage springs from cabbage seed ;
Lettuce to lettuce, leeks to leeks succeed ;
Nor e'er did cooling cucumbers presume
To flow'r like myrtle, or like violets bloom.
Man, only—rash, refined, presumptuous Man—
Starts from his rank, and mars creation's plan.

* Elision for the sake of verse, not meant to imply that the root degenerates."

I have often pondered over the way in which light may be influenced by the cells in the tissues of the plant. An acquaintance of mine, Dr. Wager, whom I have met a few times in Littondale and Wharfedale, showed me once some photographs he had taken, using the cells in various leaves as small lenses, and very clear and sharp were the pictures he obtained, even portraits of people, unless my memory deceives me. Now, if it be possible to photograph objects by such lenses, how great a concentration of heat in selected spots may be expected, what diffusion and refraction of light and gathering into one focus the rays most chemically active undiluted by the feebler sort ! And I fancy that at the same time he told me that chlorophyll and many other substances are capable of making formaldehyde on exposure to light even in the absence of carbonic acid, which I find difficult to understand, although I do not doubt the fact.

Sir, as for the other subjects, you have invited me to write upon, your partiality towards my small abilities persuades you, I fear, that I am able to do more than is in my power. Nevertheless, I will make an attempt, and am, with all respect, &c., &c.

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

Mr. Chaston Chapman's Letter

in your issue last week is, as might be expected, the most polished and temperate statement on the use of the title "Chemist" which I have seen. The controversy which rages round this topic every now and then has, so far, led nowhere, and I am inclined to think this is largely due to the manner in which, up to now, it has been conducted. We must not forget our history. The title "Chemist" was conferred by an Act of 1868. Later the Institute of Chemistry was founded, and it is worthy of note that among those who assisted in establishing the Institute was the then President of the Pharmaceutical Society (Michael Carteighe). So that in those days there was no thought of any clashing of interests between the two bodies. The title "Pharmacist" is of more recent date, and was first introduced, I think, in the Poisons and Pharmacy Act of 1908. The position, therefore, is that the pharmacist has the title "Chemist," and that while he also has the title "Pharmacist," he has only had it for fifteen years, and this is not a long time as things go in which to educate the public. I have listened to so many embittered conversations on this subject that I welcome the tone of the letter from the President of the Institute of Chemistry, and shall be interested to read what the President of the Pharmaceutical Society has to say about it.

The Institution of Chemical Engineers

is now in being. I have watched the growth of this new body with some interest, not to say anxiety. When the project was first mooted I was afraid it was doomed to failure because nobody could tell me what a Chemical Engineer was, and if you could not tell what a Chemical Engineer was, how could you have an Institution of them ? But I took heart because as time went on I noticed that, although nobody knew what a fine chemical was, "fine chemicals" not only continued in commerce, but actually remained in an Act of Parliament. It seemed possible that Chemical Engineers—whatever they may be—would be equally persistent. They have been. During the time we were hearing nothing of the proposed Institution, it appears that they were quietly preparing the ground and have now blossomed forth with a Memorandum and Articles of Association and Bye-Laws all complete, to say nothing of the Seal, a drawing of which appeared last week. So far they have been housed at a certain address in Piccadilly, which I decline to advertise further, but I hear they have now obtained premises of their own nearer Westminster. I wonder if this means they are looking for a Royal Charter !

Another New Anæsthetic

has arrived, according to my daily paper. It is called Narcylene and is reported to consist of purified acetylene and oxygen with some oil of pine to mask the objectionable smell of the acetylene. It has always been a surprise to me that our range of general anæsthetics should be so small. Chloroform, Ether, Nitrous Oxide and Ethyl Chloride do not present a wide choice, but Acetylene, even when mixed with oxygen and with oil of pine I should not have expected to join this select body. I wonder whether it will still be in use ten years hence. I remember how keen for news my colleagues and myself were about fifteen years ago, when certain major operations were being performed with what was then a new local anæsthetic—stovaine. All sorts of rumours were about, and the story went that a certain distinguished surgeon had two operating tables in one operating theatre, on one of which he removed a leg from a patient under spinal analgesia, while the patient smoked a cigarette, and then transplanted a tendon from the removed leg to the patient under chloroform on the other table. It was a good journalistic story, but whether it was true or not, I do not know.

Last Week was Memorable

for the visit to London of a number of our distinguished French colleagues. On Thursday Professor and Madame Urbain and M. Paul Kestner were entertained at a small private luncheon party by a number of members of the Council of the Society of Chemical Industry. I heard that the feature of the post-prandial oratory was Sir William Pope's speech in French, in proposing the health of the guests, and M. Kestner's reply in English. In the evening the same guests with the addition of Professor le Chatelier, M. le Bel, M. Gérard, M. Deschiens, and M. Lucien Bonzon were present at the Annual Dinner of the Chemical Society. The President of the Royal Society was there, as well as the heads of all the other societies and associations connected with the science and industry, and the list of all those present comprises everybody you would want to know. Those who heard the speeches told me they were very good, and I can well believe it. For my part the pleasant company around me compensated me for the inaudibility of some of the speakers. There is something—and I cannot define it—which makes this dinner, year after year, very enjoyable, and in a way distinguishes it from other similar functions.

FORTHCOMING EVENTS

Apr. 4. Society of Public Analysts, Chemical Society's Rooms, Burlington House, W. 1, at 8 p.m. (1) "Physiological Standardisation," by Dr. Stanley White. (2) "An Investigation into the Chemistry of the Reinsch Test for Arsenic and Antimony, and its Extension to Bismuth," by B. S. Evans, B.Sc. (3) "The Estimation of Boric Acid in 'Liquid Eggs' and other Foodstuffs," by G. W. Monier-Williams, Ph.D.

Apr. 6. Society of Chemical Industry, *Manchester Section*, at 16, St. Mary's Parsonage, Manchester, at 7 p.m. (1) "The Recovery of Nitrogen from Sewage by the Activated Sludge Process," by E. Ardern, D.Sc., and C. Jepson, M.Sc. (2) "The Activated Sludge Process, Withington Works," by E. Ardern, D.Sc., and W. T. Lockett, M.Sc.

Apr. 9. Society of Chemical Industry, *London Section*, at the Engineers' Club, Coventry Street, W. 1, at 8 p.m. (1) "The Cod-liver Oil Industry of Newfoundland," by S. S. Zilva and J. C. Drummond. (2) "A Study of the Separation of the Gases formed in the N-Butyl-Alcohol-Acetone Fermentation Process," by E. W. Blair, T. S. Wheeler and J. Reilly.

Apr. 9. The Ceramic Society, the Central School of Science and Technology, Stoke-on-Trent, at 7.30 p.m. "Black and Grey Flints," by A. Heath and A. Leese.

Apr. 11. The Institution of Electrical Engineers, *Wireless Section*, Savoy Place, Victoria Embankment, W.C. 2, at 6 p.m. "Magnetic Drum High-Speed Recorder and Key Transmitter," by Dr. N. W. McLachlan.

Apr. 12. The Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C. 2, at 6 p.m. "The X-Ray Examination of Materials," by A. G. Warren.

Apr. 12. Society of Chemical Industry, *Ottawa Section*, University Club, Elgin Street, Ottawa, at 8 p.m. "Electrolytic Iron," by R. J. Trail.

Apr. 12. Institute of Metals, *London Local Section*, Institute of Marine Engineers, 85-88, The Minories, Tower Hill, E. 1, at 8 p.m. Annual General Meeting, followed by a paper on "The Surface Tension of Metals," by S. W. Smith, D.Sc.

Apr. 16. Society of Chemical Industry, *Yorkshire Section*, at the Queen's Hotel, Leeds. "Some Notes on the Production of Alkali by Bacteria as Registered by Different Indicators," by J. A. Reddie.

Apr. 26. West of Scotland Iron and Steel Institute. Annual General Meeting.

Apr. 26. The Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C. 2, at 6 p.m. "The Drive of Power Station Auxiliaries," by L. Breach and H. Midgley.

SOCIETY OF CHEMICAL INDUSTRY

MEETING OF COUNCIL

The monthly meeting of Council was held on Friday, March 9, 1923, the President (Dr. E. F. Armstrong, F.R.S.) being in the chair.

The President intimated that Dr. C. C. Carpenter had accepted the award of the Society's Medal for 1923.

The Council agreed to contribute Ten Guineas towards the publication of the Annual Tables of Chemical and Physical Constants.

The Reports of the Hon. Treasurer and of various Committees of the Council were discussed, and 28 new members (Home 21, Overseas 7) were elected.

A preliminary programme of the Annual General Meeting, 1923, was submitted, and it was intimated that, subject to confirmation by the Annual Meeting at Cambridge, the Meeting for 1924 would be held in Liverpool.

A scheme for organising chemical propaganda in connexion with the British Empire Exhibition 1924 was submitted, and it was agreed to pay over the sum of £250 to the Central Fund of the Exhibition during the present year, with a recommendation to the Council of 1923-4, that if possible, a similar amount should be paid next year. It was also decided that these donations should be made out of the income from the Messel Fund.

ANNUAL GENERAL MEETING, 1923

The Annual General Meeting will be held on Thursday, June 21, at 11 a.m., in the Arts School, Benet Street, Cambridge, and will be preceded by a meeting of the Council at 10 a.m. At the former, members will be welcomed to Cambridge by the Vice-Chancellor of the University, and the President of the Society, Dr. E. F. Armstrong, F.R.S., will deliver his address. The Vice-Chancellor will hold a reception to the Society at the Fitzwilliam Museum at 5 o'clock, and in the evening there will be a reception and dance.

On the Monday, Tuesday and Wednesday of the same week, the International Union of Pure and Applied Chemistry meets in Cambridge and the President of the Union extends a welcome to members of the Society to attend any of the public meetings of that body.

On Friday, June 22, the Society's Medal (1923) will be presented to Dr. C. C. Carpenter, who will then give an address. On the afternoon of the same day there will be an address by Dr. F. W. Aston, F.R.S., on "Isotopes," and in the evening the Annual Dinner of the Society, which ladies may attend, will be held.

On Saturday there will be a visit to Ely.

All communications should be addressed to the General Secretary at the offices of the Society in London until further notice.

NEWS FROM THE SECTIONS

LIVERPOOL SECTION

A paper on "Some Aspects of Fractional Distillation" was read by Messrs. A. Brittain and C. Elliott, at the meeting held on March 16, Dr. J. T Conroy in the chair.

The paper dealt chiefly with the recovery and rectification of volatile constituents of gases such as gasolene from casing-head or natural gas and benzol from coal gas. It was pointed out that the action of a scrubber was similar to that of a fractionating tower. In the scrubber vapour was removed from a gas which was ascending the column by washing it in counter-current with a liquid in which the vapour was soluble. The wash oil leaving the bottom of the scrubber and the gas entering were rich in the vapour. In a fractionating-tower vapours were ascending and a liquid ascending, more or less intimate contact being effected in various ways. The liquid leaving and the vapour entering were both richer in the less volatile component than at the top. In both systems, the vapour and liquid should theoretically be in equilibrium, although this was never attained in practice.

Various continuous systems for debenzolising oils were discussed and also intermittent and continuous systems for the distillation of benzol into crude and refined fractions. The advantages of continuous distillation were that the concentration of the components remained the same at any point in the system, whereas in the discontinuous type the concentration changed as distillation proceeded. Continuous distillation resulted in :—(1) A uniform quality of product ; (2) heat economy due to recovery of part of the waste heat by means of heat interchangers ; (3) saving in labour by avoidance of intermittent fractions. The disadvantages of a continuous system were :—(1) High initial cost ; (2) complicated construction and operation ; (3) sensitiveness to change in condition such as variations in the crude material to be treated. The discontinuous type was more popular, since it could be used with considerable success for the distillation of other materials than that for which it was originally intended.

The various types of columns used industrially were discussed and reference made to the Kubierschky column for the distillation of benzol and other liquids. The efficiency of a column depended on the intimacy of contact between the vapours and the liquid reflux. In filled-in columns where the reflux liquor was allowed to flow over various kinds of solids, a film effect was employed, but there was considerable danger of channeling. In columns such as those with perforated plates or bells, contact was obtained by bubbling the vapours through the reflux liquor flowing downwards from plate to plate. Perforated plates necessitated a reasonably constant velocity of the vapours ; otherwise there was danger of reducing the level of liquid on each tray if the speed fell or of entrainment of the liquid if the speed was too high. The bell type of tray was still the most efficient.

A resolution of sympathy was passed for the relatives of the late Mr. H. H. Froysell, of Liverpool University, who for many years acted as Hon. Demonstrator to the Section. It was also resolved to invite the Council to arrange to hold the Annual Meeting of the Society in Liverpool in 1924.

MEETINGS OF OTHER SOCIETIES

INSTITUTE OF BREWING

At the meeting of the Burton-on-Trent Section, held on March 1. Messrs. J. L. Baker and H. F. E. Hulton read a joint paper entitled "The Carbonic Acid Content of Beer." The carbon-dioxide cycle in nature was briefly described leading up to a discussion of the formation of the gas during the fermentation of wort in the fermenting vessels from which about 100 cubic feet of CO_2 are lost for every barrel of wort (original gravity 1043) fermented, unless special plant is employed to collect it.

Previously recorded values for the solubility of carbon dioxide in beer, water, and dilute alcohol were discussed, and the authors described the apparatus employed by them for estimating the carbon-dioxide content of a large number of draught and bottled beers of all kinds and at all stages of fermentation, bottling, filtering, carbonating, etc. Thirteen years ago the average amount of carbon dioxide in draught mild ale in the London area was under 800 c.c. per litre, and even to-day, with chilled, filtered and carbonated ale delivered in tank-waggons to the public-house, the carbon-dioxide content, which at the brewery may be 1,400 c.c. per litre, sometimes shows a decided fall by the time the beer is actually served. This loss is particularly noticeable at the later houses reached in the round supplied by the tank-waggon, owing to the splashing about of the beer in the partially emptied space during transit, although such loss may be considerably lessened by maintaining a pressure of carbonic-acid gas in the tank during delivery. The engine used for raising beer from the cellar to the counter was not found to be nearly as responsible for the loss of gas as is generally believed.

The paper was illustrated by slides showing in graphical form the carbon-dioxide content of beer in all stages of its history, and an interesting discussion followed. In some preliminary remarks Mr. Baker alluded to the fact that Burton-on-Trent was widely known as a most distinguished centre of English brewing, and had been associated with the names of Cornelius and James O'Sullivan, Dr. Horace Brown, Peter Griess, and George Harris Morris.

SOCIÉTÉ DE CHIMIE INDUSTRIELLE

The meeting held on February 27 was devoted to the presentation of a paper on "German Industry" by Monsieur Victor Cambon. The lecturer, who was already intimately acquainted with the organisation of German industry in pre-war days, has had the opportunity of obtaining still further information recently during repeated visits.

The subject treated by M. Cambon was the development of the coal and metallurgical districts of the Rhine and Westphalia, districts with an area of 3800 square km., a total production of 100,000,000, tons of coal, and a population which has increased from 2,300,000 in 1905 to 3,700,000. Along with this development, works, towns, railways and water-ways have been constructed and one result has been the exploitation on scientific lines of the lignite deposits of the Saale Valley, mostly used locally in enormous electric generating-stations such as that at Golpa near Bitterfeldt, which develops 150,000 horse-power and supplies Berlin. These lignites are also utilised locally by the synthetic-ammonia factory at Launa near Merseburg, belonging to the Badische Anilin und Soda Fabrik, and which has a capacity twice that of the Oppau works.

Amongst recent industrial developments, mention may be made of the manufacture of sulphuric acid from gypsum, a process due to the necessities of the war, but subsequently modified by the Bayer Co., of Leverkusen, which utilised gypsum and coal intimately mixed in definite proportions and finely powdered. On calcination, this mixture yields cement, and leaves sulphuric acid as a by-product, the operation being carried out in rotary furnaces 60 m. long, heated to 1100° to 1200° C. A daily production of 80 m. tons of sulphuric acid is said to have been attained. Another new industry consists in the recovery of coke from slag, either by electro-magnetic separation, or by the wet process of Meguin. By this means, 250,000 to 300,000 tons of coke could be recovered, and the remaining slag used for brick-making. Further advances are the construction of trucks to carry 50 tons of coal on rail; improvements of enormous gasometers without water seals; and the development of an important union of automobile manufacturers working on the mass-production system.

Referring to further advances in the utilisation of waste products, the speaker described the installation recently at Berlin of a factory in which vegetable debris, sawdust, paper, etc., are carbonised in special furnaces to yield tar, charcoal, and gas, used to drive internal combustion engines coupled with electric dynamos. In conclusion a survey was made of the possibilities of developments of the water-transport system in Germany.

BRITISH CHEMICAL STANDARDS' MOVEMENT

At the meeting of the co-operators in the above movement held at York on February 9, a "Report on the Second Three-Years' Working" (ending September 30, 1922) was read, and a list was given of 53 Analysts who had taken part in the work of standardisation, and of 20 firms who had provided material. Ten new samples comprising 46 actual standards were described; a chronological list of standards was shown; and copies of the 32 certificates issued, British, French and Italian price lists, and diagrams illustrating the preparation of the standards, were exhibited. The extreme precautions taken to ensure perfect homogeneity were detailed and it was stated that every means was used to meet difficulties, and to warrant the confidence of users.

Within six years the movement had steadily developed, in spite of the adverse conditions of recent years. Commencing with a few co-operators in three or four localities in Great Britain, the movement now included members from several countries, some 15 to 20 co-operators taking part in each standardisation. The 23 samples produced, comprising 83 standardized results had covered practically the whole range of plain carbon steels in regular use and included four alloy steels as well as two cast irons and a basic slag. The weight per standard had arisen by 20 or 25 times, and hence the utility had increased proportionately; yet the quality had not merely been maintained, but improved. Now not only most of the large works' laboratories and many public ones in this country used these standards, but their use had so spread that sole agents had been appointed in Italy and France. The 450 British and foreign users included 10 Government Departments, 30 universities and technical schools, and five railways.

Financially, though there was still a deficit, the situation was improving and the movement was gradually progressing towards being self-supporting. The organisation was not restricted to any one Society, Country or Industry, and therefore had a world-wide choice of co-operators, and was able to select for each type recognised specialists in that class of analysis. The work had demonstrated the necessity of standard samples to reveal divergencies in analytical results and that the methods used for iron and steel standards could be applied equally well to other materials. It was hoped that the fullest use would be made of the standards to ensure continued extension of the movement and to make it financially self-supporting. A committee was formed to report on the formation of a more formal organisation with separate headquarters, and a resolution was passed urging engineering and chemical societies to bring before their members the scientific and practical value of chemical standards.

CORRESPONDENCE

THE WORD "GAS"

SIR,—In the Editorial Notes of the current issue you make reference to the origin of the word "gas." There is no doubt that it was first used by Van Helmont (1577–1644), the occasion being in a work written by him and published after his death, *Ortus Medicinæ* (1648). He says, "*halitum illum Gas vocavi, non longe a chao veterum secretum*" ("I have called this spirit Gas, it being scarcely distinguishable from the chaos of the ancients"). He used the word in the course of his description of the gas now known as carbon dioxide, and prior to Van Helmont's time known as *spiritus silvestris*. There is no earlier indication of the derivation of the word "gas" than that given in *Ortus Medicinæ*, and the alleged derivation from the Dutch *geest* or German *geist*, *gascht*, or *gast* is one of much later date than the time of Van Helmont. It was Joseph Priestley in his work, *Experiments and Observations on Different Kinds of Air* (1775), who ascribes to the word *geist* (spirit) the origin of "gas," and Cavallo in his *Treatise on the Nature and Properties of Air* (1781) says: "The word *gas* is derived from the German *gascht*, or *gast*, which signifies an eruption of wind." When it is recalled that the alchemists described the gaseous state in such terms as *spiritus*, *flatus*, *halitus*, words signifying "wind" or "breath," and that in German this is rendered *geist*, it is easy to understand how Priestley accounted for "gas" as being derived from *geist*. The fact, however, is clear, that a hundred and twenty-seven years prior to Priestley's book being published, Van Helmont, after remarking on the incoercible character of *spiritus silvestris*, and comparing it to the Greek *chaos*, invented the term "gas."—I am, Sir, etc.,

THE UNIQUENESS OF HYDROGEN

SIR,—The editorial on page 252 of the issue dated to-day occasions two comments.

"Uniqueness of Hydrogen." The non-existence of any accurate determinations of the mass to inertia ratio for hydrogen is very curious, if not unique, for a common element. The need for this ratio in certain speculations prompted inquiries to the recognised authorities, but no determinations by reversible pendulum methods could be found. One authority suggested tetrapropylammonium fluoride for such experiments as being the solid with the highest hydrogen content.

"In the case of units of electricity, at any rate, attractiveness is not a function of mass." Conjunction with matter is an essential for electrical attraction and/or repulsion. Free electricity, represented usually by waves, has not this property of attraction.

Electrostatic attraction. Assuming that electrons are units of electricity, the Cavendish proof of the inverse square law fails for small quantities if the attraction and/or repulsion is of electrons *per se*. Postulating the attraction as a secondary effect, the conjoint effect of electrons and matter, it is easy to envisage the necessary uniform distribution on the spherical surface assumed in this proof.

Electro-magnetic attractions. Electrons with the velocity of light in parallel streams could not have mutual actions; as the attractions and/or repulsions have only the same speed of propagation as the velocity of travel, no pair of electron could have mutual actions. The effect of streams of electrons travelling along wires with the velocity of light on each other would similarly be *nil* if Newton's law that action and reaction are equal be true.

If electricity in motion of itself produced magnetic effects then these would result from the rotation of a charged non-conductor. In Rowland's experiment conducting studs were used. Two vectors are here concerned; change of motion, or orientation, of the electrons free to move within the studs measured by the vector radius and the electron momentum. The vector product is the magnetic effect perpendicular to the plane. With parallel currents the effects can be simply deduced from the secondary disturbance caused by the passage of the electrons through matter, propagated with the velocity of light.—I am, Sir, etc.,

INVISIBLE INK

SIR,—Is it possible to make an "invisible ink" which, when applied to paper, will become visible an hour or two later without putting the paper through any process such as heating, etc.? If so, I should be grateful if you would tell me how it is done. This, I may add, is in connection with a conjuring trick.—I am, Sir, etc.,

BAYBERRY OIL

SIR,—May I thank the gentlemen who so kindly replied to my query *re* the above. The information I received was of the greatest possible use to me, and was instrumental in enabling me to solve a most difficult problem.—I am, Sir, etc.,

Birmingham W. LESLIE CARTER
March 23, 1923

THE TITLE "CHEMIST"

Sir,—In the *Liverpool Daily Post* for March 9, an account of Major Lefebure's lecture on "Chemical Warfare," under the title "Chemists in Warfare" appeared next to a two column advertisement of the Pharmacist's Retail Association, headed in one-inch letters, "Chemists." This sort of thing is very misleading to the general public who might anticipate reading something about Number Nines in the article on Chemical Warfare. The younger members of the Institute of Chemistry are to be encouraged in their efforts to obtain for the name "chemist" the same meaning in English as it has in most other languages.—I am, Sir, etc.,

E. M. Shepherd

PERSONALIA

The honorary degree of D.Sc. of Manchester University is to be conferred on Mr. W. B. Worthington, President of the Institution of Civil Engineers, 1921-1922.

Prof. A. C. Seward has been elected President of the Geological Society for 1923-24.

Dr. Wilder D. Bancroft has been elected Editor in Chief of the *Journal of Physical Chemistry*, now controlled by an editorial board of English and American physical chemists.

Mr. C. S. Garland, M.P., managing director of the Volker Lighting Corporation, has been appointed by H.M. the King in Council to the Governorship of the Imperial College of Science, vacant through the resignation of the Hon. N. Rothschild.

The Institute of Mining and Metallurgy has awarded its Gold Medal to Mr. Edgar Taylor for his work on Indian mining, the Consolidated Gold Fields Medal to Dr. Leonard Hill for his paper on ventilation and human efficiency, and the Gold Fields Premium of 40 guineas to Mr. H. F. Collins for his paper on the igneous rocks and the pyritic ore-bodies of Huelva.

* * *

With the death of Prof. H. H. Stoek, the American coal industry loses a prominent investigator in the field of coal technology.

With regret we announce the death of Sir James Dewar, F.R.S., at the age of 80. We hope to publish an obituary notice in a later issue.

From Germany the deaths are announced of Dr. F. Bössenecker, chemist to the Chemischen Fabrik Griesheim-Elektron; Prof. E. von Raumer, formerly director of the Untersuchungsanstalt für Nahrungs- und Genuszmittel, Erlangen; and of Dr. H. Franzen, professor of biochemistry in the Technical *Hochschule*, Karlsruhe.

NEWS AND NOTES

AUSTRALIA

Gold Discovery in Western Australia

It is announced officially that a narrow interrupted belt of auriferous country, about 50 miles long, with good gold prospects, has been found in the district east of Mt. Shenton, and about 100 miles north-east of Lavator, a terminus of the Kalgoorie railway. The discovery is regarded as promising, but is as yet quite undeveloped.

BRITISH INDIA

Final Forecast of the Sugar-Cane Crop, 1922-23

The final general memorandum based on reports received from provinces containing 99 per cent. of the total area under sugar cane in British India estimates the area sown at 2,721,000 acres and the total yield of raw sugar at 2,988,000 tons, increases of 14 and 15 per cent., respectively. The condition of the crop is reported to be generally good. In addition to the area to which the above estimate applies, the crop is grown in certain other regions in British India which have an estimated annual production of 24,000 tons. The importance of the Indian sugar crop can be realised when it is stated that the world's production of cane sugar in 1922–23 is estimated at 12,676,000 tons, an increase of 10,000 tons over that of the previous season.—(*Ind. Tr. J., Feb.* 22, 1923.)

FRANCE

Notes from Paris

The Convention concluded recently between France and Poland is of particular interest, for it provides that both Governments are to collaborate not only in general political matters, but also in the development of the petroleum industry. The French Government does not participate directly but acts through French companies established in Poland. In exchange for the services of the technical experts and for the capital provided by these companies, the Polish Government undertakes to give the French companies preferential treatment over other foreign companies in Poland. The preference so guaranteed will naturally place French companies operating in Poland in a most favourable financial position.

Certain resolutions passed by the Chamber of Deputies relating to the "National Fuel" have been discussed by the Senate. These resolutions lay down that importers of petrol must purchase from the State a minimum of 10 per cent. of ethyl alcohol. Importers of petroleum products destined for the chemical and dyestuffs industry are, however, exempted. Contemporaneously with this discourse, Monsieur de Berthelot was speaking before the Société des Ingénieurs Civils on the present state of the "National Fuel" question. After discussing the various scientific, technical and economic aspects of this question, Monsieur

Berthelot insisted that the problem could only be solved by the utilisation of a mixture of petrol and 40 to 50 per cent. of absolute alcohol, a mixture which had been found satisfactory in the course of tests extending over eighteen months. Of other solutions of the problem, the recovery of benzole from gas, the exploitation of lignites and shales, and the use of catalytic processes for producing liquid products from solid hydrocarbons, are only for the future, and for France the only method appears to be to intensify the production and use of alcohol. There is nothing new in the use of alcohol as a motor fuel, the first trials dating from 1900, but the question was complicated by the numerous taxes which affect the market prices of alcohol, and by the State monopoly of alcohol declared in June, 1915. This monopoly, however, reduced the human consumption of alcohol by two-thirds, and made it necessary to seek a new outlet as a motor fuel.

The public interest shown in chemical problems is further evidenced by a meeting held at the Sorbonne on March 3, under the auspices of the Red-Cross Society, to support the adoption of the resolutions carried at the third International Labour Conference at Geneva concerning the uses of white lead. The dangers arising out of the use of white lead were discussed, but it is certain that other products which are economically and technically suitable as substitutes are hard to find.

UNITED STATES

Antimony in 1921

According to a recent Report of the United States Geological Survey, the United States has produced no antimony ore since 1918, the total output during the period 1915–1918 being 10,750 short tons of ore carrying 4310 t. of metal. Small amounts of metallic antimony were produced at smelters in 1919–20, but the figures are not available for publication. Although there was no production in 1921, there was an output of by-product antimonial lead from foreign and domestic ores, amounting to 10,064 t., with an antimony content of 1589 t., and 4720 t. of antimony in the form of alloys was recovered from old alloys, scraps and dross. Imports of antimony ore in 1921 amounted to 213 t., of antimony matte 353 t., of metal 10,130 t., of antimony oxides and compounds 154 tons. The chief source of the metal was China, which supplied 20,530,079 lb., followed by Japan with 302,750 lb., and England with 302,457 lb. The world's yearly peacetime consumption of antimony was about 22,000 m.t., of which the United States consumed 10,000 tons, in addition to about 2100 t. of virgin antimony contained in domestic antimonial lead, and 3500 t. of secondary antimony recovered from alloys, etc. Over 60 per cent. of the world's production is derived from China, but important deposits occur in Canada, Mexico, Argentina, Bolivia, Peru, France, Italy, Turkey, Algeria and Australia.

Metallic antimony is used chiefly as a constituent of alloys. The oxides are used for making white enamel, and the oxide and sulphide as colouring agents in paint pigments. The field of use for antimony compounds, especially for the oxides in paint, is rapidly widening. A successful substitute for antimony as an agent for hardening lead is said to consist in a compound of calcium and barium.

GERMANY

Wages in the German Chemical Industry, 1922

The following figures show the enormous increase in wages which occurred in the German chemical industry during 1922.

	Average weekly wage (marks)					
Month	Operatives		Process workers		Unskilled workers	
	Single	Married*	Single	Married*	Single	Married*
Pre-war	32·96		26·81		23·85	
1922

Metal Linings by the Spray Process

The spraying of molten metal on to surfaces in order to produce metallic coverings is no new process, and yet it has not been completely successful in the past. The covering obtained hitherto possessed a somewhat porous texture, an undesirable quality in resistant linings for chemical apparatus. Now, however, it is claimed by the director of the Metallisator-A.-G. (Altona), that thoroughly satisfactory tin, lead, aluminium and copper linings can be produced on iron by subjecting the sprayed metal coat to a finishing process, which may be either mechanical or chemical, or both. The lining may be rendered more coherent by hammering; or the pores may be filled up with some chemically resistant material, *e.g.*, in the case of a lead lining, with lead sulphate obtained by treating the lining with sulphuric acid. The great advantage of these sprayed linings over the usual laid-on ones lies in their close contact with the substratum, an important factor in apparatus with walls through which heat is to be transferred. Unfortunately the publication of the details of the methods is postponed owing to patent proceedings.—(*Chem.-Z.*, *Jan.* 11, 1923.)

GENERAL

Strontium Minerals, 1913-1919

A digest of statistical and technical information relating to the production of strontium minerals during the period 1913–19 has been published by the Mineral Resources Bureau (pp. 12. Price 3d.) The pamphlet reviews the sources and properties of the chief strontium minerals, celestite and strontianite, and states that the chief uses of strontium compounds are in sugar-refining and pyrotechny, as a substitute for barytes in fillers, and in the manufacture of glass and medicines. The world's production of strontium minerals has fallen from 18,425 long tons in 1913 to 4,319 t. in 1920 and 7,232 t. in 1921. The output in 1921 consisted of 6,622 t. of celestite produced in England and 610 t. of strontianite in Germany. Both minerals occur in Canada, but the deposits of strontianite appear to be of no commercial importance (see *Chem. and Ind.*, 1923, p. 80.). Occurrences are recorded from India, Canada, Germany, Sicily and the United States (*cf.* J , 1922, 176 R), but it appears that production from these localities cannot compete with that of England. The pamphlet concludes with a series of bibliographical references to chemical literature relating to the uses, occurrences, and mining of strontium minerals.

Mexican Poppy Oil

The oil of the Mexican or prickly poppy (*Argemone mexicana*) is used to some extent medicinally in India and the West Indies, and is reported to possess purgative properties. It is also used as a lubricant and illuminant in Mexico and the West Indies. From its moderately high iodine value, the oil would be classed as a semi-drying oil, and it is stated to be employed in South America in paint-making. Experiments carried out at the Imperial Institute indicate that the oil would not be satisfactory for paint making, though it might be employed in admixture with linseed oil as a cheap substitute for the latter. The bitter taste and therapeutic action of the oil make it unsuitable for human consumption, and the only possible commercial use would appear to be in soap-making. The meal left after extracting the oil could not be used as cattle food, and therefore could be utilised only as a manure, a purpose for which it would be of value on account of its large content of nitrogenous compounds.—(*Bull. Imp. Inst.*, **XX**, *No.* 3, 1922.)

REVIEWS

Paracelsus. *By* Prof. J. M. Stillman, *of Stanford University. Pp. viii.*+184. *London : The Open Court Publishing Co.*, 149, *Strand, W.C.* 2. 1920. *Price* 10*s*.

In the history of chemistry, Paracelsus is a great name. Nevertheless, his actual achievements in that science are somewhat problematical. Professor Stillman's biography gives an interesting account of this exceptional man, but adds little to the knowledge we already possess of the chemical side of his activities. This was to be expected. Theophrastus Bombastus von Hohenheim, commonly called Paracelsus, was born in 1493 at Einsiedeln, now in Switzerland. He studied mining in Carinthia and the Tyrol, and became an army surgeon or physician in Denmark and Sweden. He travelled over the greater part of Europe, sometimes practising as a physician, but always quarrelling with the orthodox practitioners, for whom he appears to have maintained the utmost contempt. A theologian of some acuteness, he engaged in controversies in theology. He died at Salzburg in 1541, at what we should now consider the early age of forty-eight.

The chief characteristics of Paracelsus as a man were his power of clear thinking, his contempt for all knowledge not the result of direct observation and his underestimation of the strength of the traditions, skill and inertia which he was bound to find opposed to him. He had a wide conception of alchemy as the following quotation from his writing shows : "For the baker is an alchemist when he bakes bread, the vine-grower when he makes wine, the weaver when he makes cloth." As a teacher of medicine he refused to teach the ancient books, and taught according to his own experience ; he was defiant and insulting to those who did not agree with him, which did not make for popularity. As a thinker he was unusually self-reliant and independent.

The great service he rendered to chemistry was his advocacy of the use of various chemical substances by physicians and his successful application of certain chemically prepared remedies. Like some other reformers, the roughness of his methods interposed a barrier between him and those to whom he preached ; he was an earnest, powerful and prophetic voice crying in the wilderness. He was a voluminous writer, usually ready to enter into a controversy on almost any subject.

The following quotation from his book "*De natura rerum*" may interest some of our readers : "The mortification of lead consists in converting it into *cerussa*, which is also called *Bleiweiss*. Its preparation is in two ways—one in medicine, the other in alchemy. Its preparation in medicine is thus—that you hang lead in thin sheets over a sharp wine-vinegar in a glazed pot. The pot is then well stoppered, so that no spirits may volatilise, and set in warm ashes, or in winter behind the stove: then you will find in ten to fourteen days good whitelead adhering to the sheets which you may may remove with a hare's foot, and again hang the sheets, and do this until you have white-lead enough. The other preparation of white-lead—in alchemy—is like this, except that in the vinegar much of the best and finest salmiac is dissolved. That gives a fine and subtle white-lead."

Professor Stillman's biography is pleasantly written and the type easy to read.

(1) SECOND YEAR COLLEGE CHEMISTRY. *By* WILLIAM H. CHAPIN. *Pp. xii*+311. *New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.,* 1922. *Price* 15*s*.

(2) A MANUAL OF LABORATORY EXERCISES. *By* WILLIAM H. CHAPIN. *Pp. viii*+115. *New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.,* 1922. *Price* 7*s*. 6*d*.

(1) It is almost as difficult to review a second-year text-book as it would be to criticise the second act of a play without knowing what had preceded it or what was to follow. Professor Chapin, however, gives an indication of the ground covered in the first year in his introduction to "Second Year College Chemistry," which represents the course followed by his students in Oberlin College, Ohio. The first year course is "largely given over to descriptive matter"; and acting on the convenient assumption that any generalisations introduced in that course have passed into oblivion, whereas the descriptive matter still survives the summer vacation, the second year is devoted to the revival and expansion of general principles. Hence the volume is really an introduction to physical chemistry, or rather to portions of that subject; for the most noticeable feature is a curious unevenness in the treatment of the topics introduced. Thus, following on a discussion of the kinetic theory, the gas laws and the atomic theory, Chapter VII deals with symbols, equations, etc., in a very elementary manner and introduces the simplest chemical arithmetic. One feels that, if the student requires instruction in such matters, he must be quite unprepared to digest the excellent account of recent work on radio-activity and atomic structure which follows in Chapters X and XI. The sections on the ionic theory, indicators, and electrochemistry are refreshingly up-to-date, although the discussion would have been simplified by the introduction of the p_H notation at an earlier stage. In contrast, it is strange to find two pages devoted to a serious discussion of what is meant by "molar" and "normal" solutions. The action of catalysts is dismissed in one page and thermo-chemical measurements receive no mention.

(2) The laboratory manual, which is intended to be used with the text-book, contains detailed descriptions (sometimes almost too detailed) of sixty experiments, the rest of the time in the laboratory being devoted to qualitative analysis. Many of the experiments are novel at any rate in a second-year course; and, aided by the lucid diagrams, no student should have difficulty in carrying this part of his work to a successful end. The theoretical work dealt with in the lecture room is effectively illustrated without the invidious suggestion that the student discovers laws of nature by two or three simple experiments; and a good deal of quantitative analysis is unobtrusively brought in. It is, however, undesirable that students should set out to determine an equivalent with a previous knowledge of the atomic weight; and the one experiment given to illustrate the law of volumes, in which cupric oxide is reduced by ammonia and the volume of nitrogen produced is alone measured, should be replaced by others.

The manual can be strongly recommended to harassed teachers who have little opportunity to try out experiments for the use of their classes.

P. C. L. THORNE

CAROTINOIDS AND RELATED PIGMENTS. THE CHROMOLIPOIDS. *By* PROF. LEROY S. PALMER, Ph.D. *American Chemical Society, Monograph Series. Pp.* 316. *New York: Chemical Catalog Co., Inc.,*1922. *Price* $4·50.

At the present moment there are five more or less well defined substances included under the term Carotinoids, namely carrotene, xanthophyll, lycopin, fucoxanthin and rhodoxanthin, of which carrotene and lycopin on the one hand, and xanthophyll and rhodoxanthin on the other, appear to be isomeric. Ranging in colour from yellow to red, and having very similar physical properties, these substances nevertheless differ chemically from each other in rather striking manner, inasmuch as carrotene and its isomer are hydrocarbons of the formula $C_{40}H_{56}$, whilst xanthophyll and fucoxanthin are represented by the formula $C_{40}H_{56}O_2$ and $C_{40}H_{54}O_6$, respectively. For carrotene as a hydrocarbon to have such a strong yellow colour is in itself somewhat remarkable, since comparatively few coloured hydrocarbons are known, and it is certainly noteworthy that the introduction of oxygen into the complex should produce substances of much the same colour and general physical and chemical properties.

The very wide distribution of these substances in the plant world is evidenced by the fact alone that chlorophyll is invariably associated with carrotene and xanthophyll and, in the case of the brown algæ, with fucoxanthin as well; apart from this, the carotinoids also frequently occur separately, causing, for example, the high pigmentation of the carrot and of many fruits and flowers, algæ and fungi. The occurrence of carotinoids is, however, not confined to the plant world, since it appears from recent work that many of the yellow animal pigments formerly described as Lipochromes are either true or modified plant carotinoids. With regard to their origin it has now been well established that in the case of man, the higher mammals and fowls, the yellow chromolipoids of their tissues and secretions are derived from the carotinoids of their food. The occurrence of such carotinoid pigments is, however, not universal, even among herbivorous animals, since practically none occur in sheep, goats and swine. In this connexion attention is drawn by the author to the remarkable fact that the cow and the horse resorb the carotin of their rations to the relative exclusion of the xanthophylls, although the latter are more abundant in their food, whilst with the fowl the conditions are reversed.

To those seeking information regarding the distribution and occurrence of carotinoids in any particular group of plants or animals, this monograph will be found to be invaluable, since separate chapters are devoted to each main division of the plant or animal world. Other chapters are devoted to the biological relations between plant and animal carotinoids, and to the methods of isolation, identification and quantitative estimation of carotinoids, and their possible function in the plant and the animal. The fallacy of the view at one time current, especially in America, to the effect that vitamins and carotinoids were identical is dealt with in the last chapter. Here also attention is drawn to a practical aspect of the question—namely, that there is a correlation between low pigmentation of the visible skin parts of certain breeds of fowls and high egg production; this is attributed to a selective mobilisation of pigment in the ova preventing its excretion by means of the skin. One other significant example of the application of scientific knowledge concerning the association of carotinoids with chlorophyll is mentioned in the preface, where attention is drawn to the fact that by employing from aeroplanes, during the late war, light filters absorbing practically all light rays except a wide band in the red, and a narrow band with low transmission in the green, natural green foliage appeared red, whilst camouflaged foliage, on which only green paint was used, appeared green. Each chapter is provided with a useful summary, and at the end of the book will be found a comprehensive bibliography. Throughout the text and in the index are to be found a great many mis-spellings of plant names, of which only a few need be mentioned, such as *Ribus glossularia* (for *Ribes grossularia*), *Odintiglossum*, *Nicotinia tabacum*, *Philobolus Doronium*, etc. These are, however, minor blemishes which can be put right in a later edition, and do not detract seriously from the value of the book, which forms a very valuable compendium of an extensive subject set forth in a very attractive and readable form.

PAUL HAAS

PLASTICS AND MOLDED ELECTRICAL INSULATION. *By* E. HEMMING. *Pp. vii*+713. *New York: Chemical Catalog Co., Inc.*, 1923. *Price* $5.

During the past twenty years the use of plastic materials has increased so greatly that a single volume dealing with them should be widely welcomed, even though it is, of necessity, far from exhaustive. The present work consists essentially of two parts, of which the first is devoted to clay products, cements, artificial stones, glass, casein products, road-materials, adhesives, linoleum, artificial leather and silk, rubber, paper, cellulose and sundry other plastic compositions, whilst the second part is devoted almost exclusively to moulded insulating materials.

The second portion of the volume is of much better quality than the first, but this is not surprising, as it deals with a subject with which the author has been chiefly concerned for many years.

Any reader who looks for a scientific treatment of the subject will be disappointed. No definition of plasticity, or of its causes is given, but the author makes it quite clear that, for most purposes, a material must not only be plastic, but must be capable of being hardened by some simple process. On the contrary, the volume consists largely of a compilation of technical matter, much of which appears to have been selected in a somewhat haphazard manner. For instance, nearly four pages are devoted to refractory bricks, but building bricks and tiles do not appear to be mentioned. Similarly, in the section on dental cements, no information is given to show that commercial zinc oxide is useless unless subjected to a preliminary treatment which renders it more compact. The section on silicate dental cements is particularly disappointing.

The most valuable portion of the book commences on p. 205 and deals with the author's method of "cold-moulding mixtures of silica, asphalt, and resin for insulators and other articles used in the electrical industry," because this section is not merely a compilation, but contains some of the results of the author's own experience. Even here, however, the information given is so slight as to be of little use to anyone wishing to make articles of the kind described, though users of moulded articles will find numerous useful suggestions to aid them in specifying which class of composition will best suit their purpose. It is also instructive to observe that in the author's opinion, "No electrical engineer wants to replace porcelain, but has to, because of the lack of stimulant and progress on the part of the porcelain manufacturer."

At the end of the sections is a list of Patent Specifications with brief notes on each. None of these patents is earlier than 1907, and the lists are incomplete as regards British, French and German patents. This partly arises from the author's opinion that " there is an enormous number of others . . . of no value or interest."

The volume should be very useful to those who require a brief though superficial survey of the various plastic materials and their uses. It would be greatly improved by the inclusion, at the end of each section, of a short list of books or papers dealing with that branch of the subject, and by abstracts of the more important of the patents granted prior to 1908. The latter would be particularly useful to those whom the author describes as " inventors not familiar with the properties and the purposes for which the inventions are intended " and might save much useless expenditure on " combinations which are really no invention, as they were probably known before the patentees were born."

Alfred B. Searle

An Advanced Laboratory Manual of Organic Chemistry. *By* M. Heidelberger, Ph.D. *Pp.* 103. *New York: Chemical Catalog Co., Inc.*, 1923. *Price* $2.

This is an interesting little collection of organic preparations, some of which are rather difficult, chosen to stimulate and test the manipulative skill of the advanced student.

Each chapter deals with preparations involving a definite operation or group of operations, such as nitration and nitrosation, but as the number of preparations given altogether is not large, it is not surprising that the examples chosen cover the unusual or lesser-known types of reactions. For the same reasons the compounds prepared are for the most part chiefly of theoretical interest. At the same time some products of technical importance are described, and there is an excellent chapter which deals with organo-metallic preparations, involving the direct arsenation of phenol and the direct mercuration of aniline. These operations typify reactions, which now almost rank with the standard operations of organic chemistry in general applicability.

References are mostly given to the work of the original investigators, but it is evident that the author and his colleagues have worked through many of the original processes and presented them in a modified form.

In the text, the author discusses the more theoretical aspect of the changes involved in the experiment in hand, and occasionally he describes the effect of any change in procedure on the proportions of the position isomers and such matters. One would have liked to see the author discuss the question of yields in the same way, or at least direct the student to think about it. In the " Veronal " synthesis, attention is called to the need of having all the re-agents absolutely anhydrous in order to secure good yield, and in another place a poor yield is explained by the fact that phenols readily oxidise, but otherwise the value of the quantitive aspect of the work is neglected. Surely the student should be directed to consider why an excess of a reagent or a solvent is used, what its function is and what would happen if it were not there or applied in another way ? If, as the author says, it is his ambition " to provide as broad a foundation as possible for the student's work," then the student might well have been directed to the economics of some of the operations with the view to studying the factors which affect them. When the yield of a preparation is less than 50 per cent. then the other 50 per cent. should hardly be allowed to go down the sink without comment. After all, when the student gets into the manufacturing laboratory he will find that it is the other 50 per cent. that matters.

L. A. Jordan

REPORT

The Cleaning and Restoration of Museum Exhibits: Second Report upon Investigations Conducted at the British Museum. *Department of Scientific and Industrial Research. H.M. Stationery Office*, 1923. *Price* 2*s. net*.

Prints and Pictures.—The method of restoring white-lead preparations on drawings and bleaching foxed marks on engravings in which the surface is exposed to hydrogen peroxide vapour (this J., 1922, 23 R) has been in constant use and with great success for both purposes. A warning is given, however, as to the action of hydrogen peroxide on the sizing of certain kinds of paper, which, under the prolonged treatment often required, become fragile and brittle. In other cases where drawings supposed to have been executed in sepia have, in reality, been done with an ink with an iron salt basis, the lines have been bleached to a faint yellow by the hydrogen peroxide, whereas real sepia remains practically unaffected by the reagent. Careful treatment with potassium ferrocyanide and ammonia will, to a large extent, restore the original details of a bleached iron ink, but this experience shows that a preliminary test should be made upon a small portion of a drawing before exposing it to the vapour.

To ascertain whether the pigment in a drawing consists of sepia or bistre, a minute drop of sodium hypobromite is applied : sepia turns red before being bleached, whilst bistre does not turn red, and is only imperfectly bleached, residual black specks appearing on the bleached surface. Stains of an organic nature probably due to red ink or red dyes can be readily removed by applying a solution of sodium hydrosulphite (" Hydros "). When the paper is very thick a solution of hydrogen peroxide in ether may be applied to the blackened pigment by means of a soft brush.

Pigments showing a tendency to flake off from the surface can be fixed by treatment with a solution of cellulose acetate in acetone ; and the same medium has been used for preserving mural tablets, and for attaching decayed paintings on silk to a cloth basis.

Stone and Earthenware.—Experiments are described showing the chief types of salt causing the destruction of stone. Extracts from specimens of material which had crumbled from three different objects (all of limestone) contained : (1) Ammoniacal salts and free ammonia ; (2) sulphates chlorides, nitrates and calcium, but no ammonium salts ; and (3) calcium sulphates and chlorides, magnesium, but no ammonia or nitrates. The disintegration is to be attributed to the crystallisation of the less hygroscopic salts in the pores of the stone. Preservation of stone and earthenware is therefore effected by removing the soluble salts (derived from external sources) by washing.

Silver.—When formic acid does not readily remove incrustations as previously described (*loc. cit.*), resort may be had to the use of zinc dust and very dilute sulphuric acid.

Lead.—The solutions previously recommended (*loc. cit.*) have been successfully used on numerous objects. Some of these have been coated with a varnish of about 5 per cent. of celluloid dissolved in a mixture of equal parts of acetone and amyl acetate. The distortion of the surface of objects of lead caused by decay has been found to be due to the most active corrosion taking place in the interior of the mass, and a resulting expansion which ruptures the surface

Copper and Copper Alloys.—A suitable alkaline solution for cleaning copper, brass and bronze when the acid solutions previously described are not admissible consists of 3 parts of Rochelle salt and 1 part of caustic soda in 20 parts of water. The use of granulated zinc in association with 5 to 10 per cent. caustic soda solution has also proved an effective cleaning agent.

Wooden Objects.—The best solvent for extracting the ammonium salts, to the crystallisation of which disintegration is frequently due, has been found to be dilute (about 5 per cent.) acetic acid, followed by repeated soaking in water, immersion in 0·5 per cent. mercuric chloride solution, and final treatment with a celluloid varnish. Ravages due to insects, are best prevented by treatment with carbon disulphide or hydrogen cyanide vapour. Chloroform, tetrachlorethane are dangerous where coloured objects are in question owing to the possibility of free chlorine being liberated after exposure to light. Experiments with a painting containing flake white (white lead) showed that the picture film, varnish, oil and pigment did not absorb carbon disulphide from wood which had been saturated with that compound in liquid form.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for March* 22)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Australia ..	Crockery, porcelain ..	*
British India	Brass and copper tubes	368, 373
British West Indies ..	Metals, chemicals, drugs, oil, grease, explosives, paint, laboratory equipment, and other mining supplies ..	370
Canada ..	China, earthenware, druggists' supplies..	372
Egypt ..	Oil, paint, varnish ..	10205/F.E./C.C.2
France ..	Pharmaceutical products, etc.	378
Italy ..	Metals, alloys.. ..	379
Morocco ..	Sugar	386
Netherlands .	Rubber goods.. ..	380
South Africa	Earthenware	375
,,	Iron piping	9935/E.D./E.C./A.2
Spain ..	Coal	383
United States	Calcium arsenate, white arsenic	5411/B./T.C./C.C.

* Ref. No. Com. 412/7/1/192. Official Secretary, Commercial Bureau, Australia House, Strand, W.C. 2.

TARIFF CUSTOMS EXCISE

Colombia.—A consolidated duty, consisting of the import and consumption duties, is applied to alcoholic beverages, pharmaceutical preparations, patent medicines, and perfumery.

France.—More favourable tariff treatment has been applied to wood sawdust, cellulose pulp, newsprint paper, magnesite bricks, and electric lamps of Austrian origin. The text of the commercial convention with Canada is given in the issue of March 22.

Greece.—Modified import duties have been applied to raw gums, waxes, turpentine, mineral oils, various metals, soap, starch, glue, leather, earthenware, glass, photographic plates, and emery and glass paper.

Hungary.—Special import licences are required for gas coke, wrapping paper, photographic paper, salicylic acid, and various wares of leather. X-ray apparatus, quartz lamps, and glove leather may be imported without licence.

Palestine.—The customs duties on motor fuel, spirits, etc., sugar, perfumes, and perfumery essences have been revised.

Rumania.—Modified export taxes are leviable on benzine, lamp, gas and mineral oils, and paraffin wax.

Switzerland.—Increased export duties have been applied to scrap and waste of iron, brass, and copper.

PARLIAMENTARY NEWS

Safeguarding of Industries Act

In a written answer Major Boyd-Carpenter informed Sir R. Hamilton that the revenue received under the above Act during the current financial year up to March 10, amounted to £509,000.—(Mar. 19.)

Imports of Dyestuffs

Lieut. Col. Buckley, replying to Mr. Short, said that the imports into the United Kingdom of Alizarin and Anthracene dyestuffs during 1913 were 60,813 cwts., valued at £272,245, compared with an import of 11,387 cwts. of Alizarin dyes, valued at £60,607, in 1922. Owing to changed classification, separate particulars of imports of Anthracene dyes in 1922 were not available.—(Mar. 19.)

West African Palm-Oil Industry

Answering Mr. C. Roberts, Mr. Ormsby-Gore stated that means of assisting the West African oil-palm industry to meet Dutch competition had been engaging the attention of the Colonial Office and the West African Government for several years. In Nigeria and the Gold Coast the Agricultural Departments were being strengthened to enable experts to investigate the industry, and to develop better methods of cultivation and extraction.—(Mar. 19.)

Unemployment in the Paper Industry

In reply to Mr. Becker, Mr. Betterton said that he had no information of the number of paper mills now closed. Out of 61,000 workpeople insured against unemployment in the paper-making and staining trades, 4528, or 7·4 per cent., were registered as unemployed at February 26. It was not possible to say how much unemployment was due to foreign competition.—(Mar. 20.)

The Gas Industry

Mr. P. Lloyd-Greame stated in reply to Mr. F. Gray that he was communicating with representatives of the gas industry in regard to the recommendations in the recent report of the Departmental Committee on the sale of gas by the therm, and he hoped it would be possible to give effect to the report without legislation.—(Mar. 20.)

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech. ..	£23-£25 per ton. Very firm with little available. Complete absence of German supplies.
Acid Hydrochloric ..	4s.-5s. carboy.
Acid Nitric	£24 per ton. No signs of improvement.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw., is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% arsenical	£6 10s. per ton.
Ammonia Alkali ..	£7 12s. 6d.-£8 per ton. Steady demand. Continental inquiries more frequent.
Arsenic (White) ..	£70-£75 per ton. Market steady.
Bisulphite of Lime ..	£7 per ton. Packages extra.
Bleaching Powder ..	£10 10s. d/d. No change. Spot demand poor.
Calcium Chloride ..	£6 per ton d/d.
Copper Sulphate ..	£27 per ton. Somewhat firmer.
Potash Caustic, 88/90%	£35 per ton. Considerably advanced in value. No German supplies.
Potass. Bichromate ..	6¼d. per lb. d/d.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton. Normal.
Soda Caustic, 76% ..	£20-£21 per ton. Demand good, especially for the Continent.
Soda Crystals	£5 5s. carr. paid. No change. Demand quite good.
Sod. Bicarbonate ..	£10 10s. per ton.
Sod. Acetate, 97/98% ..	£25 per ton.
Sod, Bisulphite Powder, 60/62%	Ton lots. £19 .. 10 £19 10s. 5 £20 .. 2 £20 10s. 1 F.o.b. or f.o.r. London, 1-cwt. iron drums incl'd.
Sod. Chlorate	3d. per lb. Demand not quite so brisk with better supplies.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide, conc. ..	£15 conc. solid carr. paid. Better demand.
Sod. Sulphite—Pea Crystals	Ton lots. £17 .. 2 £17 10s. 1 1-cwt. wooden kegs included.

WOOD DISTILLATION PRODUCTS

Acetate of Lime Brown	£10 per ton d/d.
,, ,, Grey ..	£20 per ton d/d.
Acetate of Lime Liquor	9d. per gall., 32° Tw.
Iron Liquor	1s. 6d. per gall., 32° Tw. 1s. 2d. per gall., 24° Tw.
Red Liquor	1s. 3d. per gall., 14/15° Tw.
Wood Creosote	2s. 6d. per gall., unrefined. Lower prices, however, are asked in some quarters.

Wood Naphtha—	
Miscible	6s. 6d. per gall., 60% O.P.
Solvent	5s. per gall., 40% O.P.
Wood Tar	£5 per ton d/d.
Brown Sugar of Lead	£39 per ton d/d.

TAR PRODUCTS

Acid Carbolic, crystals	1s. 7d.-1s. 8d. per lb. Practically no change. Market well maintained for next two or three months.
,, ,, crude 60's	4s.-4s. 4d. Demand good. Business still being done at lower figure, but higher prices spoken of in some quarters.
Acid Cresylic, 97/99	1s. 11d.-2s. 3d. Fair enquiries for forward delivery.
,, ,, pale 95%	1s. 10d.-2s. 2d. Moderate enquiry.
,, ,, dark	1s. 6d.-1s. 11d. Fair demand.
Anthracene Paste, 40%	4d. per unit per cwt. Price still nominal. No business.
Anthracene Oil—	
Strained	9¾d.-11d. gall. Fair enquiries.
Unstrained	9d. per gall.
Benzole, crude, 65's	1s. 1d. per gall.
Benzole, standard motor	1s. 6½d.-1s. 8d. per gall.
Benzole, pure	2s.-2s. 3d. per gall.
Toluole, 90%	1s. 9d.-1s. 11d. per gall. Little demand.
Toluole, Pure	2s. 2d.-2s. 6d. per gall. Market firm.
Xylol	3s. 3d. per gall.
Creosote—	
Cresylic, 20/24%	11d.-1s. 1d. Prices still steady.
Middle Oil	8¾d.-9½d. per gall. Good demand.
Heavy	
Standard specification	
Naphtha, crude	9d.-9¼d. per gall.
,, Solvent 90/160	1s. 7d.-1s. 9d. Very little business doing.
,, Solvent 90/190	1s. 6½d.-1s. 7½d. Market still steady.
Naphthalene—	
Crude, drained Creosote salts	£7-£9. Good demand, market firm.
Crude, whizzed or hot pressed	£11-£12. Numerous enquiries for forward delivery.
Pitch, medium soft	185s.-200s. per ton. Market active.
Pyridine, 90/140	11s.-12s.
,, heavy	8s.-9s. per gall. Price still nominal—no business.

INTERMEDIATES AND DYES

Acetic Anhydride	1s. 5d. per lb.
Acid H.	5s. lb. 100% basis d/d.
Acid Naphthionic	2s. 7½d. lb. ,, ,, ,,
Acid Neville & Winther	6s. lb. ,, ,, ,,
Acid Sulphanilic	1s. 6d. lb. ,, ,, ,,
Aluminium Chloride anhydrous	1s. per lb. d/d.
Aniline Oil & Salts	9½d. lb. naked at works.
Antimony Pentachloride	1s. 1d. lb.
Benzidine Base	6s. 6d. lb. 100% basis.
Benzyl Chloride	1s. 4½d. ,, ,, ,,
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. lb. 100% basis.
p-Dichlorbenzol	£55 per ton.
Dinitrobenzene	11d.-1s. lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrophenol	£140 per ton.
Dinitrotoluene 48/50	8d.-9d. naked at works.
66/68	1s. 2d.-1s. 3d. naked at works.
Diphenylamine	3s. 2d. lb. d/d.
Dichloraniline	2s. 2d. lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. lb. d/d. packages extra.
Metanitraniline	5s. 6d. lb. d/d.
Monochlorbenzol	£70 per ton.
α-Naphthol	2s. 9d. lb.
β-Naphthol	1s. 1d. lb. d/d.
α-Naphthylamine	1s. 6½d. lb. d/d.
β-Naphthylamine	4s. lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	7d.-8d. per lb.
Nitronaphthalene	1s. lb. d/d.
o-Nitrochlorbenzol	2s. lb. 100% basis d/d.
p-Nitrophenol	1s. 9d. lb. 100% basis.
p-Nitro-*o*-amidophenol	4s. 6d. lb. 100% basis.
m-Phenylene Diamine	5s. 6d. lb. d/d.
p- ,, ,,	12s. 6d. 100% basis d/d.
Sod. Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. lb. d/d.
m-Toluylene Diamine	5s. lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Prices in this Section show a strong upward tendency. With regard to Tartaric Acid products it is generally recognised that the prices that have been prevailing for some time past have been below the cost of production. There is no doubt that the market has been depressed by stocks carried by speculators and others who bought largely during the demand that was created by the short spell of hot weather last year. The sudden cessation of the warm period caused a slackening in demand, with the consequence that there were large accumulations of Acid from the Continent, which had been bought for forward delivery. For financial reasons, these stocks were thrown on the market at prices which must, in many cases, have represented a loss to importers. Similarly, in order to finance themselves by selling, Continental makers were compelled to bring down their prices to the level thus created. Stocks here are, to a great extent, now liquidated, also demand is increasing hence the upward tendency in price.

Acid Acetic 80%	£52 10s. Position firm.
Acid Acetyl Salicylic	2s. 11d.-to 3s. 3d. per lb. Now quoted on a firmer market. Supplies restricted.
Acid Benzoic	2s. 3d. per lb. Steady and in good demand.
Acid Boric	Unchanged.
Acid Citric	1s. 8½d. per lb., less 5%. Market steady.
Acid Gallic	3s. per lb. for 2-cwt. lots. 3s. 3d. per lb. for 56 lb. lots.
Acid Pyrogallic, cryst.	5s. 9d. per lb. Price advanced.
Acid Salicylic	2s.-2s. 6d. per lb. Very firm. Several makers cannot book further orders for some time.
Acid Tannic	3s. 3d. per lb. is the present limit.

Acid Tartaric	1s. 2¾d. less 5%. Demand still increasing. Spot supplies reported to be short. It is stated that some Italian makers have withdrawn from the market, in view of the anticipated further rise in price to a figure that will be more compatible with the cost of production.
Acetanilide	1s. 6d. per lb. Unchanged owing to lack of any considerable demand.
Ammon. Benzoate	3s. per lb. This price will soon have to be advanced in common with other benzoates.
,, Carbonate, B.P.	£37 10s. per ton. nett.
Atropine Sulphate	12s. 6d. oz. Steady.
Barbitone	14s.-17s. 6d. per lb. Very much advanced. Some holders are asking still higher prices.
Benzonaphthol	3s. 3d. per lb. Still further reduced.
Bismuth Salts	Unchanged. Good steady market.
Bromides	All very firm. Prices on the Continent continue to advance.
Calcium Lactate	2s. 3d. per lb. with prices hardening upwards.
Chloral Hydrate	4s. 3d. per lb.
Chloroform	2s.-2s. 3d. per lb.
Creosote Carbonate	10s. per lb.
Formaldehyde 40%	£88 to £90 per ton.
Guaiacol Carbonate	7s. 6d.-8s. 6d. per lb. now quoted in view of more demand having arisen.
Hexamine	4s. 3d. per lb., with very much higher rates being quoted from Germany.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	3s. 3d.-3s. 6d. per lb.
Iron Ammon. Citrate	2s. 5d. per lb. for 1-cwt. lots.
Iron Perchloride	£20 to £22 per ton.
Magnesium Carbonate Light comml.	£38 per ton.
Magnesium Oxide—Light comml.	£85 per ton.
Heavy comml.	£28 per ton.
Menthol	32s. for original cases. Smaller quantities 33s. per lb.
Methyl Salicylate	2s. 6d.-2s. 8d. per lb. in glass containers.
,, Sulphonal	13s. 6d. per lb. now quoted.
Mercurials	Unchanged but still very firm
Paraformaldehyde	3s. 9d. per lb.
Paraldehyde	1s. 6d.-1s. 8d. per lb.
Phenacetin	6s. 6d. per lb. is now quoted being an appreciable advance on previous rates.
Phenazone	7s. per lb., still fully maintained.
Phenolphthalein	5s. per lb. firming up again.
Potass. Bitartrate 99/100% (Cream of Tartar)	95s.-98s. per cwt. less 2½% demand good.
Potass. Ferricyanide	4s. per lb.
Potass. Iodide	15s. 8d. per lb. for cwt. lots. Good steady demand.
Potass. Permanganate	10d. per lb. is now the minimum price for quantity.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz.
Resorcin	5s. per lb.
Salol	2s. 6d.-3s. 3d. per lb. now quoted.
Silver Proteinate	9s. 6d.-10s. per lb.
Sod. Benzoate	2s. 3d. per lb., with greatly increased quotation from Germany.
Sod. Citrate	U.S.P. quality 2s. 2d. for cwt. lots.
Sod. Hyposulphite, Photographic	£14 15s. for 5-ton lots.
Sod. Potass. Tartrate (Rochelle Salt)	80s.-82s. cwt. Poor demand.
Sod. Salicylate	2s. 6d. per lb. for powder, 2s. 7d. for crystal is now quoted. Makers are mostly fully sold for the next few weeks.
Sod. Sulphite Anhydrous	£27 10s.-£28 10s. per ton according for quantity, f.o.r. London drums included.
Sulphonal	13s. per lb. is the present value.
Tartar Emetic	1s. 4d. per lb. Unchanged.
Thymol	19s. per lb. for good white crystals. Lower prices would be accepted for quantity.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	12s. ,, ,,
Amyl Acetate	2s. 6d. ,, ,,
Amyl Butyrate	8s. ,, ,,
Amyl Salicylate	3s. 6d. ,, ,,
Anethol (melting point 21/22°C.)	4s. 3d. ,, ,,
Benzyl Acetate from chlorine-free Benzyl Alcohol	3s. ,, ,,
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehyde free from Chlorine	3s. ,, ,,
Benzyl Benzoate, 19.5°C.	3s. ,, ,,
Cinnamic Aldehyde—98/100% Natural	14s. 9d. ,, ,,
Coumarin	15s. ,, ,,
Citronellol	22s. 6d. ,, ,,
Citral, 100%	9s. 6d. ,, ,,
Ethyl Cinnamate	18s. 6d. ,, ,,
Ethyl Phthalate	4s. 3d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa)	30s. ,, ,,
Geraniol	5s. 6d.-12s. 6d. per lb.
Heliotropine	7s. 6d. per lb.
Iso Eugenol	17s. ,, ,,
Linalol ex Bois de Rose	21s. ,, ,,
Linalyl Acetate	22s. 6d. ,, ,,
Methyl Benzoate	8s. 6d. ,, ,,
Musk Ketone	35s. ,, ,,
Musk Xylol	9s. ,, ,,
Phenyl Ethyl Acetate	10s. ,, ,,
Phenyl Ethyl Alcohol	17s. 6d. ,, ,,
Rhodinol	45s. ,, ,,
Terpineol	3s. 1d. ,, ,,
Vanillin	24s. ,, ,,

ESSENTIAL OILS

Almond Oil, foreign, S.A.P.	13s. 6d.-16s. per lb.
Anise Oil	2s.-2s. 1d. per lb. spot, 1s. 10½d. c.i.f. forward. Very quiet indeed.
Bergamot Oil	12s. 6d. per lb. spot. Will probably advance with the improvement in the lira.
Bourbon Geranium Oil	28s. per lb. spot. Substantial grounds for the advance difficult to find. Will probably decline when new crop comes to hand.
Camphor Oil, White	82s. 6d. per cwt. Quiet.
Cananga Oil, Java	9s.-10s. 6d. per lb. Quiet.
Cinnamon Oil, leaf, Ceylon	4d.-4½d. per oz.
Cassia Oil	8s. 6d. per lb. spot, 8s. c.i.f. forward. This is likely to go dearer.
Citronella Oil—	
Java	3s. 10d.-4s. 1d. per lb. Very firm.
Ceylon	3s. 3d. per lb. Very firm.
Clove Oil	7s. 9d.-8s. 6d. per lb. Quotations vary daily owing to fluctuations of the spice.
Eucalyptus Oil	1s. 6d.-1s. 9d. per lb. Steady but not much doing.
Lavender Oil—	
Mont Blanc	12s. 6d.-13s. per lb. for high grade oil. Expected to go dearer.
Lemon Oil, spot	3s. per lb., 3s. c.i.f. forward.
Lemongrass Oil	2⅝d. per oz., about the same forward.
Orange Oil, Sweet, spot	10s. 6d. per lb. Distinctly a good market.
Otto or Rose Oil	20s.-32s. per oz., according to quality. A large quantity of very inferior otto offering.
Palma Rosa Oil	17s. per lb. Steady.
Peppermint Oil—	
English	70s.-80s. Quiet.
Wayne County	13s.-13s. 6d. spot, easier forward.
Japanese	6s. 6d.-6s. 9d. per lb.
Petitgrain Oil, Paraguay	7s. per lb. Flat.

TRADE NOTES

Amalgamation of Fertiliser Companies in Japan

H.M. Commercial Councillor at Yokahama has forwarded a report which states that the following three fertiliser companies have amalgamated:—The Japan Artificial Fertiliser Co. (Dai Nihon Jinzo Hiryo Kabushiki Kaisha); the Eastern Acid and Alkali Co (Kanto Sanso K.K.); and the Japan Chemical Fertiliser Co. (Nihon Kagaku Hiryo K.K). The question of the amalgamation of fertiliser companies has frequently been to the fore since the slump of 1920, and the continued lack of market and the vital necessity of lowering the cost of production has made such a step inevitable. As a result of the amalgamation, the two last-named companies will be dissolved, and the Japan Artificial Fertiliser Co. will remain with its capital increased from 14.300,000 yen to 23,400,000 yen.—(*Official.*)

Capital Increases of German Chemical Firms

The following is a list showing the extent to which the capital of some of the most important German Chemical firms has recently been increased:—

	Million marks From	Million marks To
Verein für chemische Industrie Mainz, Frankfurt a. M.	6·5	28·0
Rosol-Werk Magnetine A.-G., chemische Fabriken	9·7	10·0
Bayerische Stickstoffwerke A.-G., Munchen	70·0	100·0
Consolidierte Alkaliwerke Westeregeln	31·5	75·5
Olea-Werke, A.-G. für Mineralöl-Industrie	48·0	60·0
Norddeutsche Sprengstoffwerke A.-G., Hamburg.	4·0	7·0
Mitteldentsche Stickstoffwerke A.-G., Berlin	250·0	500·0
Max Hahn, Chemische Fabrik A.-G., Berlin	6·0	11·0
Norddentsche Acetylen- und Sauerstoffwerke A.-G., Hamburg	6·75	10·0
Gebr. Meyer, chem.-techn. Fabrik A.-G., Hannover	9·0	15·0
Alberdingk-Oelwerke A.-G., Uerdingen	6·0	12·0
Concordia, Chemische Fabrik auf Aktien, Leopoldshall	2·5	6·8
Aktiengesellschaft fur Bergbau- Blei- und Zinkfabrikation in Stolberg und in Westfalen	36·0	72·2
Chem.-pharmaz. Werke Mayer-Alapin A.-G., Frankfurt a. M.	8·6	12·2
I. D. Riedel A.-G., Berlin	90·0	150·0
A. F. Heyde, Chemische Fabrik A.-G., Berlin	7·5	12·0
Lingner-Werke A. G., Dresden	24·0	36·0

These and other increases represent an aggregate augmentation in capital from 675,950,000 marks to 1,220,637,600 marks. Among recent establishments of new chemical firms, the following may be mentioned, the capital being given in parentheses in millions of marks:—Verein für Zellstoff-Industrie A.-G., Berlin (40); Bayrische Farben- und Lackindustrie A.-G., Munchen (20); Pharmazeutisches Werk Pharmasaar A.-G., Saarbrucken (20); Roth and Paschkis A.-G., Stuttgart (40).—(*Chem. Ind., Feb.* 19, 1923.)

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, APRIL 6, 1923 No. 14

EDITORIAL

THE interest, which the nation as a whole ought to take in chemistry, is well illustrated by the Report of the Home Office Departmental Committee on the use of Lead Paints published to-day. Of the seven members of the Committee, one, Dr. Alexander Scott, F.R.S., is well known as a chemist, and two or three others have some considerable acquaintance with the science. Several of the witnesses who gave evidence before the Committee are chemists, and most of these have contributed articles to this Journal. The whole problem, though not strictly a chemical one, involves chemistry in every aspect; the solubility of various lead compounds in dilute acids including gastric juices, the causes of the deterioration of pigments in the atmosphere of our manufacturing towns and the effects of turpentine and other volatile thinners are chemical phenomena which had to be investigated by the Committee. The durability of the paint on Government buildings was investigated by the Chief Government Chemist, and the analyses he made of various paints scraped from doors and windows are published with the Report. Chemists must be pleased that an important set of problems should be studied by a body of men, a large proportion of whom have some scientific knowledge, and studied in a manner which recognises the principles which underlie modern civilisation. The work of this Committee and the Report it has published might well become models which many other committees might strive to emulate.

* * *

The Committee has accepted the principle that lead poisoning is caused by dust and has rejected, as chemists had already rejected, the suggestion that it was caused by some volatile lead vapour or emanation. The idea of a lead emanation from painted surfaces seems to have received some support from black stains on filter papers proved to contain traces of copper due to the wire gauze on which the filter papers were dried. Modern chemical tests are frequently very sensitive, and colour effects due to minute traces of metals, alkaloids and other bodies are not always trusted quite so much as tests which involve larger amounts of ponderable matter. The report recommends the abolition of the dry rubbing down of paint, a fruitful source of dust. Dust is bad for human beings and probably in the damp climate of England we are less able to endure it than are the inhabitants of other countries. Washing down the dust from the throat is a time-honoured practice, and indeed some, believing that prevention is better than cure, practise thus before the dust has largely accumulated; but to keep the dust out of the atmosphere is a still safer expedient. Wet rubbing down of paint reduces the dust to about five per cent. of that present during dry rubbing down, the difference between safety and danger, and we wonder in how many chemical operations similar precautions would be helpful.

* * *

Those who manufacture chemical compounds and those who use them day after day have a duty to perform, to avoid waste, waste of human life and energy, waste of time, waste of material. During the last four or five days many of us have been able to exchange the smoke of a town for "an ampler ether, a diviner air," and though we cannot all afford to journey to those climes "where falls not hail, or rain or any snow, nor ever wind blows loudly," we can all do something towards making use of modern science in mitigating the adulteration of the air we breathe. When we compare the atmosphere of Liége with that of Sheffield or that of some of the French manufacturing towns with that of Widnes, we realise what a task lies before us. But if we work at the problem in the manner and with the care of the Home Office Departmental Committee we may do much. Three-quarters of the dust and fumes in our factories and workshops and of the smoke in our towns could be avoided without any very revolutionary methods. Meanwhile the Committee's Report seems to be of such interest that we will shortly publish a summary of it.

* * *

If we are to take our national receipts and expenditure as evidence—and why not?—we are making slow yet steady progress towards that prosperity which we covet and deserve. We deserve it because we are facing our huge indebtedness in the only practical way—cutting down our spending so as to leave a margin as recommended by the late Mr. Micawber, whose financial theory was better than his practice. Grievous as is our taxation, it has diminished and will continue to diminish, and this enables our home trade to revive somewhat. There are many indications which point to a steady recovery in trade here, and the outlook is distinctly more encouraging. Our foreign trade will also improve. The ordinary expendidure of France is now met by taxation, and her extraordinary expenditure in repairing the devastated areas has been much curtailed. We may shortly hope for four or five prosperous foreign countries. As for those who make up their minds to live within their income, even if they have to borrow money to do it, such a policy cannot long continue; already there are symptoms of barter, or trading by means of obligations secured by material assets, in Germany, and before many months the nearly worthless marks of that country may be discarded and a stable currency founded on a new basis may be established. A new chemistry there may be, but the principles of political economy have been settled as the result of innumerable experiments conducted during countless centuries.

* * *

Prof. Stanley Allen, who contributes to this number an article on the Structure of the Atom, has provided an interesting account of the growth of our ideas from the early days of Democritus to the New Chemistry which we referred to in a recent editorial. The quotations he makes from the writings of Democritus are in some cases out of date, but in others singularly in accordance with modern views. This is true also of the verse of Lucretius and of many another ancient writer. The ancient Greeks knew that the square root of 2 could not be expressed by any vulgar fraction, and this is evidence of considerable reasoning on a rather abstruse point of mathematics. On the other hand, the facts upon which chemistry is founded were almost wholly unknown to them, and great as are the virtues of imagination, a superstructure founded on this as a foundation becomes insecure.

THE STRUCTURE OF THE ATOM

By **H. STANLEY ALLEN, M.A., D.Sc.**

Professor of Natural Philosophy in the University of St. Andrews

§ 1. The Development of the Atomic Theory

Greek philosophers, some twenty-five centuries ago, were teaching that changeful matter is made up of indestructible particles in constant motion. Amongst the principles of Democritus (420 B.C.), as quoted by Tyndall, we find the following:—

"The only existing things are the atoms and empty space; all else is mere opinion.

"The atoms are infinite in number and infinitely various in form; they strike together and the lateral motions and whirlings which thus arise are the beginnings of worlds.

"The varieties of all things depend upon the varieties of their atoms, in number, size, and aggregation."

Thus far we have statements which, with some slight modifications, might be accepted by the majority of physicists or chemists of the present day. We might, however, find some difficulty in subscribing to the further principle:—

"The soul consists of fine, smooth, round atoms like those of fire. These are the most mobile of all. They interpenetrate the whole body and in their motions the phenomena of life arise."

Boscovich, author of *A Theory of Natural Philosophy* (1763), is sometimes claimed as the father of modern atomic theory. He showed "with admirable clearness how many diverse phenomena in mechanics and even in other branches of physics can be explained in a natural qualitative way on his hypothesis that matter consists of discrete points accelerated towards each other by a perfectly definite law of suitable form. But from the modern point of view his work in this connexion is scarcely more interesting than the earlier work of Daniel Bernoulli, or the still earlier ideas of Hooke." *

The work of Dalton and his successors during the first half of the nineteenth century gave precise and quantitative form to the early speculations of the Greeks. Instead of an infinite variety of atoms it was found that only seventy varieties, constituting the "elements" of the chemist, were necessary to build up by means of their different combinations and groupings the substances of the material world. It is not overstating the case to say that the atomic hypothesis put forward by Dalton has within the last twenty-five years been proved to give an extremely close representation of the actual state of affairs. Even Wilhelm Ostwald, the distinguished chemist and philosopher, who until recently, withheld his allegiance from the atomic theory, has now avowed his belief in the discrete or grained structure of matter.

---

* "Nature," vol. 110, p. 870, 1922.

"The isolation and counting of gaseous ions on the one hand . . . and on the other the agreement of the Brownian movements with the requirements of the kinetic hypothesis . . . justify the most cautious scientist in now speaking of the experimental proof of the atomic theory of matter. The atomic hypothesis is thus raised to the position of a scientifically well-founded theory."

§ 2. The Atomic Theory of Electricity

If, then, we accept without hesitation an atomic theory of ordinary matter, what are we to say of electricity? It was clearly recognised by the great master of electrical science, Michael Faraday, that the experimental facts which he discovered with regard to the decomposition of chemical compounds by the passage of an electric current through a solution necessitated a similar view with regard to electric charges. Faraday wrote in 1834: "If we adopt the atomic theory or phraseology, then the atoms of bodies which are equivalent to each other in their ordinary chemical action, have equal quantities of electricity naturally associated with them." The charge carried by a univalent ion is independent of the nature of that ion. A divalent ion carries exactly twice and a trivalent ion three times this quantity. Faraday's disciple in electrical theory, Clerk Maxwell, suggested that the constant molecular charge (revealed by Faraday's experiments) might be called one molecule of electricity, but he regarded this as a provisional hypothesis not likely to be retained when we come to understand the true nature of electrolysis. It is not a little remarkable that in 1871 Weber pictured the elementary magnets, which Ampère had imagined fifty years earlier, as due to the rotation of light, positive charges about massive negative ones. "The two unlike particles in the condition described constitute then an Amperian molecular current." This suggestion corresponds closely to our modern ideas, save that the *rôle* of the positive and negative particles must be interchanged. In 1874 Johnstone Stoney gave a clear statement of the atomic theory of electricity, and in 1891 suggested the term "electron" to designate the "natural unit of electricity" or the electric atom. It was largely the experiments of J. J. Thomson and his fellow-workers at the Cavendish Laboratory at Cambridge from 1897 onwards, which furnished convincing evidence of the atomic constitution of electricity, and determined the charge carried by the electron, or "corpuscle" as J. J. Thomson termed the negatively electrified unit found, for example, in the "cathode rays" of a Crookes tube.

To the physicist the electron is just as "real"—no more and no less—as is the atom to the chemist. Perhaps there is no fact which reveals more clearly the power of modern physical methods than our ability to detect and examine the effects produced by a *single* atomic projectile or a *single* electron. If we cannot *see* an atom or an electron we can at least render its track visible, provided only it is moving with sufficiently great velocity. The most striking results of this kind are those obtained by C. T. R. Wilson, at Cambridge, who caused drops of water to condense on the ions produced along the track of the swiftly moving particle.

§ 3. Atomic and Molecular Numbers

The *atomic weight* of an element has long held a proud position in the chemical world, but at the present time still greater importance must be attached to the *atomic number*. This number may be defined as the integer which determines the position of an element in the Periodic Classification. The conception of such a characteristic number originated in the work of M. de Chancourtois (1862-3), who stated definitely that: "The properties of the bodies (elements) are the properties of number," and of Newlands (1863-5). The latter arranged the elements in the ascending order of their atomic weights, numbering them from 1 to 56. According to his "Law of Octaves":—

"The numbers of analogous elements, when not consecutive, differ by 7 or some multiple of 7."

Newlands admitted that it might be necessary to alter the number 7 to some higher figure, if other elements should be discovered.

One critic, whose cynicism was greater than his foresight, asked Newlands, "whether he had ever examined the elements according to the order of their initial letters?"

The chemical evidence for an atomic number has in recent times received overwhelming support from the physical side; van den Broek first made the fruitful suggestion that the atomic number represented the number, N, of negative electrons which, together with an equal number of unit positive charges, constituted an electrically neutral atom.

The use of the chemical balance led to the development of the atomic theory, and so to the determination of atomic weights. The gold leaf electroscope, employed in connexion with X-rays and Becquerel rays, may be said to have fixed the atomic numbers. In this connection the name of H. G. J. Moseley, killed, alas! in Gallipoli, will ever be remembered. By examining the X-ray spectrum of a large number of elements he was able to show that a definite whole number must be associated with each element. This integer varies by unity from one element to the next. The values so determined are, however, only *relative*. It was assumed that the characteristic integer for aluminium was 13, and the numbers for elements of greater atomic weight were assigned on this basis. Evidence has been accumulating that the choice made by Moseley was correct; in particular the work of Prof. Barkla on scattered X-rays indicates 6 electrons per atom of carbon, 7 for nitrogen, 8 for oxygen, 16 for sulphur and 1 only for hydrogen. Thus the atomic numbers for the first few elements run

H, 1
He, 2; Li, 3; Be, 4; B, 5; C, 6; N, 7; O, 8; F, 9
Ne, 10; Na, 11; Mg, 12; Al, 13 . . . .

In the case of the elements of high atomic weight at the other end of the Periodic Table, mention must be made of the important work carried out by Prof. Soddy and other chemists which has done so much to explain the relative positions of the radioactive elements through the discovery of "isotopes," *i.e.*, substances differing in atomic weight but having identical chemical properties.

If a Periodic Table of the elements be prepared with the atomic numbers inserted in place of the atomic weight, it is found, as I pointed out in 1918,* that the numbers for corresponding elements frequently differ by 8, or a multiple of 8, in general agreement with the prediction of Newlands. Owing to the presence of three elements instead of a single element in Group VIII., the difference is in some cases increased by 2 units, giving the figure 10 in place of 8, or 18 in place of 16. At the same time I pointed out the significance of what I called the "molecular number" which represents the total number of unit positive charges or the corresponding number of negative electrons in a neutral molecule. Here, too, the "Rule of Eight" is applicable.

§ 4. THE ARRANGEMENT OF THE ELECTRONS IN SPACE

The Theory of Lewis and Langmuir

So far we have been concerned with the *arithmetic* of the electrons. We pass now to the next step in the development of the electron theory of the constitution of atoms and molecules—namely, that of assigning a definite spatial configuration to the electronic system. From arithmetic we proceed to *geometry*. A most interesting attempt of this kind has been made by Lewis and Langmuir.

The facts of stereochemistry make it clear that a three-dimensional geometry is required.

The inert gases are the most stable of the elements. We infer that in these the groupings or configurations of the electrons are the most stable possible. We may go further and say that in these gases the groupings are complete, whilst in other elements the groupings are incomplete, so that the activity of such elements is attributed to the tendency "to conform as nearly as possible to the complete and therefore inert elements."

Consider, then, the atomic numbers of the inert gases. These form the series :—
He, 2 ; Ne, 10 ; A, 18 ; Kr, 36 ; Xe, 54 ; Nt, 86 ;
These are all *even* numbers and Rydberg has pointed out that they form the series :—

$$N=2\ (1+2^2+2^2+3^2+3^2+4^2+)$$

From a consideration of this equation and of the principles of symmetry Langmuir developed a theory as to the geometrical arrangement of the electrons in these atoms. He supposes the electrons are distributed through a series of concentric spherical shells; the effective radii of the different shells stand in the ratio 1 : 2 : 3 : 4, and the effective surfaces are in the ratio $1 : 2^2 : 3^2 : 4^2$.

The most stable element of all is *helium*. The nucleus has a positive charge of 2, and the atom has two electrons. We imagine the nucleus in the centre, and each electron in one half of a complete shell (like a walnut shell) surrounding it. Neither electron trespasses upon the territory of the other. It is not necessary to regard the electrons as stationary, but we may for simplicity consider each as occupying its average position.

In the helium atom we have a complete satisfaction of the positive and negative charges, with practically no external field. The grouping in pairs about a positive charge may be regarded as the first electronic ideal.

The next most stable element is *neon*, N=10. It is assumed that, like helium, 2 electrons are near the nucleus. The remaining 8 arrange themselves in a second shell, four in either hemisphere. This arrangement of 8 electrons may be called an *octet*. Next to the balanced pair of electrons the octet is the most stable grouping.

Argon has N=18. There are 8 more electrons to dispose of, and Langmuir imagines that each cell of the second shell now contains 2 electrons instead of 1 as in neon.

In *krypton*, N=36, it is necessary to employ a third shell containing 18 electrons, 9 in each hemisphere. Xenon, N=54, is similar to krypton, except that each cell in the outer shell contains 2 electrons in place of 1.

Niton, N=86, necessitates a fourth shell containing 32 electrons, 16 in each hemisphere.

The stability and inactivity of these elements is attributed to the electrons being placed in the most ideal position for the production of a balanced system, so that there is a minimum field of external force.

The key to all chemical combination is found in the striving of all elements to become as nearly as possible like the fixed gases.

According to Lewis chemical compounds may be divided broadly into two types—*polar* and *non-polar*. As an example of the former type we may take lithium fluoride. The single electron in the outer shell of the lithium atom may be supposed to pass to the outer shell of the fluorine atom so as to complete the octet. We then have a positively charged lithium ion and a negatively charged fluorine ion, and the electrostatic attraction between these ions results in the formation of a molecule of lithium fluoride (LiF). This view is in harmony with the results obtained by Sir William Bragg and his son, Professor W. L. Bragg, by X-ray analysis of crystals of rock salt (NaCl) or sylvine (KCl).

---

* Journal of the Chemical Society, vol. 113, p. 389, 1918.

In chemical compounds of the second type no ionisation need be involved, and the chemical bonds or "valencies," *i.e.* the couplings between the atoms, are determined by pairs of electrons. One electron held in common never holds two atoms together. Two atoms held together by a single valency bond hold two electrons in common. This is illustrated in the case of the fluorine molecule.

At first one may be inclined to regard Langmuir's postulates as too artificial to form the basis of a satisfactory theory, but a closer examination serves to show that the essential points are comparatively simple. No one who heard the theory expounded by Langmuir in its simplified form at the Edinburgh meeting (1921) of the British Association for the Advancement of Science could fail to admire the brilliant way in which so large a number of chemical facts might be co-ordinated. It is not necessary to regard the arrangement of the electrons in the Lewis-Langmuir atom in too definite a manner; indeed, the geometrical representation may be looked upon as essentially schematic.

§ 5. THE MECHANICS OF THE ATOM

But even when the spatial distribution of the electrons has been determined, a third step still remains to be taken. It is necessary to consider the mechanics of the system, or at least such modified mechanics as are suggested in the modern theory of Quanta.

The electrical theory of the constitution of matter in many respects resembles Prout's hypothesis, according to which all chemical elements are built up of the same primordial stuff. But in the electrical theory we are left with the dualism of positive and negative electricity. Various models based on this theory have been suggested for the structure of the atom, but all agree in postulating the combination of a definite number of negative electrons with an equal number of unit positive charges.

Lord Kelvin pictured the positive electricity as distributed uniformly throughout a sphere of atomic radius with the negative electrons scattered inside the sphere. The possible arrangements of the electrons in space have been discussed by Sir J. J. Thomson, who has obtained very suggestive results as to the grouping of the electrons and has shown how the facts exhibited in Mendeléef's periodic classification of the elements may be explained, or at least illustrated, by the recurrent arrangements of rings of electrons.

In 1904 Nagaoka discussed an atomic model, which may be termed a Saturnian atom, with an attracting centre and a large number of equal particles, repelling one another inversely as the square of the distance, moving round the circumference of a circle. Very similar is the "nucleus atom" developed by Rutherford in 1911. In this model the positive charge is concentrated in a nucleus of extremely small dimensions, but containing practically the whole mass of the atom, whilst the electrons are arranged round about the nucleus, perhaps moving in orbits or in certain definite rings. Here, however, we are faced by a serious difficulty. According to classical dynamics such a system must ultimately come to rest through exhaustion of energy by radiation. To meet this and other difficulties Prof. Niels Bohr has boldly discarded the Newtonian laws and substituted a new set of principles embodied in what is known as the Quantum Theory.

In the simple case of the hydrogen atom Bohr supposes that the single electron is circling round the positive nucleus in an orbit which may be described as a one-quantum orbit, a two-quantum orbit, and so on. Radiation occurs when the electron in some unexplained manner jumps from one possible orbit to another of greater stability. In helium in its normal state the two electrons are both moving in one quantum orbits, the planes of the orbits being inclined to one another. The arrangements of the electrons in the atoms of the inert gases, according to the theories of Langmuir and of Bohr, are given in the following table. The small subscript figures indicate the kind of orbit in which Bohr supposes the electrons to be moving, whether a one-quantum orbit, a two-quantum orbit, or so on.

Langmuir	*Element*	*Bohr*
2	Helium	2_1
2 8	Neon	2_1 8_2
2 8 8	Argon	2_1 8_1 8_2
2 8 8 18	Krypton	2_1 8_2 18_3 8_2
2 8 8 18 18	Xenon	2_1 8_2 18_3 18_3 8_2
2 8 8 18 18 32	Niton	2_1 8_2 18_3 32_4 18_3 8_2

It will be noticed that whilst in Langmuir's theory the number of electrons in the outer shell increases up to 32, in Bohr's theory the outermost electrons never exceed eight in number.

In 1914–15 I suggested that Rutherford's model atom might be modified if it were supposed that the positive part of the atom were endowed with a magnetic moment, so that we should obtain an atomic model with a magnetic core.

An interesting attempt to construct an atomic model on mechanistic principles has been made by A. L. Parson, who supposed the electron endowed with a magnetic moment. A simple way of effecting this is to distribute the charge of the electron round a circular ring, like an anchor ring, which spins about its axis. Such a spinning "ring electron" will be threaded by lines of magnetic induction and will possess a magnetic moment. It may conveniently be termed a "magneton," and Parson's paper published by the Smithsonian Institution in 1915 bears the title, "A Magneton Theory of the Structure of the Atom." The theory as there presented suffers to some extent from the fact that it is based on the Kelvin and Thomson idea of a uniform sphere of positive electricity, although Parson himself recognised that this part of the theory was purely formal, and it suffers also because the number of magnetons assumed in the atom does not agree with the atomic number of Moseley, which is now generally accepted as correct. The theory gives a simple representation of the hydrogen atom and of the hydrogen molecule. A prominent feature of Parson's theory is the group of 8 magnetons, which forms a system of low magnetic energy, and therefore of considerable stability. Parson constructed a working model to illustrate the behaviour of such a group when under the influence of an external magnetic field.

Many of the properties of organic compounds indicate an apparent localisation of the affinities in particular regions of the atoms. Stark attempted to account for this by his theory of valency, but the attempt scarcely bears rigid examination when electrostatic forces only are considered. On the other hand, if the electron acts also as a magneton, the difficulty becomes less serious, for the magnetic attraction may serve to link the atoms together, and provide the force of chemical affinity in non-polar compounds.

To be satisfactory an atomic model must explain the facts of magnetism, for it is now recognised that magnetism is an attribute of the atom or its parts, not of the molecule. This means that the elementary magnet postulated by Weber is to be found in the atom, the "Weber element" being due either to electrons circulating in orbits about a central nucleus, or to the electron itself possessing a magnetic moment and behaving as a magneton. Sir Alfred Ewing has recently revised his original theory of magnetism and has constructed a number of models to represent more accurately the Weber elements and their positions of stability. In some of the models the electron orbits are shown by coils conveying currents, in others the Weber element is represented as a small magnet or a group of small magnets. In one case an octet of magnetic poles can turn from one position of stability to another under the influence of the fixed magnets surrounding it. In these new models a narrow range of stable deflection is secured without excessive stability.

In a most suggestive paper Prof. Whittaker has developed from Sir Alfred Ewing's new model a mechanism for explaining how it comes about that all exchanges between the kinetic energy of electrons and radiant energy conform to the "quantum" condition. Shortly afterwards I pointed out that this mechanism, which may be termed a "magnetic wheel," provides a law of force which renders possible a static atom with electrons occupying fixed positions as pictured by Langmuir.

§ 6. THE STRUCTURE OF THE NUCLEUS

It is possible to refer only in the briefest way to that most interesting problem, the structure of the nucleus itself. For that the nucleus of a heavy atom is complex seems clearly proved by the emission of α and β particles (helium nuclei and negative electrons) from radioactive substances. Further, recent experiments of Sir Ernest Rutherford have shown that on passing rapidly moving α particles through nitrogen gas, particles are projected forward by the impact of the α particles on the nitrogen atoms, which can be identified as charged atoms of hydrogen. Thus it appears that the hydrogen nucleus is a constituent part of the nitrogen atom. Sir Ernest Rutherford suggests the name "proton" for the hydrogen nucleus, and the nucleus of any other atom may be regarded as formed of a certain number of protons bound together by the requisite number of negative electrons. It may be that the protons tend to arrange themselves in groups of three or four.

This return to Prout's hypothesis is supported by the very remarkable work of Dr. Aston on "positive rays." By an ingenious method he has been able, using an instrument which he calls a "mass spectrograph" to determine the atomic weights of the elements, and has shown that, taking oxygen as 16, the masses of the different atoms can be expressed as whole numbers. Thus chlorine, for which chemists had found an atomic weight 35·4, is found to be a mixture of two gases (isotopes) of atomic weight 35 and 37. The only exception to the whole number rule appears to be hydrogen itself, and it may be inferred that the formation of a helium nucleus by the combination of four protons and two electrons is accompanied by the liberation of a considerable amount of energy. It is perhaps idle to speculate on the possibility of utilising such energy, but it has been calculated that the conversion of 1 gram of hydrogen into helium would liberate enough energy to run a 2000 kilowatt motor continuously for more than four days. The fact that the hottest stars, when examined by the spectroscope, are found to contain little but hydrogen, helium and two unknown substances, may be of significance in this connexion. Possibly we are witnessing here the process of building up complex atoms from the simple elements. If that be the case, we have found the missing half of the cosmic cycle of which the opposite process—the breaking up of atoms—is already known to us in the disintegration of the radioactive elements.

THE EXISTENCE OF AMMONIUM HYDROXIDE IN SOLUTION

By PROF. T. S. MOORE

Professor R. M. Caven, in a recent article on "The Basic Strength of Ammonia and Allied Bases" (*Chemistry and Industry*, 1923, p. 164), states that it is "unlikely that in a N/100 solution of ammonia any but a small quantity of undissociated ammonium hydroxide exists," and his chief arguments in favour of this conclusion are:—(*a*) the compound NH_4OH has never been isolated; (*b*) no distinctive and recognisable properties attributable to NH_4OH are shown by aqueous solution of ammonia; (*c*) physical evidence derived from observations on solid ammonium compounds show that "in the series of alkali metals ammonium occupies a very high place near to caesium," so that ammonium hydroxide, if it exists at all, would be a very strong base and therefore practically completely ionised in dilute solution; and finally (*d*) that no information has been furnished as to the proportion of non-ionised ammonium hydroxide present in aqueous solution. The object of this article is to point out the weakness of these arguments and to offer some positive though indirect evidence that a considerable proportion of ammonia in dilute aqueous solution does exist in the form of an ionisable hydroxide.

Purely negative arguments such as those under (*a*) and (*b*) might be advanced against the existence of $(H_2O)_2$, and H_2CO_3 in aqueous solution, yet the indirect evidence for the existence of these compounds is generally thought to outweigh the absence of direct evidence. Such arguments have little weight against the evidence for the existence of ammonium hydroxide mentioned below.

The evidence on which argument (*c*) is based is that the pressure of aqueous vapour in equilibrium with the systems $CuSO_4 \cdot M_2SO_4 \cdot 6H_2O \rightleftarrows CuSO_4 \cdot M_2SO_4 \cdot 2H_2O$ (M=ammonium or univalent metal) at any one temperature, decreases as M travels along the series K, Rb, Tl, NH_4, Cs (Caven and Ferguson, *Chem. Soc. Trans.*, 1922, **121**, 1406); and that the order thus found is confirmed by the morphological and physical properties of the salts of the same radicles (Tutton, *Chem. Soc. Trans.*, 1903, **83**, 1049). The deduction from this evidence is best given in the exact words of the original paper (p. 1413):—"The present results may be supposed to relate directly to the basigenic properties of the metallic radicles concerned since they express the power conferred on the double sulphate molecule of retaining water of crystallisation against the dissociating influence of rising temperature. The inference therefore, is that the corresponding hydroxides stand in the following order of increasing basic strength: KOH, RbOH, TlOH, NH_4OH, CsOH."

No reason is given for thus connecting the power of retaining water of crystallisation with the basigenic properties of the metal, and that these properties are directly connected seems to be an arbitrary assumption. But if we assume such a relation and apply it to the series of double salts $CuSO_4$, M_2SO_4, $2H_2O$, we must conclude that caesium is the least basigenic of the radicles under consideration, for only the caesium compound of this type loses water below 100° C. (*loc. cit.*, p. 1407). Thus the basis of argument is obscure, and it leads to different conclusions when it is applied to the two different series of double salts.

As regards (*d*), a method for investigating the equilibria in solutions of ammonia and amines was published in 1907 (Moore, *Chem. Soc. Trans.*, 91, 1373) and developed and applied in 1912 (Moore and Winmill, *ibid.*, 101, 1635). The method is somewhat complicated and is subject to considerable error, but it is the only one yet published which allows of the determination of the equilibrium constants of the reactions involved. At 25° these constants were found to be:—

$$k_1 = C_{NH_4^{\cdot}} \times C_{OH'} / C_{NH_4OH} = 3{\cdot}41 \times 10^{-3}$$
$$k_2 = C_{NH_4OH} / C_{NH_3} = 1{\cdot}15.$$

(concentration in gm.—equivalents per c.cm.)

These numbers are calculated from, and therefore in agreement with, the electrical conductivity of solutions of ammonia, the partition coefficient of ammonia between water and chloroform, and the heat of neutralisation of ammonia. From them, using Perman's measurements of the partial pressure of ammonia above aqueous solutions (*Chem. Soc. Trans.*, 83, 1174, 1903), the heat of solution of ammonia in water was calculated to be 8460 cals., a value in excellent agreement with 8440 cals. found by Thomsen for the same concentration and temperature.

Calculation from these constants shows that in a N/100 solution roughly 51 per cent. of the ammonia is present as NH_4OH, 45 per cent. as NH_3 or a non-ionisable hydrate, and 4 per cent. as the ammonium ion. If the views put forward by Professor Caven had been correct, the concentration of NH_4OH would have been found very small or zero, k_1 very large or infinity, and k_2 very small or zero.

We have at present no experimental method for distinguishing between the alternative paths by which equilibrium could be reached. The application of the law of mass action to the equations put forward by Professor Caven leads to equilibrium equations identical in form with those derived from the older scheme $NH_3 + H_2O \rightleftarrows NH_4OH \rightleftarrows NH_4^{\cdot} + OH^1$, and the values of the constants involved have been found as already described. The physical significance of these constants—not their numerical values—will of course be different, according to the set of reaction equations used.

In any case there is definite evidence that ammonium hydroxide exists in solution and that it is a weak base.

Royal Holloway College, Surrey

OBSERVATIONS BY "EYE-WITNESS"

The Editor welcomes the comments and expressions of opinion by his contributors, but it must be understood that he does not necessarily agree with them.

The Passing of Sir James Dewar

removes one of the outstanding figures in the scientific world from our midst. He held a peculiar position by reason of his dynamic personality. Others will write of his scientific discoveries, but I prefer to think of his personality as I knew it. I think the leader writer of *The Times* summed up in a sentence what one would like to say:—"He was a great man, vigorous, kindly and combative." I wonder whether anybody else has been described as "kindly and combative," yet that is exactly what he was. To sit in that wonderful drawing-room of his and listen to his talk over the tea-table was a delightful experience. To hear him in his room downstairs pour out his wrath on some misguided individual was to realise how effective the English language can be in the mouth of a master. I recall a third phase, when on a particular occasion during the war, surrounded by nearly the whole Army Council, he demonstrated some of the properties of liquid air. The great ones sat as little children while for an hour they absorbed the information he gave them and only once, and then for a brief moment did the combative spirit break through and he became volcanic. His many kindnesses will be remembered by men all over the world long after his combats are forgotten.

The Development Committee

under the Dyestuffs Act is one of those Committees which you do not hear very much about. I met some of its members in a train in the North of England some weeks ago and again on the Underground in London recently. It appears that the Committee are personally inspecting all the dyestuff factories in the country and are noting the developments which are taking place. I understand that the dyestuff makers' representatives do not visit each other's works, but that Prof. Jocelyn Thorpe and Prof. Morgan, with the representatives of the Board of Trade, War Office and Admiralty and the Technical Advisers to the Committee, are making a very thorough investigation. I am assured that in some respects the amount of development which has taken place has exceeded the Committee's expectations. There are now eighteen firms engaged in the manufacture of dyestuffs, and while 75 per cent. of the total output comes from one firm, I am told that some of the smaller firms are not only doing valuable work in special dyestuffs, but are doing it in such a way as to earn high praise from members of the Committee.

The International Dye Position

is becoming more complicated day by day. The central factor in the problem is the fact that during the War the Allies were all compelled to increase their dyestuff factories to meet the requirements of their colour users. Hence to-day the amount of dyestuff plant in the world is probably as much as 50 per cent. in excess of the world's requirements. This excess of plant will have to be scrapped before prices can be got to a proper economic level. But the conditions vary in the different countries. In Switzerland I believe the plants are written down to practically nothing owing to the profits made during the war. In Germany the same applies and in addition there is the advantage of the exchange. England and America, however, are in the position of having to fight not only the German exchange, but the difficulty of not having sufficient orders to keep their plant running at an economic rate of production. Nevertheless, to supply 80 per cent. of the users' requirements is no mean feat, and although there are no dividends for the British dyemaker I hope he will not give up the fight.

Reparation Dyes

are also a perplexing subject at the moment. In accordance with the Treaty of Versailles the Allies are entitled to take a certain amount of German dyestuffs which they are supposed to require for their own use; there is, however, a grave suspicion at the moment that reparation dyestuffs are being sold at ridiculous prices by some of the Allies. One can quite see that if one of our Allies is in a position in which she knows she is not likely to obtain any cash from Germany but can obtain some dyestuffs, these dyestuffs having cost her nothing she is liable to sell at anything they will fetch. I believe quite a large quantity of German dyestuffs have gone from Italy to America recently and constantly such dyestuffs are finding their way from Belgium to England. This is a matter somebody ought to look into.

Colonel Jos. I. McMullen,

who has just left our shores, is a most interesting personality. He came over here as the representative of the United States on the Royal Commission on Awards to Inventors. I met him several times at various functions. He is one of those people who have gone about the world with their eyes wide open and have acquired an immense amount of information. He gave, however, as much as he received and was one of the most pleasing and efficient representatives who have come over from the States. His knowledge of chemical industry both in America and on the Continent is very wide and during the few months he was over here he managed to find time to have many talks, not only with our statesmen and politicians, but with industrialists as well.

FORTHCOMING EVENTS

Apr. 9. Royal Society of Arts, John Street, Adelphi, W.C. 2, at 8 p.m. "Nitrates from Air": E. K. Scott, M.I.E.E. Also on April 16 and 23.

Apr. 9. The Institution of Rubber Industry, Engineers' Club, Coventry Street, Piccadilly, W. 1. "Rubber Pigments," by Dr. D. F. Twiss.

Apr. 9. Society of Chemical Industry, *London Section*, at the Engineers' Club, Coventry Street, W. 1, at 8 p.m. (1) "The Cod-liver Oil Industry of Newfoundland," by S. S. Zilva and J. C. Drummond. (2) "A Study of the Separation of the Gases formed in the n-Butyl-Alcohol-Acetone Fermentation Process," by E. W. Blair, T. S. Wheeler and J. Reilly.

Apr. 9. The Ceramic Society, the Central School of Science and Technology, Stoke-on-Trent, at 7.30 p.m. "Black and Grey Flints," by A. Heath and A. Leese.

Apr. 10. Society of Chemical Industry, *Birmingham and Midland Section*, the University Buildings, Edmund Street, Birmingham, at 7 p.m. "Some Observations on the Activated Sludge Process," by F. R. O'Shaughnessy, A.R.C.Sc. "Some Studies in Catalytic Hydrogenation," by E. J. Lush, M.A.

Apr. 10. Institute of Metals, *Birmingham Local Section*, the Chamber of Commerce, New Street, Birmingham, at 7 p.m. Annual General Meeting.

Apr. 10. Institute of Metals, *North-East Coast Local Section*, Electrical Engineering Lecture Theatre, Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. Annual General Meeting.

Apr. 11. Society of Chemical Industry, *Newcastle-on-Tyne Section*, The Chemical Lecture Theatre, Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. "Fertilisers and Chemical Industries in relation to the Ruhr Situation and present conditions": Monsieur Braun.

Apr. 12. The Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C. 2, at 6 p.m. "The X-Ray Examination of Materials," by A. G. Warren.

Apr. 12. Society of Chemical Industry, *Ottawa Section*, University Club, Elgin Street, Ottawa, at 8 p.m. "Electrolytic Iron," by R. J. Trail.

Apr. 12. Institute of Metals, *London Local Section*, Institute of Marine Engineers, 85-88, The Minories, Tower Hill, E. 1, at 8 p.m. Annual General Meeting, followed by a paper on "The Surface Tension of Metals," by S. W. Smith, D.Sc.

Apr. 16. Society of Chemical Industry, *Yorkshire Section*, at the Queen's Hotel, Leeds. "Some Notes on the Production of Alkali by Bacteria as Registered by Different Indicators," by J. A. Reddie.

NEWS FROM THE SECTIONS

NOTTINGHAM SECTION

A meeting under the presidency of Mr. S. F. Burford, F.I.C., was held on March 21, and a paper on "A new derivative of Salvarsan" was read by Mr. L. Anderson, M.Sc. The discovery of atoxyl by Béchamp in 1863 and of its use in experimental trypanosomiasis by Thomas and Breiul and the proof of its composition by Ehrlich and Bertheim in 1907 led to a great outburst of research directed to the preparation and use of both aliphatic and aromatic arsenicals. In attempts to combine a maximum toxicity towards protozoal diseases with a minimum injurious effect to the host Ehrlich prepared 605 compounds before salvarsan or "606" was discovered. On account of the insolubility of the free base in water, salvarsan was introduced in the form of the dihydrochloride, which had to be brought to the correct state of alkalinity before injection. The compound 914 or neosalvarsan, the sodium methylene sulphinate of salvarsan, was discovered in 1911. These two drugs have been widely used in the treatment of syphilis, but were somewhat unstable and variable in composition, the percentage of arsenic in 606 varying from 29 to 31 as against the 34·1 per cent. required by the formula; neosalvarsan was even more indefinite in composition. Fargher and Pyman showed that commercial samples of 606 contained a small amount of sulphur, which may be present in the form of sulphamic acid, but is more probably attached to the nucleus as a sulphinic acid (King). A pure sample free from sulphur was, however, more toxic than those containing this element (Fargher and Pyman). The preparation of 914 from 606 was then described. Samples of 606 and 914 prepared in 1918 by a standardised process were tested physiologically, but no definite connexion was traceable between chemical composition and toxicity. The newer salvarsan preparations such as the co-ordination compounds with metallic salts suffered from the same disadvantages, *i.e.*, variability in chemical composition which could not be connected with variability in toxicity and instability, and necessitated preservation in sealed ampoules with an indifferent gas.

In 1920 it was noticed that under certain conditions salvarsan could form a compound with glucose, with a composition corresponding with that of a compound containing two molecules of glucose to one of salvarsan. Quite recently Mons. Aubry published a description of a salvarsan diglucoside, which agreed substantially with the present compound. The therapeutic activity was tested upon mice, which had been given a standard infection of *Trypanosoma equiperdum*. These tests proved that the maximum dose tolerated (0·6 mgm. per gram body weight) was twice that of neosalvarsan. The minimum curative dose was only slightly greater than that of good samples of neosalvarsan, and the ratio of curative dose to tolerated dose was one-twentieth for the glucoside and one-fifteenth for neo-salvarsan. Extensive clinical tests with the new preparation, which had been called stabilarsan, had been equally satisfactory.

In the discussion which followed, Mr. Wilkie described a method of determining arsenic in organic compounds, viz., ignition with acid magnesium nitrate, which converted the arsenic into the quinquevalent form. This was followed by reduction with iodides and titration. Dr. Marshall referred to the discovery by Ehrlich of the phloroglucinaldehyde and resorcinaldehyde derivatives of salvarsan which, however, were found to decompose too slowly. The author, in reply, gave his reasons for supposing that one molecule of glucose was attached to each amino group.

Dr. E. B. R. Prideaux then read an abstract of two papers, one in conjunction with Mr. A. O. Bentley, Ph.C., on the theory of acid-alkali equilibrium as applied to salts of fairly strong but sparingly soluble acids, and the application to the determination of total alkali and total acid in benzoates and salicylates. After a brief survey of pharmacopœial and other methods in use, an account was given of the equations by which the acidity could be determined in the case of fully neutralised benzoates and salicylates of the alkalis and the free acids themselves in their saturation, and lower, concentrations. Methods had been worked out for determining separately both the total alkali and the organic acid in sodium benzoate and salicylate and ammonium benzoate The total alkali was checked by ignition to carbonate in the first two cases and some modifications in the ignition procedure were suggested. The salts might be decomposed with a known excess of standard acid, followed by filtration of the organic acid and its titration. The acid filtrate might be either extracted with chloroform and titrated, or both mineral acid and dissolved organic acid determined by titration with an acid insensitive indicator and phenolphthalein successively, using a factor calculated from the constants. A much quicker method was also described, in which the titration was carried out in the same flask with chloroform, using bromphenol blue with benzoates, followed by phenolphthalein.

The results showed that samples might appear correct by the ashing test but might really contain an excess of alkali over organic acid. The above titrations were not so exact with salicylates, but a procedure was given by which these also could be analysed.

In the discussion Mr. Wilkie referred to an improvement in the ignition method, consisting in titrating the liquid containing the dark carbonaceous residue with acid, iodide iodate mixture and thiosulphate and starch. He also described a method by which salicylic acid was quantitatively precipitated as tri-iodophenol.

The second lecture to commemorate the foundation of the Sir Jesse Boot chair of chemistry at University College, Nottingham, was given by Professor F. S. Kipping, F.R.S., at the College on March 23. The lecturer dealt with the evolution of the cellulose industry. The nature and purification of the raw material, the production and properties of collodion, guncotton and other cellulose nitrate products, and of the various forms of artificial cellulose threads were illustrated by numerous experiments and slides. The lecture terminated with an appeal to manufacturers to devote some proportion of profits to the payment of research chemists as a form of insurance against such periods of depression as had now overtaken an important branch of the local industries.

GLASGOW SECTION

The annual meeting was held on March 23, Mr. W. E. Moodie, F.I.C., in the chair. The Hon. Local Secretary presented his annual report and submitted a financial statement. Mr. Douglas A. MacCallum, the representative of the section on the Glasgow Chamber of Commerce, reported on the work done by the Chamber during the past year, and was re-elected as the representative of the section. The following office-bearers and members of Committee were elected: *Chairman*, Mr. W. E. Moodie, F.I.C.; *Hon. Local Secretary*, Dr. J. A. Cranston; *Members of Committee*, Prof. R. A. Berry, Mr. R. M. Clarke, Mr. W. M. Cumming, and Prof. T. S. Patterson. It was decided to hold the meetings of the section at 6.45 p.m. on the last Friday of each month during the winter months. After the business meeting a smoking concert was held, at which members of the local section of the Institute of Chemistry were present.

MEETINGS OF OTHER SOCIETIES

OIL & COLOUR CHEMISTS' ASSOCIATION

A discussion on Mr. A. de Waele's paper on "Viscometry and Plastometry," read at the February meeting, took place on March 8.

The author referred to a further conception of plasticity in heterogeneous systems, in that this property may be of two kinds: that due to flocculation of the disperse phase to form a definite aggregated structure, and the plasticity obtaining in deflocculated systems. Green (*J. Ind. and Eng. Chem.*, 1923, February, Vol. 15, p. 122) had ascribed plasticity in all cases to flocculation of the disperse phase to an aggregated structure, but the author pointed out that increased viscosity in a system on introduction of a solid or liquid disperse phase when the latter remained truly dispersed as primary particles would be accompanied by the manifestation of plasticity as shown by the diminution of the exponent ϕ of Q from unity to a fractional value. The increase of viscosity in this case was explainable by the increased shearing of the adsorbed layer around the dispersed phase as the "free" continuous phase diminished in amount relatively to the latter. This adsorbed layer immediately surrounding the dispersed particles might well be assumed to possess a higher viscosity than the "free" continuous phase that did not come under the influence of surface forces due to the adsorbing or attractive effects of the disperse phase. An analogy to the change in physical properties suffered by the continuous phase on adsorption was seen in the loss of vapour pressure which resulted by introduction of disperse phase in many instances familiar to paint technologists, *e.g.*, wax in turpentine. The retardation in the rate of evaporation was not so manifest in flocculated systems which obviously might not be expected to have a large proportion of the medium present otherwise than in a "free" condition, *i.e.*, not affected by adsorption. The author's experience led him to believe that plasticity in non-flocculated systems was always characterised by close or diagonal piling and also possibly the complete absence of the slippage *régime* on shearing. Flocculated systems, on the other hand, depended mainly for their plasticity on the interlocking of the particles of the disperse phase to form a structure. The characteristic of such a structure was its temporary breaking down on shear to a deflocculated system, thus resulting in defying any attempt to obtain agreement in ϕ and ξ values characteristic of its "consistency" by mere comparison of these values through two or more differently dimensioned capillaries. Extrapolation of such values might, however, result in cutting out the deflocculating effect of the capillary, but this had not yet been tried. It was thus obvious that in such flocculated systems a definite force necessary to overcome the coherence of the structure would be shown on shearing through a capillary, a force possibly identical with Hardy's conception of static viscosity in dry friction, but its direct recognition as in Bingham's plastic-flow law was impossible.

The static force of coherence in flocculated systems was probably identical with the coefficient of elasticity, a factor which would have the effect, actually experimentally realised, of resulting in a greater diameter in the plug of material extruding on shear through a capillary than that of the orifice of the latter.

OPTICAL SOCIETY

Two papers were read at the meeting held in the Imperial College of Science on March 8, with Sir F. Dyson, presiding.

Mr. H. D. Taylor contributed a paper on "Optical Designing as an Art," in which he showed that the best optical designing is more than the mere mathematical calculation and execution of a specification. The points raised in the paper were illustrated by reference to lenses such as those of Cooke, worked out entirely from algebraic formulæ.

In the second paper Mr. T. Smith, M.A., described the distribution of corrected duties in optical instruments.

SOCIETY OF GLASS TECHNOLOGY

Prof. W. E. S. Turner, D.Sc., presided at the meeting held in the University, Birmingham, on March 21. The papers presented were all contributions from the Department of Glass Technology, the University, Sheffield.

The first paper, entitled "A Rapid Method of Testing the Durability of Glassware," by Mr. H. S. Blackmore, Miss V. Dimbleby, and Prof. W. E. S. Turner, was read by Miss V. Dimbleby, who was thus the first lady to read a paper before the Society. The test provided a simple and rapid method for determining whether a sample of glass would withstand weathering sufficiently to enable it to fulfil certain purposes. When a solution of one part in 1000 of the alkaloid narcotine hydrochloride was heated to boiling in a glass vessel, the alkaloid was thrown out of solution, and could be seen as a fine precipitate if the glass was of poor quality. If this occurred after heating for 10 minutes, the glass was to be condemned; if within 20 minutes, the glass, although better, was still unsatisfactory. Good glasses should not show any deposit after heating at boiling point for an hour. This test differed from all others in that it required no special chemical knowledge, could be carried out with very simple apparatus, and could be applied in any factory; it had been proved thoroughly satisfactory by many trials on all kinds of glassware.

The two other papers contributed were "The Corrosion of Fireclay Refractory Material by Glass and Glass-making Materials," by Mr. Donald Turner and Prof. W. E. S. Turner, and "The Effect of Saltcake in Corroding Fireclay Materials," by Miss Edith M. Firth, Mr. F. W. Hodkin and Prof. W. E. S. Turner. These two papers were taken together and presented by Prof. Turner, who detailed experimental evidence showing that in glass melting the corrosion of the pots or of the tank blocks was most severe during the early stages of the melting of the batch. The corrosion due to the glass itself was proved to be very much less. Of the glass-making materials, sodium nitrate, potassium nitrate, and borax were particularly corrosive. Resistance to corrosion could be improved by firing the pots or blocks at 1400° C. before inserting the charge of batch. At about 800° or 900° C. saltcake was not nearly so corrosive as soda ash. At the temperature of the melting furnace, however, it appeared to be more corrosive, and it was found that as the proportion of saltcake increased, so did the extent of corrosion, even in batches in which coke, as a reducing agent for the saltcake, was present throughout.

CORRESPONDENCE

THE FORMULA OF PHOSPHORUS PENTACHLORIDE

Sir,—The formula of phosphine, according to the octet theory, is written $\begin{array}{c}\mathrm{H}\\ \cdot\cdot\\ \mathrm{H}:\mathrm{P}:\\ \cdot\cdot\\ \mathrm{H}\end{array}$ The formula of phosphorus trichloride may be written analogously as $\begin{array}{c}:\ddot{\mathrm{Cl}}:\\ :\underset{\cdot\cdot}{\ddot{\mathrm{Cl}}}:\underset{\cdot\cdot}{\ddot{\mathrm{P}}}:\\ :\underset{\cdot\cdot}{\mathrm{Cl}}:\end{array}$ The latter formula assumes that phosphorus trichloride is not an electrolyte.

The formula of phosphorus pentachloride may be written $\begin{array}{c}:\ddot{\mathrm{Cl}}:\\ (:\underset{\cdot\cdot}{\ddot{\mathrm{Cl}}}:\underset{\cdot\cdot}{\ddot{\mathrm{P}}}:\underset{\cdot\cdot}{\ddot{\mathrm{Cl}}}:)\\ :\underset{\cdot\cdot}{\ddot{\mathrm{Cl}}}:\end{array}^{+}\ :\underset{\cdot\cdot}{\ddot{\mathrm{Cl}}}:^{-}$ which is analogous to that of ammonium chloride $\begin{array}{c}\mathrm{H}\\ (\mathrm{H}:\underset{\cdot\cdot}{\ddot{\mathrm{N}}}:\mathrm{H})\\ \mathrm{H}\end{array}^{+}\ :\underset{\cdot\cdot}{\ddot{\mathrm{Cl}}}:^{-}$

If this is correct, phosphorus pentachloride should be an electrolyte. I hope to test this point if a suitable solvent can be found.

Phosphorus oxychloride may be regarded as the result of combination of $\begin{array}{c}:\ddot{\mathrm{Cl}}:\\ :\underset{\cdot\cdot}{\ddot{\mathrm{Cl}}}:\underset{\cdot\cdot}{\mathrm{P}}:\\ :\underset{\cdot\cdot}{\mathrm{Cl}}:\end{array}$ with $\underset{\cdot\cdot}{\ddot{\mathrm{O}}}:$ giving $\begin{array}{c}:\ddot{\mathrm{Cl}}:\\ :\underset{\cdot\cdot}{\ddot{\mathrm{Cl}}}:\underset{\cdot\cdot}{\ddot{\mathrm{P}}}:\underset{\cdot\cdot}{\ddot{\mathrm{O}}}:\\ :\underset{\cdot\cdot}{\mathrm{Cl}}:\end{array}$

The tertiary amine oxides would then be $\begin{array}{c}\mathrm{R}_1\\ \mathrm{R}_2:\underset{\cdot\cdot}{\ddot{\mathrm{N}}}:\underset{\cdot\cdot}{\ddot{\mathrm{O}}}:\\ \mathrm{R}_3\end{array}$

Now Meisenheimer has obtained free methylethylphenylamine oxide in optically active form, and it has been suggested that the two valencies of the oxygen are satisfied by two unlike valencies of the nitrogen (*Ber.*, 1908, 3971).

If we adopt the formula $\begin{array}{c}\mathrm{Me}\\ \mathrm{Et}:\underset{\cdot\cdot}{\ddot{\mathrm{N}}}:\underset{\cdot\cdot}{\ddot{\mathrm{O}}}:\\ \mathrm{Ph}\end{array}$ oxygen appears to be linked by one valency only and the asymmetry may resemble more closely that of asymmetric carbon, than has been supposed, for the case of the tertiary amine oxides.—I am, Sir, etc.,

G. W. F. Holroyd

Blackburn
March 23, 1923

AN EMPIRICAL RULE FOR SUBSTITUTION IN BENZENE DERIVATIVES

Sir,—In view of the attention which is now being given to the electronic theory of valency, I think the following contribution may be of interest to your readers.

You will see that negative and positive groups are clearly defined, and that the rule introduces an arithmetical consideration into the difficult theory of substitution in the benzene derivatives, which makes it very simple to use. For these reasons it is likely to be of service to chemists.

Several rules have been brought forward by different authors to explain the influence of different groups in mono-substituted benzene derivatives, which directs the new substituent to the ortho and para, or to the meta positions.

The best known of these rules is that of Crum-Brown and Gibson; others have been formulated by Hübner, Noelting, Armstrong and Vorländer.

The rule given in this paper is based on the model of the atom known as the Thomson and Lewis-Langmuir atom; that is a system of electrons in concentric shells round a positively charged nucleus. The outermost shell of electrons contains those which are concerned in chemical reactions and impart to the element its characteristic property of valency. They are known as valency electrons. Elements in the same group in the Periodic Table have the same number of electrons in their outside shells, although they have different inner shells and nuclei.

The number of valency electrons for the first element in each group is as follows:—He O, Li 1, Be 2, B3, C 4, N 5, O 6, Fl 7. Hydrogen is unique and has only one electron besides its inner positive nucleus.

In accordance with Sir J. J. Thomson's theory of valency, atoms tend to surround themselves with octets of electrons. An atom can do this by adding on to its own valency electrons those of other elements, and Langmuir has applied this conception successfully to explain the combination of elements in chemical compounds. Lapworth and Robinson have extended the ideas. In their respective papers on the polarity of atoms, they have given a very comprehensive survey of the ways in which this conception can be used to elucidate the problems of organic chemistry. The rule given in this paper furnishes a practical illustration of the application of these views. The rule is:—If the number of valency electrons in the atoms of the group present in the benzene derivative be added together and those groups which have one less electron than the number required to make a whole number of octets be called negative groups and those with one more electron be called positive groups, then *negative groups lead to ortho para substitution and positive groups to meta substitution.*

A glance at the following tables will show that this is true of the majority of simpler groups :—

Negative Groups	No. of Electrons	Difference from whole number of octets	Substitution
—Cl	7	8—1	o. p.
—Br			
—I			
—OH	7	8—1	o. p.
$-CH_3$, *i.e*, 4+3	7	8—1	o. p.
$-NH_2$ „ 5+2	7	8—1	o. p.
—CNS	15	16—1	o. p.
—CNO			
$-CH_2COOH$	23	24—1	o. p.
$-NH.CO.CH_3$	23	24—1	o. p.

Positive Groups	No. of Electrons	Difference from whole number of octets	Substitution
—CN	9	8+1	m.
—COOH	17	16+1	m.
$-NO_2$	17	16+1	m.
$-COCH_3$	17	16+1	m.
$-SO_3H$	25	24+1	m.
$-C\ Cl_3$	25	24+1	m.

A consideration of the arrangement of the valency electrons within each of the above groups is outside the present scheme.

The ethylene linkage forms a special case. It is recognised that when two carbon atoms are joined by a double bond, four valency electrons are held in common by the octets of these atoms and two octets are formed from 12 electrons. Four electrons must, therefore, be subtracted from the total number of valency electrons of any group containing an ethylene linkage before deciding whether the group is negative or positive. Thus, $-CH{=}CH\ COOH$ in cinnamic acid has 27 electrons. If four are substracted this gives 23. It is a negative group and gives orthopara substitution. The same reasoning can be applied to linked methylene groups. Two electrons are shared and two octets are formed from 14 electrons —so two electrons must be subtracted in this case before applying the rule.

There are many groups not included under these two headings whose sum total of valency electrons is nearly half way between the numbers required for 1, 2, 3, 4, etc., octets.

The aldehyde group,—CHO, has 11 electrons, and groups with 13 electrons are very common, *e.g.*, CH_2Cl, CH_2OH, OCH_3, etc.

These groups give all three derivatives or mixtures of meta with ortho or para derivatives, but ortho and para, or meta derivatives will predominate according to whether the group is more nearly negative or positive. The aldehyde group with 11 electrons is nearer to 8+3, than to 16—5 and will give mainly meta derivatives. Probably the group entering may exercise a directing influence as well in these cases.

No explanation is attempted here of cases where tri derivatives are formed instead of di derivatives as in chlorinating aniline and phenol, of cases where only side chain substitution occurs, or of changes brought about by varying conditions of temperature.

I am extending the inquiry to other benzene derivatives.—I am, Sir, etc.,

Dorothy Hoffert

The Lister Institute, London

March 26, 1923

"CHEMIST" AND OTHER TITLES.

Sir,—While I fully sympathise with the President of the Institute of Chemistry as regards the common abuse of the title "chemist," I should like to point out that the grievance does not end there. If we are to stop abuses of the English language, there are other and equally glaring inaccuracies that call for attention.

One of these is the constant misuse of the title " Doctor." A Doctor is a man who holds a *Doctor's* degree, whether it be in medicine law, science, music or philosophy. There is a distinct movement on the part of the medical profession to monopolise the title, whether they possess a Doctor's degree or not. Every M.B. and every L.R.C.P., or even L.S.A., now calls himself " Doctor," and I have known some of them to put " Dr." on their visiting cards. I saw on a garage the other day the sign, " —— and Co., Motor Doctors " ! Medical men sometimes go so far as to refer to Doctors in other faculties as " Mr.," merely adding the letters of their degree.

As a large number of chemists hold the degree of Doctor, either in science or in philosophy, it is desirable in their interests that this should be insisted on as well as the title of " chemist."—I am, Sir, etc.,

" Doctor of Science "

March 26, 1923

THE MEANING OF THE WORD " GAS "

Sir,—Your reference to the etymology of the word ' gas ' in the last number of *Chemistry and Industry* raises an interesting point. The question of the derivation of some of our chemical terms may not be regarded by the pragmatists of the profession as of great import, but to those who are interested in the historical development of chemistry (and what a fascinating story it is !) it matters much, as only by an exact interpretation of the language of the pioneers can a clear impression of their views be obtained. In this connexion it is remarkable how an error (or perhaps a half-truth) once established, will persist throughout generations of text-books. The word ' gas ' is a case in point. I do not remember any text-book (except Mellor) that gives what I feel must be the correct derivation of the term. It is usually supposed to be derived from the German ' geist,' spirit, and to be cognate with our word ' ghost.' This is certainly a very attractive and, at the same time, satisfying theory, but it would have been a simpler transition had van Helmont (who, by the way, was a Belgian) adapted the Old English ' gast ' from which 'ghost' is derived. The admirable summary of the evidence given in Mellor's treatise seems to me entirely convincing. The Greek 'chaos' signified the confused mass of elemental substance, and also space or atmosphere. Paracelsus used the word with a similar meaning. It must be remembered that van Helmont considered water to be the primal substance, and it was to the vapour rising from water (as well as to his 'gas sylvestre') that he gave the name 'gas,' at the same time pointing out its analogy with the 'chaos' of the ancients. The term 'spirit' had been used for centuries to denote aëriform elastic fluids, and in the seventeenth century the word was in common use for several well-known gases. It is not surprising, then, that some should seek, quite ingeniously, to associate the new word with the German or Dutch equivalent for 'spirit.' I should add that the Oxford English Dictionary makes no mention of the Teutonic derivation of the word.—I am, Sir, etc.,

Leslie N. Brown

West Kensington,
March 19, 1923

PERSONALIA

Mr. G. E. Foxwell, M.Sc., has been awarded the annual bronze medal of the International Metallurgical and Chemical Society for his researches on the path of travel of the gases in the coke oven and for his work on ammonia. Mr. Foxwell is the chief chemist and physicist to the Koppers Coke Oven Co., Ltd.

Dr. L. H. Cretcher has been appointed head of an industrial fellowship at the Mellon Institute, Pittsburgh, to investigate the synthesis of chemicotherapeutic products.

Mr. W. F. Lantz has succeeded Mr. A. D. Shankland as chief chemist at the plant of the Bethlehem Steel Co., Bethlehem, Pa., and Mr. D. K. Pattillo has become research chemical engineer to the Western Electric Co., Chicago.

Doctorates of Philosophy of London University have been conferred on Mr. F. H. Mosharrafa for a thesis on the "Quantum Theory of Spectral Series"; on Mr. W. S. G. P. Norris for his thesis on the "Formation and Stability of Spirane Hydrocarbons"; and on Miss E. H. Usherwood for her thesis on the "Formation of Heterocyclic Rings involving Reactions with the Nitroso- and Nitro-groups in their various Tautomeric Modifications," and "Experiments on the Detection of Equilibria in Gaseous Tautomeric Substances."

* * *

The death is announced at the age of seventy-nine of Dr. Ernst Salkowski, director since 1880 of the Chemical Division of the Berlin Pathological Institute. Dr. Salkowski had published numerous researches on the metabolism of the carbohydrates, and his treatise on Physiological and Pathological Chemistry is widely reputed.

NEWS AND NOTES

BRITISH INDIA

Forecast of the Groundnut Crop, 1922-23

The total area returned in the final forecast of the groundnut crop in British India is 2,530,000 acres, the total yield being estimated at 1,157,000 tons of nuts in shell, figures which represent increases of 18 to 21 per cent., respectively, over those given in the final forecast for last year. The forecast relates to the provinces of Madras, Burmah and Bombay, which comprise 99 per cent. of the entire groundnut area of British India.—(*Ind. Tr. J.*, *Mar.* 1, 1923.)

CANADA

Hydro-Electric Progress in 1922

The Water-Power Branch of the Canadian Department of the Interior has published figures showing that during 1922 the total water-power installation in Canada rose to approximately 3,000,000 h.p. of which 240,000 h.p. was installed during the year. This figure does not include 190,000 h.p. installed during 1921, but brought into operation in 1922. Schemes are in progress which will ultimately develop over 1,000,000 h.p., thus showing that the utilisation of the water-power resources of Canada is continuously progressing. Among the chief developments of recent date are schemes to increase the output of existing plants in British Columbia, the development of the Manitoba Power Co. at Great Falls on the Winnipeg river, where the first unit of 168,000 h.p. was put into service in December last, and the rapid increase of the plant installed by the Ontario Hydro-Electric Commission at Queenston, as well as immense developments on the Saguenay river, and at Gres Falls on the St. Maurice river in Quebec. Hydro-electric development is also progressing steadily in the Maritime Provinces.—(*Bd. of Trade J.*, *Mar.* 22, 1922.)

SOUTH AFRICA

Matsap Pan: A Potential Source of Nitrates

The February issue of the *South African Journal of Industries* contains a report contributed by the Director of the Geological Survey on the Matsap Pan, situated in the Hague district. This Pan is remarkable in that it consists of an underground store of nitrate-bearing brine. Analyses of the brine from several boreholes show that over 4½ tons of actual nitrates, mostly sodium nitrate, are to be found in every 20,000 gallons of brine. Nitrate also occurs in other waters in the district, and this shows that underground water in that locality carries nitrates, the accumulation of salts in the pan being due to concentration of the solutions. It is stated that if the supply of brine were large enough, it might be economically possible to recover the nitrates, but this could only be ascertained by continuous pumping. Brine is already pumped in quantity from the depths of many South African salt pans, *e.g.*, the Britten pan, which yields 250,000 gallons a day. The separation of the nitrates is being investigated by a German chemist at Stassfurt. South Africa imports nitrates to the value of about £300,000 annually for the manufacture of explosives, and this should stimulate the exploitation of this new source of nitrates.

UNITED STATES

Magnesite in 1921

Magnesite is produced in the United States chiefly in California and in Washington, but production has ceased in the latter State. Sales of crude magnesite during 1921 amounted to 47,904 short tons, as against 303,767 t. in 1920, whereas imports of crude magnesite totalled 51,993 t. and of calcined magnesite 6788 t., of which the greater part came from Italy and Austria, and smaller amounts from Germany and Greece. The average consumption of crude magnesite in the United States was about 300,000 short tons per annum prior to the war.

Magnesium in 1921

The United States Geological Survey states that only one company, the American Magnesium Corporation, of Niagara Falls, reported a production of metallic magnesium in 1921, the output being 10,044 lbs., much less than in previous years. This output, as in 1920, was obtained incidentally in experimental operation in furnaces, and was derived from Californian magnesite. Small amounts of magnesium alloys, castings, and ribbon were also sold, but stocks at the end of the year exceeded the production of new material. The average price during the year was $1·60 per lb. for metal and $2·25 per lb. for powder. Imports during the year amounted to 39,913 lbs. compared with 29,275 lbs. in 1920, and the average price was brought down to $0·77 by German competition. Progress was made during the year in improving the purity of the metal, which, it is now claimed, can be produced commercially with a purity of 99·98 per cent. Future developments would appear to depend on the increasing use of magnesium alloys for engineering purposes.

FRANCE

The Dyestuffs Industry

Before the war, the French dyestuffs industry was but little developed, requirements being obtained either from branches of German factories situated in France, or imported. During the war, however, every effort was made to develop the industry and in 1920, 7400 m.t. of various dyestuffs was manufactured, an increase of 4400 t. over the output in the previous year. Of the production in 1920, 40 per cent. consisted of indigo, 35 per cent. of Azo dyes, and 21 per cent. of Sulphur dyes. Although roughly 5900 t. was imported, yet over 3000 t., consisting chiefly of indigo, was exported. In 1921, the production was only 5900 t., including 45 per cent. of indigo, 32 per cent. of Azo dyes, 3 per cent. of Di and Triphenylmethane dyes, and 14 per cent. of Alizarin dyes, the last-named appearing for the first time in the French production. Imports during 1921 were reduced to 1200 tons, representing 16·4 per cent. of the total consumption. Exports were also reduced, falling to 2700 tons. The range of dyes manufactured considerably increased, and allowing for the economic crisis, the production was satisfactory. The situation improved considerably in 1922, the average monthly production (612 t. in 1920 and 488 t. in 1921) rising to 670 tons, the increase being due not to the heavier production of old dyes, but to the manufacture of new ones, especially of Di and Tri-phenylmethane and Alizarin dyes. Exports decreased, but imports in 1922 represented only 15·3 per cent. of the total consumption. Considerable progress has thus been made in establishing the dye-making industry in France, but the difficulties which it has had to face have not entirely disappeared, the chief one being the fiscal protection necessary for a young and growing industry. But even fiscal protection can do little when faced with the enormous depreciation of the currency in competing countries, and a solution has yet to be found—(*Chim. et Ind., Jan.*, 1923).

GENERAL

Research in Cambridge

The third report of the Board of Research Studies announces that the number of research students has risen to 179. Of these about two-thirds are working on scientific subjects, chemistry and physics having the largest number, followed by botany, agriculture and bio-chemistry.

New Oilseed from the Gold Coast

A sample of Kisidwe nuts was shown at the National Rubber and Tropical Products Exhibition held in London in 1921. As no detailed examination of these nuts had previously been made, the possibility of using them as an oilseed was investigated at the Imperial Institute. The nuts appear to belong to a species of *Allanblackia*, probably *A. floribunda*, and have an oil-content equivalent to 44·2 per cent. of the entire nuts. They should therefore be utilisable as an oilseed if available in sufficient quantities. The fat could probably be used for food and certainly for soap-making. The removal of the shell, which is thin, and forms only 38 per cent. of the nut, would present no difficulty. As the residual meal has a bitter taste, this prevents its employment as a feeding stuff. The meal contains no alkaloids or cyanogenetic glucosides, but a small amount of tannin, which accounts for the bitter taste. —(*Bull. Imp. Inst.*, XX, *No.* 4, 1922.)

REVIEW

Dyes and their Application to Textile Fabrics. *By* A. J. Hall. *Pitman's Common Commodities and Industries. Pp.* ix +118. *London: Sir Isaac Pitman and Sons, Ltd.*, 1923. *Price* 3*s. net.*

Structural organic chemistry is ill-adapted to popular treatment and to produce a book which the non-technical reader will find " interestingly instructive " is no light task. Mr. Hall is, therefore, to be congratulated on his achievement. The book, however, is badly described by the title, as out of the 116 pages of text only 31 pages are devoted to the dyes, and of these 11 pages deal with the history of the subject. The main portion of the book is devoted to the application of the dyes, and although the descriptions are necessarily very brief they are lucid and might be read with advantage by many chemists who have not specialised in the subject. The description of printing processes, however, is too short and might be extended in the next edition.

As the chapters dealing with the dyes could hardly be followed by a reader completely ignorant of elementary chemistry the rather laboured explanations of chemical formulae might be omitted. The explanation of the term " molecule " (page 14) would probably mislead a reader completely ignorant of chemistry and such a reader would probably get quite a wrong idea of the determination of structure from the explanation that " chemists are able by special methods to *look* as it were into the molecule of a substance and *see* how it is built up." (The italics are the reviewer's).

Very few misprints have been detected, the most obvious being the statement on page 45 that *aqua regia* is a mixture of nitric and sulphuric acids. The printing and general get-up are excellent and the literary style satisfactory except for an occasional split infinitive and the author's irritating habit of commencing his sentences with " So," " And " and " But."

E. de Barry Barnett

REPORT

Report on the Economic Situation of the Republic of Ecuador, September, 1922. *By* W. C. Graham, *Acting British Consul-General, Quito. Department of Overseas Trade. Pp.* 22. *H.M. Stationery Office*, 1923. *Price* 9*d.*

This report on Ecuador opens on an even more hopeless note than the last (*see* J., 1921, 317 r), the present bad state of the country being attributed not only to decreased trading but also to the large and increasing public debt, and to faulty methods of collecting and disbursing the national revenue. The Minister of Finance has put forward a scheme for improving matters. The Government monopolies on alcohol, tobacco, explosives, and salt are leased to corporations or individuals, generally with disastrous results. The alcohol monopolists have the power, which they exercise, of restricting sugar-cane cultivation, and, though sugar might be one of the principal exports of the country, it now has to be imported. Petroleum regions are held by the State and leased out, little work being anticipated under the terms of the leases; the present annual production is about 40,000 barrels. New industries are favoured in the matter of taxation, and some few are being established A cotton print works is being set up at Quito, and a new cement works at Guayaquil will, it is hoped, produce about 60,000 barrels per annum.

The detailed trade figures given are for 1920. Exports during this period amounted to £4,989,193 (at the nominal rate of 10 sucres to the £, though the present figure is nearer 20), of which the United States took 55 and the United Kingdom 17 per cent., compared with £4,322,055 in 1919 (U.S. 46%, U.K. 17%). In 1920 as usual cocoa made up the bulk of the export trade, 46,780 metric tons being sent out of the country. Other items were ivory nuts, 23,099 t.; coffee, 1588 t.; tobacco, 374 t.; cotton, 210 t.; rubber, 139 t. Imports increased from £2,400,769 in 1919 (U.S. 70%, U.K. 14%) to £4,017,451 in 1920 (U.S. 58%, U.K. 24%). In 1920 the imports included cement, etc., £28,239; china and glass, £62,476; candles, £51,590; drugs and chemicals, £131,758; minerals and fuels, £979,861; paints, varnishes and enamels, £51,763; perfumery, etc., £85,934. Estimates for 1921 indicate that exports remain higher than imports, the former being valued at £3,396,889 and the latter at £2,348,619.

PARLIAMENTARY NEWS

Production of Morphia and Heroin

Answering Captain J. Hay, Mr. Bridgeman said that during 1921, 147,790 ozs. of morphine was manufactured in this country and 77,364 ozs. exported; the corresponding figures for heroin were 12,385 and 14,107 ozs. No figures were available to show the amount used in this country, but the balance would be disposed of for medical and scientific purposes through dealers licensed under the Dangerous Drugs Act.—(Mar. 22.)

Imports of Glassware

Sir P. Lloyd-Greame, in reply to Major Kelley, said that the declared value of glass bottles and jars imported into the United Kingdom during the first two months of 1923 was £133,248, and of other glassware £554,855. He had no information regarding the value of the output of such articles in this country during the same period.—(Mar. 22.)

Plantation Rubber Industry

Mr. Ormsby-Gore, answering Sir B. Chadwick, said that the Government intended to continue the policy initiated by the Colonial Secretary to safeguard the plantation rubber industry.—(Mar. 19.)

German Reparation (Recovery) Act, 1921

A motion by Capt. W. Benn to suspend the operation of the German Reparation (Recovery) Act was defeated by 144 votes to 77. In the discussion, Mr. Baldwin said that up to the present rather over £10,000,000 had been received in duties paid under the Act, so that we were receiving between £7,000,000 and £8,000,000 per annum, the only cash now paid in any form of reparations, except for maintaining the Army of Occupation.—(Mar. 26.)

Dyestuff (Import Regulation) Act

Replying to various questions, Sir P. Lloyd-Greame said that benzoic acid was an organic intermediate, and so came within the scope of the Act. He had no power to exempt any particular product from the operation of that Act, but licenses were granted for importation of quantities of benzoic acid shown to be required for purposes other than dye manufacture. When any dye could not be procured in this country, licenses to import were always given. He was satisfied that the Dyestuffs Advisory Licensing Committee commanded the confidence of the consumers generally. The Committee asked importers to state why their clients could not meet their requirements from British firms in order to give proper consideration to applications for licenses. The British Dyestuffs Corporation stated that no reparation dyestuffs had been sold by them in any way in Spain.—(Mar. 27.)

Ammonium Phosphates

Sir P. Lloyd-Greame, replying to Mr. H. Simpson, said he did not agree that the material largely used for fire-proofing was generally known in commerce as ammonium phosphate. Ordinary grades of this compound were removed from the dutiable list owing to opinions expressed by the Referee. No complaint as to the inclusion of ammonium biphosphate was received within the prescribed period, and he had no power to remove it from the list. Since the Act became law, a large British production had become available, and the price was now much less than when there was no British manufacture.—(Mar. 27.)

Arc-lamp Carbons

In answer to Mr. Hogge, Sir P. Lloyd-Greame said that inquiries were being made as to the position and progress in this country of all the industries covered by Part I. of the Safeguarding of Industries Act, including arc-lamp carbons. As part of these inquiries, the views of representative users of both British and foreign carbons were being sought. The duty paid on imported arc-lamp carbons during 1922 under Part I. of the Act was £5170.—(Mar. 27.)

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for March* 29)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of firm or agent	Materials	Reference number
Austria, etc...	Rubber, asbestos, and other raw materials, pig iron, iron plates..	398
British East Africa	Disinfectants, wood preservatives ..	391
Bulgaria ..	Medicaments	10222/F.E./C.C./2
Canada ..	Druggists' supplies ..	392
" ..	Tinfoil, glass bulbs for electric lamps ..	393
Esthonia ..	Chemicals, oils, paint, varnish	401
France ..	Linseed oil	402
Netherlands ..	Refractories, earthenware	405
New Zealand	China, earthenware, glassware	396
Rumania ..	Porcelain insulators (tender for)	10335/F.E./E.C./2
South Africa..	Pyridine, Simonsen's oil, wood naphtha for denaturing alcohol ..	10856/E.D./C.P.
United States	Iron and steel material, tinplate, etc.	18677/F.W./E.C./B./2

TARIFF CUSTOMS EXCISE

Belgium.—The issue for March 29 contains a translation of the proposed new customs tariff.

Egypt.—Revised valuations have been issued for use in assessing the duties on imports of non-ferrous metals.

France.—The exportation of molasses is prohibited.

Germany (*Occupied*).—A summary of the regulations concerning trade control and tariffs in force in the occupied territory is given in the issue for March 29.

Mauritius.—An increased import duty is payable on tinctures not prepared according to official formulæ.

Poland.—The surtax on the duties payable on blown glass, acetic acid, wood spirit, and acetone has been increased to 299,900 per cent.

South Africa.—Preparations containing one-fifth or more per cent of anhydrous morphine are now classed as habit-forming drugs under the regulations controlling the importation and sale of such drugs.

MARKET REPORT

This Market Report is compiled from special information received by the Secretary from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities nett and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech. ..	£23-£25 per ton. Very firm with little available. Complete absence of German supplies.
Acid Hydrochloric ..	4s.-5s. carboy.
Acid Nitric	£24 per ton. No signs of improvement.
Acid Sulphuric	Average national price for Crude Tower Acid, 140° Tw., is 70s. f.o.r. makers' works, with slight variations up and down due to local considerations.
Acid Sulphuric, 94% arsenical	£6 10s. per ton.
Ammonia Alkali ..	£7 12s. 6d.-£8 per ton. Steady demand. Continental inquiries more frequent.
Arsenic (White) ..	£70-£75 per ton. Market steady.
Bisulphite of Lime ..	£7 per ton. Packages extra.
Bleaching Powder ..	£10 10s. d/d. No change. Spot demand poor.
Calcium Chloride ..	£6 per ton d/d.
Copper Sulphate ..	£27 per ton. Somewhat firmer.
Potash Caustic, 88/90%	£35 per ton. Considerably advanced in value. No German supplies.
Potass. Bichromate ..	5¾d. per lb. d/d. buyer's works.
Salammoniac	£32 per ton d/d.
Salt Cake	£4 10s. per ton. Normal.
Soda Caustic, 76% ..	£20-£21 per ton. Demand good, especially for the Continent.
Soda Crystals	£5 5s. carr. paid. No change. Demand quite good.
Sod. Bicarbonate ..	£10 10s. per ton.
Sod. Acetate, 97/98% ..	£25 per ton.
Sod, Bisulphite Powder, 60/62%	Ton lots. £19 .. 10 £19 10s. 5 £20 .. 2 £20 10s. 1 F.o.b. or f.o.r. London, 1-cwt. iron drums incl'd.
Sod. Chlorate	3d. per lb. Demand not quite so brisk with better supplies.
Sod. Nitrite, 100% basis	£28 per ton d/d.
Sod. Sulphide, conc. ..	£15 conc. solid carr. paid. Better demand.
Sod. Sulphite— Pea Crystals	Ton lots. £17 .. 2 £17 10s. 1 1-cwt. wooden kegs included.

WOOD DISTILLATION PRODUCTS

Acetate of Lime Brown	£10 per ton d/d.
,, ,, Grey ..	£20 per ton d/d.
Acetate of Lime Liquor	9d. per gall., 32° Tw.
Iron Liquor	1s. 6d. per gall., 32° Tw. 1s. 2d. per gall., 24° Tw.
Red Liquor	1s. 3d. per gall., 14/15° Tw.
Wood Creosote	2s. 6d. per gall., unrefined. Lower prices, however, are asked in some quarters.
Wood Naphtha—	
Miscible	6s. 6d. per gall., 60% O.P.
Solvent	5s. per gall., 40% O.P.
Wood Tar	£5 per ton d/d.
Brown Sugar of Lead ..	£39 per ton d/d.

TAR PRODUCTS

Acid Carbolic, crystals..	1s. 7d.-1s. 8d. per lb. Practically no change. Market well maintained for next two or three months.
,, ,, crude 60's	4s.-4s. 4d. Demand good. Business still being done at lower figure, but higher prices spoken of in some quarters.
Acid Cresylic, 97/99 ..	1s. 11d.-2s. 3d. Fair enquiries for forward delivery.
,, ,, pale 95%	1s. 10d.-2s. 2d. Moderate enquiry.
,, ,, dark ..	1s. 6d.-1s. 11d. Fair demand.
Anthracene Paste, 40%	4d. per unit per cwt. Price still nominal. No business.
Anthracene Oil—	
Strained	9¾d.-11d. gall. Fair enquiries.
Unstrained	9d. per gall.
Benzole, crude, 65's ..	1s. 1d. per gall.
Benzole, standard motor	1s. 6½d.-1s. 8d. per gall.
Benzole, pure	2s.-2s. 3d. per gall.
Toluole, 90%	1s. 9d.-1s. 11d. per gall. Little demand.
Toluole, Pure	2s. 2d.-2s. 6d. per gall. Market firm.
Xylol	3s. 3d. per gall.
Creosote—	
Cresylic, 20/24% ..	11d.-1s. 1d. Prices still steady.
Middle Oil	8¾d.-9½d. per gall. Good demand.
Heavy..	
Standard specification	
Naphtha, crude.. ..	9d.-9¼d. per gall.
,, Solvent 90/160	1s. 7d.-1s. 9d. Very little business doing.
,, Solvent 90/190	1s. 6½d.-1s. 7½d. Market still steady.
Naphthalene—	
Crude, drained Creosote salts	£7-£9. Good demand, market firm.
Crude, whizzed or hot pressed	£11-£12. Numerous enquiries for forward delivery.
Pitch, medium soft ..	185s.-200s. per ton. Market active.
Pyridine, 90/140 ..	11s.-12s.
,, heavy.. ..	8s.-9s. per gall. Price still nominal—no business.

INTERMEDIATES AND DYES

Acetic Anhydride ..	1s. 5d. per lb.
Acid H.	5s. lb. 100% basis d/d.
Acid Naphthionic ..	2s. 7½d. lb. ,, ,, ,,
Acid Neville & Winther .	6s. lb. ,, ,, ,,
Acid Sulphanilic ..	1s. 6d. lb. ,, ,, ,,
Aluminium Chloride anhydrous	1s. per lb. d/d.
Aniline Oil & Salts ..	9½d. lb. naked at works.
Antimony Pentachloride	1s. 1d. lb.
Benzidine Base	6s. 6d. lb. 100% basis.
Benzyl Chloride ..	1s. 4½d. ,, ,, ,,
p-Chlorphenol	4s. 6d. per lb.
p-Chloraniline	3s. lb. 100% basis.

p-Dichlorbenzol	£55 per ton.
Dinitrobenzene	11d.-1s. lb. naked at works.
Dinitrochlorbenzol	£95 per ton.
Dinitrophenol	£140 per ton.
Dinitrotoluene 48/50	8d.-9d. naked at works.
66/68	1s. 2d.-1s. 3d. naked at works.
Diphenylamine	3s. 2d. lb. d/d.
Dichloraniline	2s. 2d. lb. 100% basis.
Dichloraniline S. Acid	2s. 4d. per lb. 100% basis.
Diethylaniline	4s. 6d. lb. d/d. packages extra.
Metanitraniline	5s. 6d. lb. d/d.
Monochlorbenzol	£70 per ton.
α-Naphthol	2s. 9d. lb.
β-Naphthol	1s. 1d. lb. d/d.
α-Naphthylamine	1s. 6½d. lb. d/d.
β-Naphthylamine	4s. lb. d/d.
p-Nitraniline	2s. 7d. per lb. d/d.
Nitrobenzene	7d.-8d. per lb.
Nitronaphthalene	1s. lb. d/d.
o-Nitrochlorbenzol	2s. lb. 100% basis d/d.
p-Nitrophenol	1s. 9d. lb. 100% basis.
p-Nitro-*o*-amidophenol	4s. 6d. lb. 100% basis.
m-Phenylene Diamine	5s. 6d. lb. d/d.
p- „ „	12s. 6d. 100% basis d/d.
Sod. Naphthionate	2s. 8½d. lb. 100% basis d/d.
p-Toluidine	5s. lb. d/d.
m-Toluylene Diamine	5s. lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid Acetic 80%	£52 10s. Position firm.
Acid Acetyl Salicylic	2s. 11d.-to 3s. 3d. per lb. Now quoted on a firmer market. Supplies restricted.
Acid Benzoic	2s. 3d. per lb. Steady and in good demand.
Acid Boric	Unchanged.
Acid Citric	1s. 8½d. per lb., less 5%. Market steady.
Acid Gallic	3s. per lb. for 2-cwt. lots. 3s. 3d. per lb. for 56 lb. lots.
Acid Pyrogallic, cryst.	5s. 9d. per lb. Price advanced.
Acid Salicylic	2s.-2s. 6d. per lb. Very firm. Several makers cannot book further orders for some time.
Acid Tannic	3s. 3d. per lb. is the present limit.
Acid Tartaric	1s. 2½d.-1s. 3d., less 5%. Tendency continues to be upward and the volume of business is greater. Foreign makers are following the English market and have raised their prices.
Acetanilide	1s. 6d. per lb. Unchanged owing to lack of any considerable demand.
Ammon. Benzoate	3s. per lb. This price will soon have to be advanced in common with other benzoates.
„ Carbonate, B.P.	£37 10s. per ton. nett.
Atropine Sulphate	12s. 6d. oz. Steady.
Barbitone	14s.-17s. 6d. per lb. Very much advanced. Some holders are asking still higher prices.
Benzonaphthol	3s. 3d. per lb. Still further reduced.
Bismuth Salts	Unchanged. Good steady market.
Bromides	All very firm. Prices on the Continent continue to advance.
Calcium Lactate	2s. 3d. per lb. with prices hardening upwards.
Chloral Hydrate	4s. 3d. per lb.
Chloroform	2s.-2s. 3d. per lb.
Creosote Carbonate	10s. per lb.
Formaldehyde 40%	£88 to £90 per ton.
Guaiacol Carbonate	7s. 6d.-8s. 6d. per lb. now quoted in view of more demand having arisen.
Hexamine	4s. 6d. per lb. would now be wanted for quantity.
Homatropine Hydrobromide	30s. per oz.
Hydroquinone	3s. 3d.-3s. 6d. per lb.
Iron Ammon. Citrate	2s. 5d. per lb. for 1-cwt. lots.
Iron Perchloride	£20 to £22 per ton.
Magnesium Carbonate	
Light comml.	£38 per ton.
Magnesium Oxide—	
Light comml.	£85 per ton.
Heavy comml.	£28 per ton.
Menthol	32s. for original cases. Smaller quantities 33s. per lb.
Methyl Salicylate	2s. 6d.-2s. 8d. per lb. in glass containers.
„ Sulphonal	13s. 6d. per lb. now quoted.
Mercurials	Unchanged but still very firm
Paraformaldehyde	4s. per lb., advanced.
Paraldehyde	1s. 6d.-1s. 8d. per lb.
Phenacetin	6s. 6d. per lb. is now quoted being an appreciable advance on previous rates.
Phenazone	7s. 6d. per lb., now wanted.
Phenolphthalein	5s. per lb. firming up again.
Potass. Bitartrate 99/100% (Cream of Tartar)	95s.-98s. per cwt. less 2½% demand good.
Potass. Ferricyanide	4s. per lb.
Potass. Iodide	15s. 8d. per lb. for cwt. lots. Good steady demand.
Potass. Permanganate	10d. per lb. is now the minimum price for quantity.
Quinine Sulphate	2s. 3d.-2s. 4d. per oz.
Resorcin	5s. per lb.
Salol	2s. 6d.-3s. 3d. per lb. now quoted.
Silver Proteinate	9s. 6d.-10s. per lb.
Sod. Benzoate	2s. 3d. per lb., with greatly increased quotation from Germany.
Sod. Citrate	U.S.P. quality 2s. 2d. for cwt. lots.
Sod. Hyposulphite, Photographic	£14 15s. for 5-ton lots.
Sod. Potass. Tartrate (Rochelle Salt)	80s.-82s. cwt. Poor demand.
Sod. Salicylate	2s. 5d. per lb. for powder, 2s. 6d. for crystal. The position remains unaltered.
Sod. Sulphite Anhydrous	£27 10s.-£28 10s. per ton according for quantity, f.o.r. London drums included.

Sulphonal	13s. per lb. is the present value.
Tartar Emetic ..	1s. 4d. per lb. Unchanged.
Thymol	19s. per lb. for good white crystals. Lower prices would be accepted for quantity.

PERFUMERY CHEMICALS

Acetophenone	10s. 6d. per lb.
Aubepine	12s. ,, ,,
Amyl Acetate	2s. 6d. ,, ,,
Amyl Butyrate	8s. ,, ,,
Amyl Salicylate ..	3s. 6d. ,, ,,
Anethol (melting point 21/22°C.)	4s. 3d. ,, ,,
Benzyl Acetate from chlorine-free Benzyl Alcohol	3s. ,, ,,
Benzyl Alcohol free from Chlorine	3s. ,, ,,
Benzaldehyde free from Chlorine	3s. ,, ,,
Benzyl Benzoate, 19.5°C.	3s. ,, ,,
Cinnamic Aldehyde—	
98/100% Natural ..	14s. 9d. ,, ,,
Coumarin	16s. ,, ,, advanced.
Citronellol	22s. 6d. ,, ,,
Citral, 100%	9s. 6d. ,, ,,
Ethyl Cinnamate ..	18s. 6d. ,, ,,
Ethyl Phthalate ..	4s. 3d. ,, ,,
Eugenol	11s. ,, ,,
Geraniol (Palmarosa) ..	30s. ,, ,,
Geraniol	5s. 6d.-12s. 6d. per lb.
Heliotropine	7s. 6d. per lb.
Iso Eugenol	17s. ,, ..
Linalol ex Bois de Rose ..	21s. .. ,,
Linalyl Acetate	22s. 6d. ,, ,,
Methyl Benzoate ..	8s. 6d. ,, ,,
Musk Ketone	35s. ,, ,,
Musk Xylol	9s. ,, ,,
Phenyl Ethyl Acetate ..	10s. ,, ,,
Phenyl Ethyl Alcohol ..	17s. 6d. ,, ,,
Rhodinol	45s ,, ,,
Terpineol	3s. 1d. ,, ,,
Vanillin	24s. 6d. ,, ,, advanced.

ESSENTIAL OILS

Almond Oil, foreign, S.A.P.	13s. 6d.-16s. per lb.
Anise Oil	2s.-2s. 1d. per lb. spot, 1s. 10½d. c.i.f. forward. Very quiet indeed.
Bergamot Oil	12s. 6d. per lb. spot. Will probably advance with the improvement in the lira.
Bourbon Geranium Oil ..	28s. per lb. spot. Substantial grounds for the advance difficult to find. Will probably decline when new crop comes to hand.
Camphor Oil, White ..	82s. 6d. per cwt. Quiet.
Cananga Oil, Java ..	9s.-10s. 6d. per lb. Quiet.
Cinnamon Oil, leaf, Ceylon	4d.-4½d. per oz.
Cassia Oil	8s. 3d. per lb.
Citronella Oil—	
Java	3s. 10d.-4s. 1d. per lb. Very firm.
Ceylon	3s. 4½d. per lb.
Clove Oil	7s. 9d.-8s. 6d. per lb. Quotations vary daily owing to fluctuations of the spice.
Eucalyptus Oil	1s. 6d.-1s. 9d. per lb. Steady but not much doing.
Lavender Oil—	
Mont Blanc	12s. 6d.-13s. per lb. for high grade oil. Expected to go dearer.
Lemon Oil, spot ..	3s. per lb., 3s. c.i.f. forward.
Lemongrass Oil	2¾d. per oz.
Orange Oil, Sweet, spot ..	10s. 6d. per lb. Distinctly a good market.
Otto or Rose Oil ..	20s.-32s. per oz., according to quality. A large quantity of very inferior otto offering.
Palma Rosa Oil ..	17s. per lb. Steady.
Peppermint Oil—	
English	70s.-80s. Quiet.
Wayne County ..	13s.-13s. 6d. spot, easier forward.
Japanese	6s. 6d.-6s. 9d. per lb.
Petitgrain Oil, Paraguay	7s. per lb. Flat.

TRADE NOTE

Sale of Plant

We call the attention of our readers to the important sale of plant and machinery announced on p. viii. The sale is to be held on the 24th, 25th and 26th inst. by direction of the Disposal and Liquidation Committee, which has appointed Mr. M. Marshall, of Glasgow, as auctioneer.

PUBLICATIONS RECEIVED

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council for Pure and Applied Chemistry

Vol. 42 NEW SERIES LONDON, APRIL 13, 1923 No. 15

EDITORIAL

THE title " Chemist " will form a splendid topic for a discussion, and a round-table conference such as is suggested by the President of the Society of Chemical Industry, should disclose a great variety of opinions. A preliminary exchange of views in these columns would, perhaps, save a little time. As no one can foretell the occasion when Parliament will, at the end of a session, adopt a hastily drafted phrase, including this term, as a compromise which will enable a bill to be rushed through in two or three crowded hours of a glorious life, the point is one not merely of metaphysical interest. There are at least two alternatives ; an effort may be made to put the word " chemist " into the same sort of category as " barrister-at-law," " solicitor," " civil engineer," or " dentist " ; on the other hand, some would like the word to be comparable with geologist, mathematician, or physicist. There are both advantages and disadvantages associated with either alternative, but the confusion between the two main uses of the word is at the moment less than might be expected. The chemists who are our readers form a social society, apart from the chemists, who dispense drugs, cough mixtures, and fragrant dentifrices. Each society uses the word in the particular sense usual in the circle and the two but rarely meet.

* * *

There are three bodies very intimately concerned in the skill and responsibility of the chemist who does not keep a shop. Such chemists are usually (i.) teachers ; (ii.) persons employed by a firm, or (iii.) consultants and analysts accessible to the public, and employed by a variety of firms or individuals. The requirements of these three are very different. Our universities commonly elect chemists on to their staffs either because they can make great discoveries which will bring renown to the university, or because they have the divine and rare art of teaching. It matters but little to the academic world whether the word " chemist " is rightly or wrongly applied to the professor, or to the vendor of patent medicines. Nor is it a matter of much consequence by what title a man is designated who is employed by one firm, whether in the most important, or an inferior capacity. If Messrs. A. B. and Co. employ as a chemist a man who has so little knowledge that no professional certifying body would admit him, that is primarily the concern of Messrs. A. B. and Co., and the man himself and we can imagine circumstances where the genius, tact, shrewdness or commonsense of the man would make him very valuable in a works. It is where the chemist is brought into contact with the public that the matter becomes of importance.

* * *

Any member of the public who consults a solicitor, and any solicitor who consults a barrister, can rely on a certain degree of professional knowledge. Negligence on the part of the lawyer is promptly punished. But no rules can ensure the existence of industry, sound judgment or skill in advocacy. Surely it must be the same in other professions in which men engage ; a title or a degree is strong presumptive evidence that a man has that minimum degree of knowledge, or that excellence of memory which enables him to pass a qualifying test, it is no guarantee of the power of looking into the future, of devising some ingenious way of evading an insuperable difficulty, or of that long experience which doth attain to something like prophetic strain. It is not quite apparent from the communications we have received, whether the true chemists wish to have for their own gratification, the title " chemist," implying some specified degree of knowledge, or whether they are desirous that the druggist shall cease to call himself a chemist or whether their real purpose is not that the man in the street, and especially the journalist, shall realise that there is a large and increasing body of chemists who are not concerned in any way with drugs, nor interested in infallible corn-plasters or blue pills. There are, of course, many important considerations we have not alluded to, and we think a full discussion of the matter, where a great variety of diverse opinions would be represented, would be full of interest.

ARTIFICIAL FATS AND FATTY ACIDS

By REX FURNESS

The problem of the technical production of fatty acids by true synthesis or by the oxidation of mineral oil fractions continues to attract interest, although the application of such fatty acids in the production of synthetic fats is perhaps not so energetically pursued to-day as it was at a time when edible fats were relatively scarce. The artificial production of a natural raw material in the factory always possesses an attraction for the chemist, and he automatically associates the problem of the manufacture of artificial fats and fatty acids with those of artificial silk, synthetic indigo and other triumphs of chemical technology. It might be as well, at the outset, to ask him to keep in mind also artificial or synthetic rubber, artificial cotton and similar materials, which, although undoubtedly capable of production, are outside the realm of economical technical manufacture.

There are four main considerations which must be discussed in the survey of the possibility of manufacturing fat substitutes and artificial fatty acids, namely :—

1. Truly synthetic fatty acids—made, say, from ethylene, acetylene, etc., or by the Grignard reagent from chloro derivatives of mineral oil fractions—cannot be manufactured at a sufficiently low cost. (*Cf.*, the analysis made by the writer, J.S.C.I., 1921, p. 63 R.)

2. The composition of mineral oils is still obscure, but recent investigations point very clearly to the relative absence of straight chain hydrocarbons from which to obtain fatty acids such as stearic, palmitic, oleic, etc., by cracking and oxidation. Empirical and opportunist investigation has indeed produced a fatty acid mixture from paraffin wax, and many are the contradictory claims made in this connexion. Practical scale production has not, however, been realised in Germany.

The problem is now being attacked in a more rational and scientific manner, and the laborious task of characterising the constituents of mineral oils, paraffin wax, etc., is well begun. Oxidation of definite hydrocarbons or hydrocarbon mixtures may lead to acids, which even if not identical with commercial straight chain acids, may find useful industrial applications.

3. Granting, for the moment, that artificial fatty acids could be produced economically, there still remains the question of esterification to produce fats, or fat substitutes. It is true that the esterification itself presents little difficulty, whether glycerin, glycol, ethyl alcohol, or a carbohydrate be employed, but the physiological value of the war-time German "esterol," or of the mannitan dioleate of Lapworth and Irving is indeterminate, as yet. Moreover, cost considerations again become vital, and it is clearly impossible at present to use glycerin, glycol or carbohydrates, for the production of fats from artificial fatty acids, at a price comparable with that at which natural oils and fats can be sold.

It should here be remembered that fatty acids themselves are not required to the same extent as are their esters, the glycerides, in modern industries. The glycerides or their equivalents are used in the paint and varnish industry, in the linoleum industry and in the leather industry, whilst compound lubricating oils require glycerides and not fatty acids, except for the small amount consumed in making compound oils by the Wells-Southcombe process, where a fraction of the amount of glyceride formerly employed is taken in the form of fatty acid. The edible oil trade demands glycerides, of course, and although soaps can be made from fatty acids by direct neutralisation by soda ash, the general public demands the brighter looking soap produced from the glycerides in the ordinary soap boiling pan. Fatty acids are required, however, in the candle-making business and in textile manufacture.

Thus, without going into a detailed examination of the matter, it will be clear that the main consumers of fat products demand the glycerides, and a successful process for fatty acid production from hydrocarbons would necessarily have to be followed by an equally successful and economic process of esterification. It may be possible to utilise fatty acid anhydrides—as edible products, but even so, technical production is difficult, and anhydrides could not be applied to the linoleum, paint or soap trades.

4. The production of natural oils and fats can be almost indefinitely increased. Improvements in seed selection, plant culture, fertilisers, insecticides, fungicides and germicides, and in all the phases of the art of arboriculture are constantly being made, and the price at which a natural oil or fat can be produced is steadily decreasing as oil yields increase. The supply is, moreover, annually reproduceable.

The technique of refining processes, hydrogenation processes, and other methods of transformation of natural oils is sound, and its scope is extending. Thus, it is claimed that drying oils can be made from semi-drying oils by dehydrogenation.

The supply of refined and unrefined, vegetable and animal, including marine animal, oils is capable of so great an economic expansion as to provide an almost insuperable barrier to the synthetic glyceride process, particularly if the fatty acids used in the latter process are to be made artificially.

It is proposed to discuss in some detail the second and fourth phases of the question, as indicated above, since the production of suitable fatty acids from such a cheap and plentifully available raw material as mineral oil is fundamental, and the solution of this problem must precede any attempt to manufacture cheap glycerin—say, by fermentation of sugar-glycol, ethyl alcohol; or "power" alcohol from ethylene, acetylene, or by fermentation of biologically saccharified cellulose, or of cheap starch-bearing plants.

The maximum extent to which production costs in respect of natural oils and fats can be lowered is also basic and relevant to the whole problem.

FATTY ACIDS BY HYDROCARBON OXIDATION

The lure of the cheap and plentiful petroleum oil fractions as a starting material for the manufacture of fatty acids by oxidation has been responsible for much sporadic experimentation. No practicable process has yet been evolved, although the published results of some investigations would appear to be promising.

The problem of the composition of natural mineral oils and waxes and of paraffin wax is now receiving careful study, and the investigations only serve to emphasise the difficulty of technical fatty-acid production from this source.

Several primary obstacles stand in the way of the development of a technical process for fatty acid production from mineral oils and similar materials, namely :—

1. The relative absence of straight chain hydrocarbons, and the differences in the behaviour of different components upon oxidation.
2. The apparent impossibility of stopping the oxidation at a stage when fatty acids alone are present or at a stage approximating to this sufficiently nearly.
3. The physical properties of fatty acids and fatty acid mixtures at present in use in soap making, candle making, etc., are known, following close investigation, and it is clear that unless identical acids and mixtures become available, that is, unless straight chain acids can be produced artificially, the natural acids will continue in favour.

THE COMPOSITION OF MINERAL OILS

It is becoming more and more realised that mineral oils, flowing from wells in different parts of the world, contain complex mixtures of hydrocarbons amongst which normal paraffins form but a small proportion. Even such a traditionally "straight-chain" petroleum as Pennsylvania crude has been shown by Mabery to contain a relatively small proportion of normal paraffin constituents. Naphthenic and polynuclear hydrocarbons are present, so that bromination number tests which indicate different degrees of unsaturation do not necessarily indicate the presence of easily oxidisable olefinic, straight chain hydrocarbons. Dunstan has indicated the impossibility of hydrogenating unsaturated mineral oils by the Sabatier-Senderens method, which, of course, is universal in its applicability to the ethylene bond compound. "Cracked" petroleums can, however, be hydrogenated, but the position of the double bond already existent in mineral oils or produced in an attempted cracking-oxidation process is so indeterminate that hope of the production of definite fatty acids by oxidation at the double bond can scarcely be entertained at present.

Francis (*J. Chem. Soc.*, 1922, pp. 496, 1529 and 2804) has demonstrated, after laborious experiments, that paraffin wax probably contains considerable amounts of hydrocarbons which are certainly not the normal, straight chain paraffins of our text-books.

Similarly, Granacher (*Helv. Chim. Acta*, 1920, 3, 721) finds the behaviour of paraffin and synthetic hendecane so different upon oxidation, that he concludes that paraffin wax contains forked chain hydrocarbons.

If, moreover, the enormous task of defining the various constituents of mineral oils be achieved, and a definite starting material be available for oxidation, the fatty acid product of this treatment could only become economically available if progressive oxidation were prevented. The splitting off of one carbon atom after another, and the production of heterogeneous mixtures, would lead to loss in the form of undesirable, low molecular, products, and to expense in the separation of the "sheep from the goats." Thus, the experimental results now to be indicated are relevant, and indicate the complexity of the product of the oxidation of simple compounds.

THE PROGRESSIVE OXIDATION OF HYDROCARBONS

Solway and Williams (*J. Chem. Soc.*, 1922, p. 1343) obtained the same products of oxidation from both hexadecane and stearic acid by air oxidation at 120°—130° C., in the presence of manganese stearate as catalyst. Fatty acids of the normal series, dibasic acids of the malonic series, lactones, lactonic acids, formic acid, CO_2, etc., were obtained, and it is concluded that the first product of paraffin oxidation is a fatty acid, which is obtained by oxidation at the double bond formed in the paraffin chain. Further, simultaneous action occurs, leading to products of lower molecular weight and of widely different nature.

An examination of the papers of Francis (*loc. cit.*) will indicate very forcibly the complex mixture of products, acids, oxygenated non-acid products, etc., which are obtained upon even a mild oxidation of paraffin wax. If it be borne in mind that technical production would demand a higher reaction velocity than can possibly be attained at temperatures about 100° C. (Francis), the complexity of the oxidation product can be well imagined. The many attempts reported from German laboratories to produce fatty acids during the war years demonstrate the number of acids, esters, waxes, oxy acids, etc., produced when temperatures of, say, 120°—150° C. are employed in order to attain a reasonable rate of hydrocarbon oxidation.

Hence, if the first difficulty be overcome and definite hydrocarbons are won from petroleum crudes—and it is apparent that careful and costly fractionation would be essential—the oxidation of these materials to definite acids is not a solved problem. The acceleration of a particular reaction is by no means impossible, but it is a problem in the scarcely trodden field of preferential catalysis—*cf.* the writer's article, *Chemistry and Industry*, 1923, p. 196.

NATURE OF THE FATTY ACIDS
